THE MODERN UNIVERSITY SCHOOL—ITS PURPOSES AND METHODS.

JOHN M. DODSON, M.D.
CHICAGO.

The earliest American medical schools were established in connection with institutions of general learning, as would have been expected from the fact that the physicians who founded them had been educated in Great Britain and France, where the medical colleges were, without exception, departments of universities. Only a few of the American schools, however, were established with such a relation, the larger majority being quite independent of any university or college connection, so that in 1877, twenty-five years ago, less than twenty of the sixty-five medical colleges then in existence were connected in any way with institutions of general learning. Subsequent to that date, however, such schools have become much more numerous, and of the one hundred and fifty-eight medical schools at present existing in America, between sixty and seventy are connected with a university or college.

These facts suggest some interesting queries. Why were not all of our medical schools, following the example of those first founded, established in connection with institutions of general learning? What motives have prompted the movement which, starting about 1880, has resulted in the large increase in medical schools so connected? What is the nature of the relationship which exists to-day between the medical schools and the universities with which they are connected? Has this relationship resulted in the largest possible measure of advantage to either the medical school or the university? And finally, what should be the nature of this relationship in order that the best results may be secured?

THE DIFFERENT CONDITIONS IN THE EARLY DAYS.

In answer to the first query it may be noted that there ere no universities in America in the broad, European ense until comparatively recent years. Our institutions of higher learning were as most of them still remain, colleges, devoted to purely academic instruction, n the classics, mathematics and philosophy. Such an stitution has nothing in common with the professional hool, and there can be little advantage or propriety ny connection between them. Then, too, it was ly possible to establish the medical school on such sis as to make it a fit member of a university organ- The rapidly-growing country demanded phy- s in large numbers, trained as best they might be practical life, but with requirements and the ex- e of the college course such as not to place it beyond the reach of all but a few students. Until the middle of the last century the majority of students entered the practice of medicine through an apprenticeship with a preceptor. The chief problem was how to induce these students to spend any time at all in the medical school, and to have exacted high requirements for admission, and a prolonged and expensive course would have been to defeat the very purpose for which the school was established. But a college with such standards, little or no restriction as to preliminary education, graduating after attendance on two, four or five months' sessions of repetitional lecture courses, could not fittingly have been made a department of a true university.

Thus medical colleges came to be established by medical men as independent institutions, sometimes, it is true, with other than the highest motives, but, on the whole, with an honest purpose to meet a real need. In passing judgment on these colleges and their founders due regard must be taken of the conditions which obtained at the time they were organized. In the absence of endowment or financial aid from the state the college had no resources excepting from the fees of students, which were of necessity low. It was imperative that the standards of the school should be such as to insure a sufficient number of students to maintain it on a working basis. For the past twenty-five years there has been no real demand for more medical colleges, and the judgment if not the motives of those who have instituted most of the colleges established within this period may well be questioned, but previous to that time the physicians who established the medical colleges of the old type were, with few exceptions, animated by an honest purpose, and possessed a logical and discriminating judgment in adjusting the standards of education very closely to the needs and conditions of the times. These institutions, sometimes styled commercial, never, so far as I have knowledge, yielded a direct money profit, though the indirect return to the occupants of the clinical chairs was in many cases large. Fortunately, the demand for physicians is no longer such as to compel the maintenance of schools with low standards.

THE TRUE UNIVERSITY.

The true university dates its inception in America from the founding of the Johns Hopkins University, which within a few months has celebrated its twenty-fifth anniversary. From this institution, with its emphatic pronouncement that the extension of knowledge by original investigation must constitute the very essence of the true university, can be directly traced the origin of the university idea in this country. Soon Harvard, Yale, Columbia and Pennsylvania caught th new spirit, and the founding of the Clark University the early '80s, with the growth of Cornell and some of the state universities, gave evidence of the fact that the university idea had taken deep and abiding root in American soil. Unfortunately, however, many other colleges, entirely lacking the means, the men or the equipment essential for true university work, stimulated by a feeling of rivalry, became ambitious to pose under the larger name. Mistaking mere multiplicity of departments and a large enrolment of students as the essential features of the university, they promptly became, by a mere process of rechristening, nominal universities. Naturally the next step was to institute professional departments, and, as in many cases, colleges of law, medicine, dentistry, pharmacy and the like, already established and prosperous, were located in more or less close proximity, the ambitious university found it much easier to expand along these lines by a process of amalgamation than by the creation of wholly new departments. The professional schools were, in most cases, more than willing to enter into such an alliance, for they, too, had caught the university idea in the same superficial way, and had come to feel that a university connection of some sort was the order of the day, and that the medical school must be so connected to be in vogue. Yet another motive was found in many cases in the rapidly-increasing cost of maintenance. The introduction of laboratory methods, the necessity for salaried teachers in the fundamental branches, and for the maintenance of hospitals and dispensaries to provide adequate clinical material had increased the cost of the medical course beyond the student's ability to pay for it even when the fees were increased to twice those formerly charged. It was obvious that governmental aid or private endowment must be had and that this could seldom be secured by the medical college as an independent institution.

THE NOMINAL CONNECTION WITH A UNIVERSITY.

The character of the relationship, however, which exists between the college or university and the medical school has been in the large majority of cases purely nominal, as evidence of which a specific case will serve. I have in mind an institution which blossomed forth in a few months from a college with less than four hundred students into a university with an enrolment of nearly twenty-five hundred. An analysis of the student list, however, discovers the fact that about eight hundred of these students were in the medical college, which had added to its title "The Medical Department ——— University," over four hundred were in a dental college, similarly allied, some two hundred in a law school, and a large number in a school of pharmacy. The number of students in the actual collegiate departments had not increased nor had the number of members in the faculty, while the courses offered and the character of the work done had not been materially altered. And what was the nature of the union between this "university" and its constituent professional schools? Purely nominal. They had not surrendered one iota of their autonomy. The separate board of trustees and faculty were in each case retained intact, having entire and unrestricted control over the finances of the professional school, of appointments to its faculty, of the standards of admission and graduation, and of all its other affairs. These departments were located several miles from the university, and the only visible evidence of their connection with it, aside from the printed line on the announcements and letter heads, was the appearance of the president of the university to con-r the degrees at the annual commencement.

While this example represents the extreme degree of looseness in such a connection, it differs only in a degree from that of the large majority of the medical schools now connected with universities in this country. May not the real value of such an alliance, to either the university or the professional school, be fairly questioned? There has been a disposition to attribute to these university connections the rapid progress which has taken place in medical education in recent years, but it is difficult to conceive how such a purely nominal relation can have had much influence in this regard. This progress, comprising the elevation of the standards of admission and graduation, the lengthening and grading of the curriculum, the introduction of new branches and of improved methods of instruction, has come about as the inevitable result of the advancement which has been going on in all lines of education. The development of the true university and of the university spirit in America has had much, indeed most, to do with it, but not through any such nominal relationship as in the case above cited. It is a singular fact that even in the older medical schools, which were from their inception university departments, the relation of the medical with the general faculty has had so little of unity or intimacy about it. The medical department is usually removed by some distance from the university proper, the faculties never meet together, and in almost every respect the medical school is conducted as an independent institution.

THE PROPER RELATIONSHIP TO THE UNIVERSITY.

The largest service can never be accomplished by the medical school nor can the fullest measure of advantage result to it or to the university from such a purely nominal relationship. What, then, should be the nature of the union between the medical school and the university of which it is a part?

It must be made an intimate, integral part of the university. Its financial management must be given over wholly to the board of university trustees, a body of laymen with large business experience, deriving no pecuniary advantage from this position and commanding the fullest confidence of the community. Only by such an arrangement, and the assurance of wise and disinterested management which it affords, can private endowment be successfully invited. It would be of distinct advantage to the university to have at least one medical man on this board of trustees. The medical teachers must be members of the university faculty, sitting in its councils and having a voice in the educational policy of the whole institution, while, on the other hand, the conduct of the medical work should be subject to the advice and approval of the general faculty.

THE FUNDAMENTAL BRANCHES.

The teaching of the fundamental medical branches which constitute the first two years of the curriculum, as now arranged, should be conducted in the corresponding university departments of physics, chemistry, anatomy, zoology, physiology and bacteriology. Even pharmacology and fundamental pathology should be so taught, for in the widest and best sense these sciences are branches of general learning and should be provided for in the university quite apart from their medical significance. The advantages of such an arrangement are many and important. It will obviate the expensive duplication of departments as they exist now under the prevailing system. Most of these branches are at present taught in the university proper, in well-appointed laboratories, by men who are devoting their lives to research and teaching in their respective lines, yet at the medical school of the same institution this expensive equipment is duplicated and another corps of teachers employed, either on a similar basis, or more often as men who are primarily practitioners of medicine, only incidentally teaching these subjects in a perfunctory way while waiting for some incumbent of a clinical chair to vacate by death, resignation or otherwise, and thus make possible the fulfilment of their real ambition. Of more importance is the fact that these subjects can only be taught in the right way in the university proper, for only there can they be so pursued as to lay a broad, thorough foundation for their subsequent application to clinical medicine.

MEDICINE AS APPLIED SCIENCE.

Medicine is applied science. Its practice consists in the application of the principles, facts and methods of chemistry, anatomy, etc., to the study and treatment of the diseases and accidents of the living body. In the pursuit of any applied science it is surely the logical method to master the general principles and methods first and to proceed therefrom to a study of their application in any specific direction. Fundamentally the chemistry which the physician needs to know is quite the same as that required by the metallurgist, the manufacturing chemist, the pharmacist, or one in any other vocation where chemistry is concerned. It is only in the application of chemistry along these special lines that the methods differ.

The medical school has for years been attempting to teach its students the fundamentals of chemistry and their specific application at the same time. In the short course of two five months' sessions there seemed to be no escape from this. But what was the result? The student, crowded for time and jealous of every minute, sought to learn, as his professor sought to teach him, those isolated facts of chemistry which seemed, at the time, to have most direct bearing on medicine. Yet no teacher, however wise, much less any student, could possibly anticipate the chemical knowledge which might be of medical import a few years in the future, in the rapidly-progressing art and science of medicine. The result was a half knowledge mostly soon forgotten. If the medical man is to have a groundwork in chemistry which will enable him to keep abreast with his profession, he must be so trained in the fundamental facts and principles as to enable him to keep in touch with the advances in that science, to read its literature intelligently and to apply the frequent new discoveries to his daily work. To illustrate: ten years ago the remarkable facts of physical chemistry relative to the behavior of mineral salts in very dilute solution—the so-called ionic condition of matter—would have been pronounced by any chemist as among the most theoretical and impractical facts of that science, yet already the investigations of Loeb and his pupils have demonstrated these facts to have a most important bearing on physiology, pathology and pharmacology. Indeed, it is not too much to say that these facts of physical chemistry, which we owe to Arrhenius and van t'Hoff, offer an apparent promise of a solution of more problems in the fundamental and practical medical sciences than any others now known to us. Few physicians trained by the older methods of the medical school, have been able to keep pace with these developments or even to read them understandingly, but to the medical man who received an adequate training in chemistry in a college or university, they present little difficulty.

What has been said in reference to chemistry is equally true of anatomy, both gross and microscopic, of neurology, embryology, physiology and physiologic chemistry, of bacteriology and pathology. Studied primarily in the atmosphere and by the methods of the university the ground-work of these sciences is laid in a broad and comprehensive manner which enables the student to follow their progress in later years and their specific application to medicine and surgery is easily acquired. Pursued in the illogical, unsystematic manner of former years, they are never mastered and too often the physician soon awakes to the unpleasant consciousness that the facts acquired at such a laborious expenditure of time and energy have most of them flown from his memory. Not only has he failed to keep abreast with the newer knowledge—he has forgotten the old. Life is too short and time too precious to be wasted in memorizing facts that must soon be forgotten.

THE BENEFITS OF THE UNIVERSITY ATMOSPHERE.

Great benefit will come to the student from two or three years spent in the atmosphere of the university in the daily companionship of men who are masters in their several departments and who, as investigators, are seeking to add new knowledge by their own discoveries. The spirit and method of the research worker is exactly that of the successful practitioner of medicine whose every case is a problem, never exactly like any other that has been met before. Such problems are never satisfactorily solved by routine rules of diagnosis and treatment, but only by the exact painstaking examination of the facts in the particular case and the application thereto of the principles of anatomy, physiology and pathology. The successful practitioner is he who is most completely a master of this "investigative" ability, and who avoids most effectually the pressing temptation to become a "routine" doctor.

Of the influence on the student of the social and intellectual life of the university it is hardly necessary to speak. No environment is more conducive to the development of a strong, broad-minded influential man and citizen, and that is what we would wish every physician to be. The transfer of the teaching of the fundamental branches to the halls and laboratories of the university proper, will do more toward the creation of a strong and influential profession than any other plan that has yet been tried. For this reason, and because it is adaptable to so many medical schools, it seems to me to be the most progressive and far-reaching movement which has yet been made in medical education.

THE PURPOSES OF THE UNIVERSITY MEDICAL SCHOOL.

The purposes of the university medical school, organized on the lines indicated, will be broader and more comprehensive than those of the existing medical schools because of its larger facilities and possibilities. They may be briefly summarized: 1. The preparation of men for the practice of medicine—undergraduate instruction; 2, the training of selected students for teaching and research work; 3. to offer opportunities for practitioners to keep pace with the advance of medicine—such as are now afforded by the policlinic schools; 4, the preparation of men for public health service; 5, to extend the bounds of medical knowledge by affording opportunity and encouragement for research work; 6, to investigate and pronounce authoritatively on alleged new discoveries bearing on medicine, and 7, to educate the public along medical lines by the methods of university extension.

THE UNDERGRADUATE STUDENT.

The preparation of young men for the practice of medicine in the usual sense of the term, must always constitute the largest and most important function of the university medical school. And by this is meant the education of students for the humblest as well as the most exalted walks of the profession. Time was when the college or university was an exclusive institution, whose members were disposed to feel themselves removed from the world at large, set apart for certain special and exalted duties. Happily that time is past and the modern university seeks above all things to keep in touch with and to supply the needs of the world of affairs, wherever and whenever it can do so. Witness the rapid growth of the university extension, of correspondence courses, of short courses in agriculture, pedagogy and the like, and of the establishment of departments of agriculture, economics, banking and commerce, journalism and other ultra-practical branches.

THE STANDARDS OF ADMISSION.

The attitude which the university medical school assumes in regard to this matter will largely determine its standards of admission and graduation. While the university must stand always for the highest practicable requirements, it seeks not to cut itself off from the education of men who are needed for the work of the world by placing these standards beyond the reach of all but a few. Its requirements must be adjusted to the conditions of the times and be gradually raised as the community is educated up to their endorsement and to the adequate appreciation and support of the men whom the university has trained. It would be a great misfortune if the university medical school were to confine itself to the instruction of the select few who would find adequate recompense for their expensive training only in the higher walks of professional life. Such a policy would inevitably result in a wide and ever widening breach between the few schools of this class, and the great number of medical colleges with low standards, to whom would fall the teaching of the rank and file of the profession.

We hear much of an ideal standard of admission to the medical school. And what may that be? Surely not the bachelor's degree, for as conferred in this country by the thousand or more institutions empowered to grant it, it is no standard at all, its significance ranging from less than many high school diplomas to that conferred by the highest grade universities. One institution, to my knowledge, admits students from the grammar school, confers a bachelor's degree after two sessions of fifty weeks each, allowing the student during the same period to complete the course for the degree of Ph.G. If knowledge of certain specific branches be demanded in addition to the bachelor's degree, may it not well be asked why, if these are the essential things, the degree should be made a prerequisite at all?

The degree which affords the nearest approach to an ideal is that of Ph.D. This degree has been guarded with much more care in America than any other. It certifies, when from any standard institution, that the student has not only pursued a seven years' course of collegiate instruction, but that he has given evidence of capacity as an investigator—of the very qualities of mind, indeed, which are most demanded in the study and practice of medicine. But would any one contend that such a requirement could reasonably be exacted of all candidates for admission to the medical college under the conditions and emoluments of private practice at present in vogue? Such a demand would be "ideal" under ideal conditions and an ideal appreciation by the public, of the physician's merit and the compensation due him, but the truly "ideal" standard, in the most useful sense of the word, is that which best fits the graduate in medicine for the conditions of his time, and this must be, for a long time to come, not a fixed but a gradually increasing standard.

THE TRULY IDEAL STANDARD.

And what may be fairly demanded under existing conditions? Bearing in mind the readiness with which the medical schools have met the rapidly increasing demands of the last decade—demands, in large part created by the schools themselves—there can reasonably be exacted in the near future, by every medical school, a four-year high-school education, and, in addition, two years of college work, insisting that this be partly in chemistry, physics, biology, mathematics, English, German and French—branches which are especially needful as a preparation for medical work. And with such a preparatory course the student can procure the bachelor's degree in the university medical school by applying his credits for the first two years of his purely medical work on the course for that degree, without in any degree doing violence to existing university procedure. The fundamental medical branches, if taught in the university itself, by university teachers and university methods, have quite the same culture value as have geology, astronomy or any of the other sciences, and credits for work in these branches should count on the scientific or arts course in exactly the same way. Under such an arrangement the average student is able to secure the degrees of B.S. and M.D. in from six to six and a half years from the date of his entrance to college, should begin his medical work at the age of 21 or 22, and be launched into practical life, with a year of hospital training, at 26 or 27. The problem of launching young men into professional life with an adequate training at an earlier age than has been possible under the existing methods, has been much discussed by leading educators. In some of our best universities the course for the bachelor's degree has been shortened to three years. The plan here outlined, of telescoping the literary or scientific with the professional course, where they so nearly correspond, seems to offer a much more logical and satisfactory solution. The advantage to many students of a complete collegiate course of four years, as precedent to the medical school, is clearly recognized, and every inducement should be offered such students to prolong their course of preparation. The right of any school to insist on a four years' college course as a standard of admission may not be gainsaid. It is only meant to contend that it would be unfortunate for the community if all of the high-grade schools were to adopt such a policy.

Should any special medical degree be conferred on the student who has presented a bachelor's degree for admission? Not unless he gives evidence in his medical course of the superior capacity and attainments, which he should have derived from his longer course of preparation. And, if he does this, if he manifests the investigative ability, and accomplishes research work in the medical branches similar to that which is demanded for a master's degree or the degree of doctor of philosophy, one of these degrees should be conferred.

THE PREPARATION OF THE TEACHER AND INVESTIGATOR.

Recent changes in the methods of medical education have greatly increased the demand for men who have been especially trained for the work of teaching and investigation and who prepare themselves with the intention of devoting their lives to such work. Not the least, therefore, of the functions of the university medical school will be the education of this class of students. And how shall these students be selected? Shall the entrance requirements for these pupils be different from those exacted of the larger group who are preparing for the practice of medicine? I believe not, for no plan of examination can ever enable a faculty to select such men so wisely as will the observation of their daily work in the regular course of instruction. One of the most capable and successful investigators and teachers whom I have known possessed only a high school diploma when he entered the medical school, yet in his sophomore year he accomplished a piece of research work which would have done credit to a doctor of philosophy, and immediately after his graduation he was appointed to a responsible university position, which he fills with distinction. It is not at all certain that this young man has done an unwise thing in foregoing a collegiate career. True, his case is somewhat of an exception to the general rule, but provision must be made for such exceptions. Furthermore, it is of mutual advantage to the research worker and to the ordinary student, that they be educated in the same institution and in daily contact with each other—to the ordinary student because it is of the greatest advantage to him that he should be in the atmosphere and should catch the investigation spirit; from the standpoint of the research worker because the selection of such men can best be made from large groups of students who are revealing their special abilities and characteristics to their teachers in their daily work.

THE UNIVERSITY POLICLINIC.

In every progressive occupation, reports of progress from all over the world find their way most quickly to the large centers and men who are themselves engaged in teaching and investigation are most likely to keep informed as to the new discoveries which are being made. The physician engaged in a busy practice, far removed from such a center, finds it difficult, even with the abundant current literature and the aid of a good library and laboratory, to keep thoroughly abreast of the times. He finds it of advantage, therefore, to seek such a center from time to time, to spend a few weeks in special postgraduate study. The necessity for this sort of review on the part of the general practitioner has been especially pressing during the last few years, owing to the enormous and rapid advance of the medical sciences. How great has been the demand for facilities in this direction is evidenced by the large number of policlinic and postgraduate schools which have come into existence since 1882. These institutions have met a real need and have been of great service, but it is not too much to say that they have not been organized on the best possible basis nor do they offer facilities for the highest kind of work. A great variety of work is demanded by these policlinic students; some need courses even more fundamental than the ordinary undergraduate, for whole new sciences, like bacteriology, have been created since these gentlemen took their medical degrees; some few are really competent to enter on the study of and preparation for a specialty, while a few have the necessary equipment and qualities of mind demanded by research work of a high order. To adequately supply these various demands, needs an institution of large resources, a large faculty, and very large hospital facilities. Only the university medical school has anything like the equipment necessary for this work, and the instruction of practitioners, in the broadest, most complete manner, will constitute one of its important functions. The university policlinic will not be conducted on the "Make-a-specialist-of-you-while-you-wait" policy that has too often prevailed, but for the sound and legitimate purpose of enabling the practitioner to continue his student-life, and to keep in touch with the new knowledge and improved methods so that he may utilize them in his daily work. Its laboratories and libraries will be at all times open to the physicians in proximity to the university that they may the more thoroughly and exhaustively study their cases by the methods and apparatus and the literature not otherwise at their command.

THE EDUCATION OF THE SANITARIAN.

Courses in state medicine and sanitary science are a pressing need of the time. Preventive medicine has profited far more than curative medicine by the discoveries of recent years, especially in bacteriology. Our hope for the future lies in the education of the public in regard to matters already well known to the profession, in the enactment of suitable laws, and in the efficiency of properly trained health officers, city, state and national. State medicine constitutes a distinct specialty and its successful pursuit demands a particular course of study which should extend over at least two years. Nowhere can the facilities for such a course of postgraduate instruction be adequately afforded excepting in the university, with its many departments, its large corps of trained investigators and teachers, and its well-appointed laboratories. In the department of geology, there may be studied the character of rocks and soils and of physiography in their relation to water supply, drainage, sewage disposal, and the like; in the department of chemistry, instruction in water analysis, toxicology and the chemistry of food and drug adulteration, will be offered; in the department of zoology, a knowledge may be acquired of animal parasites and of the microscopic examination of animal foodstuffs for their detection; the department of bacteriology will occupy a conspicuous position in this course in state medicine for the study of the bacteriologic examination of water, of milk, and other foods, and the detection of the various pathogenic organisms; the theories and methods of disinfection should be fundamentally studied; in the department of pathology, connected as it must be with a large hospital, there will be taught the methods of conducting a postmortem examination, especially in connection with medicolegal cases. And, finally, practical instruction must be afforded, in the health department of the city itself, in such matters as house inspection, the testing of sewer traps and other plumbing, public vaccination, the detection of cases of infectious diseases, the institution and maintenance of quarantine, the registration of vital statistics, the best methods of educating the community by the circulation of pamphlets, through the public press, and otherwise. There are few health officers who would not heartily coöperate with the university in offering such facilities as this, as these students can be of great service to the health department in the conduct of its daily work, and they would thus make abundant return for the instruction received.

THE PROMOTION OF RESEARCH WORK.

The obligation of the university and of everyone connected with it, to extend the bounds of knowledge by independent research, is now universally recognized. Investigation of the unknown as distinguished from mere appreciative study of the work of others, constitutes the keynote of the modern university, and this will be no less emphatically a feature of the medical than of its other departments. Investigation is essential, however, not simply that the bounds of knowledge may be extended, but that the spirit and method of research may be inculcated in every student. It is important that this fact be kept in mind for a thorough appreciation of this purpose will affect most decidedly the attitude of the teacher toward his pupils. He is not discharging his full duty nor doing the largest service when he confines his attention and devotes his best energies to the few selected students who demonstrate special capacity for such work and give promise of developing into competent investigators. Naturally, his interest will be especially aroused in this group of pupils. but he has no less an obligation to inculcate the same spirit and to train in the same methods of work the less capable individuals who are preparing for the ordinary practice of medicine.

RESEARCH IN THE CLINICAL BRANCHES.

In several American universities superior opportunities for investigation in the fundamental medical sciences of anatomy, physiology, chemistry, bacteriology, pharmacology, embryology, physiological chemistry, and pathology, are now afforded, and research work of a high order is being conducted in these branches. Quite as important, however, are the clinical branches of medicine and it remains for the university medical school to provide the men and the facilities to take up research work along these lines. This means, in the first place, the provision of a corps of teachers in each of the clinical branches who, divorced entirely from the labor and distractions of active practice, may devote themselves unreservedly to teaching and investigation in their several departments. This does not by any means imply that there will be no place in the faculty of such a school for the teacher who is at the ame time a practitioner of medicine. Medicine, as has been said before, is an applied science and in its teaching force there will always be need of men who are daily engaged in the application—the regular practice—of their vocation. A large part of the necessary instruction of the student can only be accomplished by such teachers. Nor will the active practitioner be excluded from the privileges and obligations of research. Most of the advances in medicine which have been made up to the present time have been accomplished by physicians in active practice. Doubtless some of these men might have accomplished more in the way of discovery had they been freed from the exacting duties of practice, but we may not say this of them all. Some of these discoverers doubtless found in the conditions of their daily work the very incentive and environment which was essential to their investigations. Certainly this has been true in the other applied sciences, as, for example, in electrical, mechanical and chemical engineering, some of the most important discoveries in which, not only in methods of application, but in fundamental principles have been made by men who were practicing engineers.

In the second place, investigation in the clinical branches demands the provision of special hospitals, absolutely under the control of the university, perfectly equipped and adequately supported, where patients may be studied under conditions which have not yet obtained in full measure in any hospitals with which I am acquainted. It will be of advantage, if there can be brought together in such a hospital, from time to time, groups of cases of the same or allied disorders. What might not be discovered, for example, from an exhaustive study of a group of forty or fifty cases of diabetes mellitus, gathered in one building for a few months, where the condition could be absolutely controlled? That every such hospital must have abundant laboratory facilities and a corps of trained assistants goes without saying.

THE INVESTIGATION OF ALLEGED DISCOVERIES.

From time to time there arise in medicine fads and 'isms and 'pathies, loudly heralded by their promulgators as the only and long-awaited panacea for all the ills that flesh is heir to, and such has been the history of the world since time began. Many such claimants for popular credence carry their own refutation and are no more worthy of investigation by the university than would be the claims of the newspaper weather-prophet or the street-corner astrologer and horologist. Some of these passing fancies, however, take a strong hold on the public mind, and much harm results, before the utter falsity of the fad is demonstrated, or, possibly, the small kernel of truth winnowed from the mass of chaff. Often it would seem as if the credulity of the public were in direct ratio to the absurdity of the claims of the system. The fancied division in the public mind of scientific medicine into so-called "schools," and the supposed animosity of the adherents of these schools toward each other, has precluded the possibility of any investigation and pronouncement from the independent medical college having any considerable weight or authority. May not the university with its large faculty, representing many phases of thought, and free from the suspicion of prejudice, perform an important service to the community by the impartial investigation of such claimants as seem at all worthy of serious consideration, and a candid statement of the facts? In the broad open spirit of liberality and desire for the truth, which should characterize the university, the advocates of any new system or 'pathy might properly be invited to present their claims before the faculty or a commission to be selected for that purpose. Such an investigation as that conducted under the auspices of the University of Pennsylvania a few years ago—the Seybert Commission for the investigation of spiritualism—occurs as an illustration of the thought here presented.

UNIVERSITY EXTENSION AS RELATED TO MEDICINE.

If the beneficent results to the recent enormous advance in our knowledge of preventive medicine are to be realized in any large measure, this can only be by means of the education of the public in matters of personal and community hygiene. The medical profession has been remiss in this direction, but this has been in large part owing to the difficulty of addressing the public without violating the established ethics of the profession. The practitioner, competent to give instruction, has hesitated to do so because of the certain imputation of ulterior motives, the charge that he was seeking to exploit his knowledge and so secure his own aggrandizement. A great work awaits the university medical school which it can accomplish by adapting to this purpose the university extension methods, which have been so successful in other branches of learning.

Especially available for this service as lecturers and writers will be those members of the medical faculty who are not engaged in active practice, and to whom, therefore, no suspicion of improper motives can attach. The vital and well-established facts in reference to infectious diseases, etc., advice in reference to personal hygiene, clothing, food; the abuse of intoxicants, the need of legislation in reference to sanitary matters and the enormous possibilities of wise enactments—these are but some of the items which may be effectively presented to the public by means of the university extension and correspondence courses, articles in the newspapers and popular magazines, and through other avenues of instruction. Existing organizations like the social clubs for either sex, university extension centers, churches, and the like, may be readily utilized in this work.

THE METHODS OF THE UNIVERSITY MEDICAL SCHOOL.

The methods of the university medical school will differ in some respects radically from those which have heretofore obtained. While didactic and so-called clinical instruction to classes of 200 or 300 students may continue to have place, that place will be a very limited one. Students must be taught singly or in small groups in the laboratory, at the bedside, and in the dispensary, where they may train their faculties and acquire knowledge at first hand by seeing, hearing and handling things, instead of at second-hand by merely reading or hearing what some one else has had to say about them. Then, too, education and not the imparting of information will be the prime subject of instruction. In the ten months formerly available there seemed so much knowledge to impart that there appeared to be time for little else, but with the thirty to thirty-six months now occupied by the medical course, and with the obvious impossibility of imparting any considerable fraction of our medical store in thrice that time, it has come to be realized that the actual facts selected for the student's acquisition are of minor importance, but that it is a vital matter that he acquire the ability to observe accurately, record clearly and concisely and to think logically along medical lines. This means that the scheduled work of the curriculum must consume fewer hours of the day—never to exceed six—that the remainder of his working day may be spent in the library, or in his room learning to use medical literature properly, to write clearly and to think! to think! to think! It is surprising how absurdly overcrowded, and how utterly unbalanced the curricula of most of our medical schools have grown. In not a few of them, eight and even nine hours of scheduled work being daily demanded.

THE ELECTIVE SYSTEM.

Nothing offers a more ready and satisfactory solution of this difficulty than the elective system—so long and successfully in vogue in some institutions of general learning and recently adopted, in whole or in part, by some medical schools. It may be defined as that plan by which a student, pursuing a course for a degree, is allowed some choice in the studies he shall pursue, in his methods of study and of the teachers who shall instruct him; to adapt, in a word, his course of study to his tastes, his ability and his needs. It finds its *raison d'etre* in two fundamental and obvious facts: the vastness of knowledge and the variability of individuals. If it were possible to encompass all medical knowledge within the limits of a four years' course of study, or if it were possible to select for all students alike those facts which are most essential for every one of them to know, then the question of curriculum would present little difficulty. Neither of these things is possible and therefore the items of information which are acquired by each student, exclusive of a few of the fundamental and important truths in each branch, are not of necessity nor with advantage, the same for each student. On the other hand, students differ very widely in mental make-up, and no plan of education can be successful in developing the best there is in each man which fails to take cognizance of this fact and adapt its course of preparation to each individual, or, rather, to permit the student to so adapt it by the election of his work with the advice and approval of his instructors.

It will be no purpose of the elective system to make specialists of the undergraduate student, and any tendency in this direction may be readily avoided. It is unfortunate that the term "elective" should have been used in such a restricted sense by some writers as applying only to a system where the student is allowed absolute freedom of choice as between major branches. All of the advantages of election may be secured in full measure by requiring a specified minimum of work in each branch, as in anatomy, physiology, medicine, surgery, obstetrics, and the like, but permitting choice as to topics, methods of study and of teachers. Such a demand together with the requirement of the approval of a dean or other officer of the registration card, and the subjection of the student to a thorough practical examination in each of the major subjects, previous to graduation, affords a perfect safeguard against this abuse. Moreover, the good sense and judgment of the student himself, which teachers are prone to underestimate, are, in themselves, a sufficient safeguard.

I have elsewhere discussed the merits of the elective system as applied to medicine.[1] and the limits of this address preclude a fuller presentation of this important topic at this time. It will suffice to say that in the medical schools where it has been adopted on the most liberal lines, it has proven eminently satisfactory and has been demonstrated to be quite as decided an advance in the medical as in other departments of education.

THE CONTINUOUS SESSION.

The continuous session, in one form or another, will be a conspicuous feature of the university medical school; that is to say, the school will be in session, with perhaps slight intermission throughout the year in northern climates where work in the summer months is feasible. A board of trustees composed of business men will be little likely to allow an expensive plant to lie idle three or four months of the year, any more than they would close a manufacturing plant, representing an investment of several millions of dollars, for a like period. And this does not mean that only special or supplemental courses for teachers, physicians or students will be offered during vacation period, but that full work will be done throughout the year, exactly the same during the summer months as at other periods. Such a plan is scarcely feasible except under the elective system, for reasons sufficiently obvious. The continuous session is especially advantageous to the self-supporting student, who may often find it more convenient to devote the winter months to some bread-winning occupation. It is, moreover, of assistance in subdividing the classes, especially for clinical work, which can only be done satisfactorily in small groups. Many diseases, too, are to be seen and studied in the summer which are peculiar to that season. The continuous session will enable the ambitious, progressive student to shorten the period between his matriculation and graduation, and this ought to be made possible. It is true that this is in contravention of the present medical practice acts and of the rulings of the several state boards of medical examiners—rulings which seemed necessary to correct a serious evil at the time they were passed, but there is no logical defense for the present chain and halter method of hitching students together and compelling all to go at an unvarying pace. A certain minimum amount of accomplishment should be demanded, but while one student might require five full years to complete such a course, another may do it equally well in three, and he should be permitted to do so. Alexander Hamilton completed a law course, ordinarily requiring three years, in four months—an extreme exception, to be sure, but illustrative of the great difference in power of accomplishment between individuals.

---

[1] Bulletin of the Am. Acad. of Med., July, 1900.

The same laboratory methods which have been so successfully applied to the fundamental branches must be utilized in the teaching of the clinical branches, and this means that the medical school must have hospitals—not necessarily large—under its absolute control and available for research work in the clinical branches by all modern methods. It means, too, that some of the clinical teachers will be wholly engaged in teaching and research work to the exclusion of practice, and an adequate corps of trained assistants, both in laboratory and clinical lines. The clinical faculty will, therefore, comprise two classes—those who are exclusively devoted to teaching, research work and hospital practice, and who are adequately compensated therefor, and those who are in active practice—both hospital and private, but who devote a portion of their time to teaching and investigation.

THE EXTRAMURAL CLINIC.

While the university must have research hospitals under its own control, the amount of clinical material which is required for the large number of students is so enormous, and the expense of maintaining large hospitals so stupendous, that it seems unlikely that the millions of money which such a plant would require will be within the control of the university in the near future. But even with unlimited means, it would be poor business policy to neglect the large amount of clinical material already available in existing hospitals, but unutilized for teaching purposes, and especially would this be unwise in view of the fact that the use of these patients for teaching purposes is certain to be of great advantage to the patients themselves. No patients are so exhaustively examined, so carefully studied and so well treated as those who are the subjects of clinical teaching.

In almost every large city are hospitals in which the members of the attending staff are anxious to teach; and students are sorely in need of clinical material. All of this difficulty may be adjusted by a system of extramural clinics. Needless to say that the members of the several staffs who are appointed to extramural positions should be selected with due reference to their capacity as teachers and investigators, and never should one be given such an appointment merely because he can command a large amount of clinical material. By judicious effort in many cases the appointment of competent men can be secured to hospital staffs to the betterment of the clinic and the advantage of the patients, as well as for the extension of the extramural work. The removal of these hospitals by some distance from the college is not an insurmountable objection, for students will cheerfully go a considerable distance to receive such opportunities if the courses are only so arranged that the time spent in going and coming be not too great in proportion to the hours occupied by the course. It is usually best to arrange these courses so they will occupy a half-day. In the very large cities the establishment of two or three clinical centers, where students may remain in residence for the whole or part of the year, will enable all of the hospitals to be easily reached. Extramural teaching is only possible under the elective system, where credit is given for the work on the course for the degree, for the student's time is too fully occupied to permit of his giving much time to work which carries no credit. The control of very large charity hospitals by political appointment should be no discouragement, for by the combined and persistent efforts of the faculty, aided by the influential men of the board of trustees, even these obtuse politicians can sooner or later be convinced of the enormous advantage to the institution and its inmates of this kind of service.

The necessity for great care in the courteous and careful handling of patients needs to be strongly emphasized, for nothing will be more certain to prejudice the public against clinical work of this kind than a harsh, discourteous manner on the part of the clinician, the undue and unnecessary exposure of the body sometimes resorted to, or the granting of too great liberty to the thoughtless student. An undergraduate should rarely be allowed to examine a patient except in the presence of an instructor. Properly conducted, extramural clinical teaching is of advantage to the patient, the student, the attending physician, the hospital; indeed, to all concerned, and it offers a ready and practical solution of a serious difficulty which just now presents itself to the medical school.

THE MIGRATION OF STUDENTS.

The migration of students from one school to another, such as is common in the German universities, is a plan which ought to be encouraged. Such a custom enlarges the student's latitude of election, broadens his mental outlook, and the constant interchange of students strengthens and stimulates the several colleges and the individual teachers.

PRACTICAL EXAMINATIONS.

The question of thorough, practical examinations as the final test of the student's ability to enter safely on the practice of his profession, has been much neglected in America. It is a matter of great importance and must be satisfactorily solved by the university medical school, but time does not permit a fuller discussion of the matter in this address.

THE NEED OF ENDOWMENT.

The expense of carrying out the scheme which I have briefly outlined for a modern medical school is enormous. With the largest classes, and even prohibitory fees, the income from tuition must fall far, far short of meeting that cost. In a word, the cost of a modern medical education has grown to be greatly in excess of the student's ability to pay for it. State aid or private endowment must be had if these plans are to be realized. With our present outlook private beneficence holds out much the larger promise, and in the hope of such assistance there is every reason to feel the greatest encouragement. The recent gifts to medical institutions and for the promotion of medical research on a princely scale, furnish conclusive evidence of the fact that men of affairs and of large capital, whose chief desire is to find a use for their means which shall be of the largest service to the world, have come to realize that, in these medical channels, large gifts are more likely to yield a certain, speedy and bountiful return in good to the world than in almost any other. And so, in conclusion, let me assure you that the outlook is most hopeful. The modern university school is already in existence in three or four cities, and while it has not yet come to its full glory and usefulness, we may rest assured that the signs are most encouraging, and that in the near future we shall have in operation in America medical schools in advance of any which the world has yet seen.

SHOULD THE GENERAL PRACTITIONER HAVE A WORKING KNOWLEDGE OF THE OPHTHALMOSCOPE AND TRIAL LENSES?*

ALBERT RUFUS BAKER, M.D.
Professor of Ophthalmology in the Cleveland College of Physicians and Surgeons.
CLEVELAND, OHIO.

Baas says in Handerson's History of Medicine[1] that "Specialism is *per se* an evidence of a civilization of high development: indeed, of one tending toward its downfall," and speaking of the division of medical labor in our larger cities, Handerson[2] says that "the dangers of running specialism to seed are very manifest."

It might be possible to demonstrate historically that excessive specialism is the forerunner of medical decay, so that if in the present discussion I run counter to modern medical thought I may find justification for doing so in the ups and downs of medical progress throughout the ages.

There is no necessity of my calling the attention of the members of this Section to the great importance of the ophthalmoscope as an aid to diagnosis. And yet, I fear that while it is so valuable to us and we accept its findings with such confidence we often fail to impress upon the general profession its extreme importance.

One of the most impressive lessons I ever learned happened upon the receipt of Wood's little inexpensive English edition of Haab's Atlas of Ophthalmoscopy. When it was delivered at my office there were two or three general practitioners and several medical students present. I expressed myself as doubtful whether colored pictures of the fundus of any value could be published for so small a price. In order to test the accuracy of the representations it was suggested that I first examine the plates and make my diagnosis of the case represented. I was expected not only to diagnose a case of retinitis, neuritis, choroiditis, atrophy, etc., but to express an opinion as to the probable general conditions: such as syphilis, Bright's disease, brain tumor, ataxia, etc. After going through the entire list of 105 plates and checking up all my mistakes by comparing my diagnosis with the printed text with each illustration, in the words of one of the gentlemen present I only fell down on six: one of these I diagnosed as congenital, opaque nerve fibers, but as the patient was a rabbit and I failed to diagnose the rabbit it was counted against me. This test proved to my mind that the plates were extremely valuable, but to the gentlemen present it was an object lesson in the value of the ophthalmoscope which they never forgot; and I believe all of them have become enthusiastic users of the ophthalmoscope. One of them, the late Dr. Tuckerman, a man over forty years of age, used it intelligently daily in his private and hospital practice. There is something most remarkable when you come to think about it, that upon a hasty glance at a cheap reproduction of the appearance of the fundus of the eye you are able to say of this one, the patient has Bright's disease, of that one, congenital syphilis, another, pernicious anemia, another, brain tumor, and of another, probably his parents were cousins, and so on through the list. When I have presented the subject to the student in this light and then explained to him how inadequately any picture, no matter how well executed, fails to portray the eye-ground as seen by the skilled observer, I have no difficulty in kindling an enthusiasm in the mind of the student to see for himself.

But I had intended to take it for granted that we all believe that it would be a good thing if every practitioner could use the ophthalmoscope intelligently. The only question being, is it practical? Is it possible for the average medical student in the time allotted to him or that he may take profitably from his other studies to gain a working knowledge of this instrument? Twenty years ago I should have answered this question in the negative. My recollections as a student in the Moorfield Hospital in London were disheartening where many students came from America and would hang around the clinic for weeks and months and I am confident that many of them returned home without ever having seen a fundus oculi.

During my early experience as a teacher of ophthalmology I often became discouraged after failing completely to aid the student in seeing the fundus, even after many trials. But the medical student has changed. He is quite a different animal from what he was ten or twenty years ago. The student that now enters a medical school has at least learned how to study, and after two or three years of careful, thorough, conscientious laboratory work, when he comes up to the senior year he brings with him not only a trained mind but a trained eye and a trained hand. And I find that it is the exception now, when a student with this thorough laboratory training does not see the fundus the first times he takes the ophthalmoscope in his hand. He not only sees it but is able to make a creditable drawing of what he does see. Formerly, I sometimes doubted the wisdom of spending so much of the time of the student in the laboratory looking through microscopes, but I find that the training of eye and hand is just the preparation they need to become skilled diagnosticians, physicians and surgeons. And while I still doubt the value of some of the things they learn there I am fully reconciled to their spending their time in work of such exceeding great value in training their faculties for the more important work they are preparing to perform.

My experience has been that the student who buys an ophthalmoscope at the beginning of his junior year gains a practical knowledge of its use before he graduates, providing he has sufficient opportunity in dispensary and hospital clinics; and I believe at the present time most medical schools have sufficient clinical facilities for them to do so. And they do it without encroaching upon the time that should be devoted to other studies. It is surprising in our school, which I presume is no exception, how many of the clinical teachers are becoming familiar with the use of the ophthalmoscope.

---

[1] Handerson's Translation of Baas' History of Medicine, p. 17.

[2] Ibid., p. 857.

The practitioner who uses the ophthalmoscope is not usually content with his knowledge of ophthalmoscopy until he has mastered the trial case and is able to fit spectacles also. I know that the mere mention of the general practitioner fitting spectacles suggests to the minds of every one present the middle-aged or aged practitioner who, having failed to make a success of general practice, took a six weeks' post-graduate course, bought a brand-new ophthalmoscope and test case and came home prepared to teach us all how to snip muscles. The traveling optician is preferable. These men were never equipped as general practitioners; they are hangers-on, and not worthy of consideration. I have in mind the medical student as we find him to-day—the man trained in mathematics, physics, chemistry and biology before he enters on the study of medicine. The student thoroughly trained in numerous laboratories for two years supplemented by two years of clinical instruction and in most cases an additional year of hospital practice either at home or abroad. The practitioner with this training can not be judged by the standards established ten or twenty years ago.

Following the lead of Johns Hopkins nearly all the medical colleges of the country adopted the plan some years since of confining all the clinical teaching to the last two years of the curriculum. It has been found that this method has not proved as satisfactory as anticipated, and many schools are now providing clinical instructions for sophomores and freshmen as well as for more advanced students. It is the opinion of many medical teachers that it is desirable to bring the student in contact with the patient almost from the first day he enters upon the study of medicine. This, it is claimed, was one of the redeeming features of the old perceptor method of teaching. The student first saw patients with his perceptor and subsequently in the medical school received his theoretical education. The study of medicine should be a perpendicular rather than a horizontal investigation. The student should first examine the patient, follow the clinical history of the case, examine the secretions and follow the patient to the postmortem table, and then study the pathologic specimens in the laboratory, thus obtaining a complete concept of diseased conditions rather than an innumerable number of disconnected facts and observations in the biologic, chemical, anatomic, histologic, bacteriologic, physiologic, pathologic and pharmacologic laboratories. The work as now prosecuted is extremely valuable from a scientific standpoint, but being so far disconnected from the main object in view, viz., that of making good practitioners of medicine, that the student leaves the modern medical school illy-prepared to follow his vocation. It is claimed that we have effectually killed off the medical perceptor but have not supplied his place. The perceptor who used the ophthalmoscope taught his student to use it. The stethoscope, laryngoscope, ophthalmoscope and other instruments of precision in diagnosis should be put in the hands of the student the first year of his medical studies.[*]

Some years since the oculists of Ohio were summoned before the State Board of Registration and Examination to formulate a rule to govern the prescribing of spectacles by the opticians. Some of the younger ophthalmologists were very much in favor of a strict interpretation of the law, enforcing which would prevent all but graduates of medicine prescribing spectacles. I asked this question: If the opticians do not this work who will? We have over 3,000,000 people in the state, all of whom sooner or later will need spectacles. There are probably not more than 100 physicians in the state competent to prescribe spectacles intelligently. It is clearly impossible for them to fit the entire population with glasses. The general practitioners are unfitted by education, experience or inclination to do it, and until such time as they are willing to undertake this work I believe that it would be injudicious and unwise to interfere with opticians prescribing spectacles. The following rule[1] was adopted:

> *Resolved*, That the act of prescribing and adjusting glasses in uncomplicated cases of visual defects shall not be held as practicing medicine, within the meaning of the law, but that the act of prescribing glasses or of adjusting the same, without the order of a physician in any case in which the vision can not be brought up to the normal, and which, in addition to visual defects, there exists any inflammatory condition, organic change, or disease of either the constituent or auxillary structure of the eye, *shall* be held as practicing medicine, within the meaning of the law.

In my address as chairman of this Section in 1894 I expressed the opinion that every practitioner should possess an ophthalmoscope and a case of trial lenses and that he should be able to fit spectacles much better than jewelers, druggists and traveling spectacle vendors who style themselves opticians. I am of this opinion still. But until such time as the general practitioner prepares himself to do this work the spectacle vendors will continue to reap the harvest which properly belong to the medical profession. It has ever been thus—quacks abound because the profession does its work poorly. We howl about overcrowding the profession, and yet the people of this country spend millions for patent medicines and thousands for legitimate drugs on physicians' prescriptions. The hardest chair to find a man to fill in our medical colleges is that of practice of medicine, and will continue to be so until the younger members of the profession are prepared to be all-around general practitioners. It is a mistake for every young physician to hope to become a surgeon or a specialist. If I were a young man entering the profession to-day, I would make a specialty of general practice, and would prepare myself to do much of the work that the surgeon and specialist now do.

605 New England Building.

TEACHING OPHTHALMOLOGY TO UNDERGRADUATES.[*]

FRANK C. TODD, M.D.
Professor of Clinical Ophthalmology and Otology, University of Minnesota, Etc.
MINNEAPOLIS.

Vast changes have been wrought in the practice of medicine in the past quarter century and its teaching has undergone radical metamorphosis. Time forbids, and necessity does not demand, a review of this evolution.

Teaching, even to-day, is of secondary importance to the average medical teacher, practice demanding the most of his time and study, and as a consequence the whole scheme of teaching in most medical schools lacks system, and the different branches, and even different portions of a branch, are taught entirely independent of each other, no co-relation being observed. The chaos resulting from this medley is like a vaudeville. Each star and satellite performs his act, and when the final curtain rings down there is left with the spectator a sense of incompleteness, because the entire performance is devoid of plot. It is time, therefore, for us to pause in our scientific work and give some attention to this subject.

[1] Ohio State Board Medical Registration and Examination in First Report, 1896, p. 25.

[*] Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott.

This paper pertains solely to the teaching of ophthalmology to undergraduates and will be considered under two heads, i. e., method, and matter of teaching.

METHODS.

Didactic Teaching.—Many of our teachers are successful practitioners, and are able by virtue of their experience to give good clinics, and because of their practice can furnish the necessary material; but good practitioners are not always good lecturers. Lectures are of undoubted value when given by a good talker or illustrated in some manner that will enable the student to retain what he hears, as, for instance, by the introduction of cases, specimens, drawings, or use of the microscope or stereopticon.

Recitations.—The student should not be obliged to so occupy himself taking notes that he will miss much of the lecture and to avoid this we should have textbooks adapted to the student's needs from which lessons may be given. This recitation method of teaching is of extreme value, and is much neglected in the last year of the medical course. If desired, the regular lecture course can be given by one of the professors, for instance, and the recitation course by one of his assistants.

Clinical Teaching.—While it would be unwise to advocate any one method, we must agree that the most valuable way of teaching ophthalmology is by clinical instruction. Clinical lectures may be given before a full class, and a whole series of cases may be presented for illustration. In this manner the different types or stages of a disease may be exhibited or the differential diagnosis between like affections may be demonstrated. Then there is much to be gained by clinical demonstrations of the methods of examination and treatment, and these may be carried on in the dispensary before small sections. Students should have an opportunity for practice at such times. The operating clinic should be held before sections small enough so that every student will have opportunity to see the entire operation. Operating before an amphitheater full of students who can not see what is going on, is to be deprecated. Major operations, such as cataract extraction, even if the student never intends to perform them are of value, as they teach by object-lesson how to prepare a patient preliminary to operation, the technic of intra-ocular surgery, the objects, danger, results, etc., of such operations. The minor operations, such as the extirpation of chalazia, the opening of lachrymal abscesses, etc., are valuable because the student will probably sooner or later perform them himself.

Laboratory Work.—In histology, bacteriology, pathology, anatomy and physiology, laboratory methods should be taught the student before he takes up the subject of ophthalmology *per se*, by the teachers of those branches.

MATTER.

With the development of the science of medicine and surgery and the advent of bacteriology, laboratory teaching in chemistry, anatomy, histology, physiology and pathology now necessarily occupy more time than was required fifteen years ago to finish the entire medical course. In addition to this laboratory work and the subjects which were taught at that time there are many additional chairs, not to mention such courses as mechanotherapy, history of medicine, hygiene, sanitation, etc. All of the branches, including the original fundamental subjects of practice, surgery, and obstetrics, and the various specialties, have enlarged their scope, demanding more time for their teaching. Clinical teaching, in the meantime, has been increased to a great degree, and consequently we find each day more filled in the medical curriculum, now, when a medical course in a high-grade college consists of four years of eight months each, than when only two years of six months were required.

If you will study the schedules of the various leading medical colleges you will be surprised to find every day so full. You will find in the senior class that about thirty hours per week are required; that in many colleges a senior student is carrying from 16 to 20 branches at one time, and you will be able to realize how little time remains for study and digestion of the knowledge he is trying to gain. It becomes necessary, therefore, in preparing the course of study to concentrate and eliminate.

Concentration.—By this is meant the concentration of a branch within a shorter period, completing ophthalmology and otology, for instance, in eight weeks by having four hours a week instead of spreading them over thirty-two weeks of one hour a week. Concentration may be so arranged that the student will carry at one time only one-quarter the number of studies now required in many medical colleges. It enables him to remember from one lecture to another, and prevents confusion that is bound to exist when he is burdened with many branches at one time.

Elimination.—By elimination is meant the elimination of unimportant branches and irrelevant portions of important branches. This matter of deciding what should be eliminated is a difficult one. In earlier days the special branches were taught by the general practitioner and no attempt was made to teach details which the general practitioner will never have occasion to use in his practice, or if he does have use for them he will have forgotten them long before that time arrives, while he can easily post himself when the necessity arises.

There is a vast difference of opinion among teachers of the same subject as to how much should be required. By studying the various college catalogues, we find in ophthalmology and otology, that in one university there is no didactic teaching and only 52 hours of clinical teaching while in another 56 hours of didactic and 64 hours of clinical work are required of each student, and there is as much more optional clinical work. It seems, therefore, that the ophthalmologist is not the one to fully decide how much time should be allotted to ophthalmology, but that the whole faculty should coöperate in outlining the general course of study, apportioning the time as seems best.

Some teachers in ophthalmology believe that we should teach in detail not only all of the diseases of the eye, but ophthalmoscopy, refraction, unimportant operations on the eye, retinoscopy, the theories of color perception and what not, but where they find the time in the medical curriculum to give them this knowledge is difficult to understand. A proper preparation for refraction work alone requires an entire year of continuous study and experience, and a superficial knowledge, such as could be gained in the time at the undergraduate's disposal, is worse than none at all. I believe there are certain portions of ophthalmology (and this is true of every special branch) which are essential to the general practitioner, especially if he is located in the country; for instance, the knowledge of how to differentiate glaucoma from iritis, because each of these affections requires immediate attention, and the treatment of these two diseases being opposite, a mistake might prove fatal to sight. He should be taught also how to attend to those things which he will meet commonly in his practice, even though they are not of a serious character. Not only should these things be taught, but the student should be required to learn them, and if he fails to pass a satisfactory examination he should not be allowed to graduate, for he would not be a safe practitioner. He should be taught the things he can do with safety and what things are dangerous in unskilled hands, for "fools rush in, where angels fear to tread," and many eyes and lives are sacrificed as a result of the ignorance and assurance of those who do not know their limitations.

In this process of elimination, then, we must require only as much time in the teaching of ophthalmology as will give the student a practical knowledge of those diseases and conditions which are the most common and the most important. Preliminary to the regular course on the eye from the teachers in those branches, he should gain a practical knowledge of anatomy, physiology, histology, pathology, and bacteriology, so that very little time need be occupied during the regular course in ophthalmology upon these subjects. *In the regular course in ophthalmology he should* be shown how to examine the eyes by inspection, how to evert lids, oblique illumination, the technic of ophthalmoscopy and be shown a normal fundus, the inspection of the cornea for foreign bodies, method of removing, the diagnosis of ulcers and other corneal diseases, the pupil, its changes in health and disease and in chloroform anesthesia, palpation for tension and ciliary tenderness, how to test and record the acuteness of vision. The common diseases of the eye, such as blepharitis marginalis, hordeolum, chalazion, dacryocystitis, simple conjunctivitis, trachoma, purulent conjunctivitis, phlyctenular conjunctivitis, keratitis (parenchymatous and ulcerative), iritis, sympathetic ophthalmia, panophthalmitis, glaucoma, injuries. Besides these, other diseases and conditions should be defined and causes given, such as trichiasis, entropion, ectropion, ptosis, orbital cellulitis, pterygium, staphyloma, scleritis, cyclitis, choroiditis, retinitis, intra-ocular tumors, cataracts, optic neuritis and atrophy, amblyopia. Under refraction the symptoms which result from errors of refraction should be fully explained and the ordinary terms defined.

Elective and Optional Courses.—These may be given to supplement the required courses, which will cover as fully as the time allotted will allow those less important portions. In order to avoid possible confusion I will define the words elective and optional, and I can best do this by quoting Professor Dodson of Chicago University:

> Election may be defined as that method under which the student pursuing a certain course looking to the acquisition of degree or diploma, is allowed some choice in the courses of study which he may take. The term "election" is not applied to those studies which are taken by special students, who enter the college with no intent of completing the course and receiving the degree. It is convenient, furthermore, to distinguish between elective and what may be called "optional" courses, an optional course being defined as one which a student may take in addition to his regular work, and for which no credit is given, excepting perhaps a special certificate setting forth the fact that the student has taken the said optional course.
>
> To the teacher the elective system presents the advantage of the greatest possible incentive to good work. An instructor whose students are required to be in attendance upon his lectures, whether they would or no, is under no obligation to make his course the best possible and he is prone to become careless and indifferent in his teaching. If, on the other hand, the attendance upon his classes is left to the choice of the student, who is at liberty to elect other similar courses taught by other teachers in the faculty, the attendance will depend solely upon his efficiency as a teacher, and constitutes a continual and most powerful inducement to the best work.
>
> It is, however, the testimony of all who have had to do with the elective system that the greatest benefit which results, therefore, is the difference in the spirit which animates both student and teacher. It is wonderful, indeed, to observe the difference in the interest, the enthusiasm, and the energy with which a student will pursue a course of study which he himself has chosen, in contrast to that which he has been compelled to take.

CONCLUSION.

In conclusion, I desire to request a free and frank discussion of this important subject, which my paper has presented in only a superficial manner. While there is no doubt that too little attention was formerly paid to the specialties, I believe that we are going to the other extreme and trying to teach too much. We are giving too much detail, and are wasting valuable time in the attempt to cover the entire subject with all the theories and varieties of diseases that to us as specialists seem important. Neurologists, dermatologists, ophthalmologists, and other ologists who work along specific lines are apt to become narrow and overestimate the importance of their particular branch, and to forget that there are other branches more essential in fitting a man for practice. We must bear in mind that we are educating our students to become general practitioners, and it is not within the scope of the undergraduate medical college to make specialists of them. If we occupy more of their precious time than is necessary to teach them only those things which are essential to their general practice we are stealing time which should be devoted to the more important fundamental branches.

DISCUSSION

ON THE PAPERS OF DRS. BAKER AND TODD.

Dr. Swan M. Burnett, Washington, D. C.—The proper consideration of this proposition implies a definition of several terms, and the answers to some collateral questions.

In the first place, what are we to understand by the term "general practitioner"? Ordinarily, we mean the man who gives his attention to internal medicine alone, to the exclusion of the well-recognized specialties, in which case he should be considered quite as much of a specialist as the ophthalmologist or gynecologist; or, we may mean the man of whom the country doctor, or the members of the medical branches of the army and navy are the types, who are expected to combat all human ills from toothache to those diseases demanding an abdominal section or the ligation of the large arteries.

Evidently, the needs of each of these extremes of general practice, as regards the use of the ophthalmoscope and test lenses, must be widely different.

Then, again, what are we to understand by a "working knowledge"? Is it meant mere ability to illuminate the fundus by the ophthalmoscope, or the power to elect any changes, however minute, from the normal; or, in the case of test lenses, the capacity to do more than establish the existence of hypermetropia or myopia, or possibly the presence of astigmatism?

As a necessary corollary to these questions, arises the equally important one, how much pertaining to these subjects shall be taught to the undergraduates in our medical colleges?

To state, categorically, my own opinion, formed after a by no means inconsiderable thought and observation, I believe that, barring the very exceptional cases, the less the general practitioner of any kind has to do with a practical working of the ophthalmoscope the better, and for the following reasons:

First, ophthalmoscopy is an art, and an art for the average man by no means easy to learn, and, moreover, an art which requires constant practice and a large experience to bring to such a state of efficiency as to enable it to be of certain benefit to the man who employs it. Here as elsewhere, "a little knowledge is a dangerous thing," for it is just those cases where it would be of most service to the general practitioner that require that expertness without which confusion is sometimes worse than confounded and absolute harm may come through a false diagnosis. The ophthalmoscope to be of any real value to the practitioner must be used by an expert. Such an expert is to be found around the corner in even our small towns now, where eye specialists abound. I have never yet seen a general practitioner whose ophthalmoscopic knowledge was likely to be of any benefit to himself or to his patients. There are, of course, exceptional cases where this broad rule does not apply. A clever and enterprising general practitioner may take up ophthalmoscopy as a fad, just as he would go into stamp collecting, or painting in water colors, or for the purpose of impressing his patients with his wide attainments, but like fads in general, it will not redound in the end to the permanent good of anybody.

Of all the general practitioners it would seem that the members of the medical corps of the Army, Navy and Marine-Hospital Service, who are often far removed from expert skill, and have to depend upon themselves alone, would be required to possess such a "working knowledge" as we are now discussing—and, as a matter of fact, it is announced as one of the requirements for admission to these services. But, I find after inquiry that it is practically a dead letter, and that while a knowledge of the working of the ophthalmoscope is placed to the credit of the candidate, in the same way as the knowledge of another language would be, an actual test is seldom or never made, and mainly for the reason that the examiners themselves, as a rule—and I place it to their credit —do not deem themselves competent to conduct such an examination. It should be stated in this connection, however, that Surgeon-General Sternberg informs me that in the Army Medical School, which he has established in Washington, the use of the ophthalmoscope is now practically taught to the young medical officers.

That an expert familiarity with the ophthalmoscope might at times be of value to the country doctor is also to be admitted, but here again, unless this knowledge be thorough, it is much more likely to lead him into trouble than out of it. All of us remember the marvelous and unique pathologic conditions of the fundus we were constantly running up against, particularly congestion of the retina, in our callow days of ophthalmoscopy. Of all the methods of physical diagnosis, that of ophthalmoscopy requires most skill and the largest amount of experience to make it at all serviceable to the examiner, and such skill and experience the general practitioner can never, from the nature of the circumstances, have. It follows as a necessary corollary, if the position I have taken is a tenable one, that we should not demand that the average undergraduate should waste his time in attempting to acquire a "working knowledge" of an instrument he will never use. When we shall have established, as we must in time, the elective system in our medical curriculum, then those who elect to take an ophthalmoscopic course should be thoroughly instructed in the use of the instrument, and for this purpose one hour a day, for three months at the very least, should be given to each student. Most students will require twice that length of time, and some even more, before they can command such a skill in the manipulation of the instrument as to give them confidence in its use. The time given to the useless and unfruitful effort to give the average undergraduate a "working knowledge" of the ophthalmoscope would be much better spent in acquainting him with the external diseases of the eye and particularly the diagnostic signs of iritis, conjunctivitis, glaucoma and the various forms of keratitis.

It goes without saying, of course, that the principles of ophthalmoscopy should be taught as a part of physiologic optics, as forming an essential portion of that general and fundamental knowledge of the functions of the human economy that is necessary for a complete medical education such as we propose to furnish.

It is well, in my opinion, for a general practitioner, particularly when removed from a competent specialist, to be able to test visual acuteness and to determine by means of test lenses the probable existence of myopia or hypermetropia and possibly astigmatism. Anything more refined than this should not, as a rule, be attempted, though the ability to test the refraction of the eye and determine the muscular imbalance carefully would be of infinitely more value to him in the diagnosis and treatment of the cases that he has most to deal with, particularly headaches and obscure nervous symptoms, than the ability to use the ophthalmoscope even with skill.

Dr. Casey Wood, Chicago—Most of us are guided in the opinion we form as to the advisability of teaching ophthalmoscopy to general students of medicine by the number we have to deal with. Those of us who have large classes appreciate the difficulties more than those who are not called on to instruct such large numbers. I may be pardoned for telling you something of the methods employed in the University of Illinois, because I believe they have a direct bearing upon the whole question.

After serious consideration of the subject, and after conferences between the professors of ophthalmology and their assistants we decided on this plan: that one man should give the "didactic" lectures in such a manner as to make his teaching plain not merely to those close to him, but to those who are, perhaps, forty feet away. To this end lectures are profusely illustrated by large charts, the stereopticon and the projection apparatus, and though that has not been, perhaps, quite satisfactory in teaching certain portions of the subject to a class of over 200, yet it has, I think, answered fairly well. With the projection apparatus, for example, one can throw a picture 14 feet square on a sheet, which can, of course, be seen in detail by men at a considerable distance from the lecturer.

Operating before a large class we have abandoned, because we have found it in every way unsatisfactory; the earnest teacher does not wish to feel that he is a party to such waste of time. To do a cataract extraction before a class of two hundred men, for example, benefits nobody except a few students on the front row of seats. It is much the same with the exhibition of patients; only those cases that exhibit signs of disease visible to students on the distant seats are shown. Thus we dispose of the didactic part of the teaching. For complementary studies the large senior class is divided into small sections so that patients with the commoner diseases of the eye can be successfully exhibited to them. Pretty much the same thing is again demonstrated in the dispensary. We insist upon it, also, on all occasions, that the eye signs of disease are as necessary for the general student as the heart and lung sounds. Why should the undergraduates avoid a study of the eye signs of disease? Yet that is just what in the past they have done. To arrive at a proper diagnosis they learn all the other symptoms of disease, but decline to investigate disease from the standpoint of the eye symptoms and we insist upon it that these are as important for this purpose as any other clinical evidence.

In the third place we have endeavored to teach students not merely the diagnosis and treatment of the commoner diseases of the eye, but the differences between eye diseases that are serious and those that are simple. We started out by having a program printed, a copy of which is given to each student, who is told that he will be expected to pass an examination upon these headings, and we do not deviate from it. We have not succeeded nor have we attempted to make good ophthalmoscopists of our students even in this way; I do not think it is possible, for example, in the time at our disposal, to teach the undergraduate the use of the ophthalmoscope so that he can diagnose any except gross lesions of the fundus with any certainty. Perhaps it is possible to teach the ordinary student to diagnose such a fundus change as a marked case of optic neuritis, or, he may learn to see the fundus or to make some use the trial case, but I protest against the attempt to teach him that complex branch known as "refraction." I would rather have the patient go to an ordinary optician than have the average medical graduate work out a case of refraction. This contingency it is not necessary, I think, to meet in the West where almost every small town has a competent ophthalmologist. I do not believe in the danger suggested by Dr. Baker, that the people of this country will be neglected because of lack of ophthalmologists to look after their eyes.

Another experiment we have been trying is somewhat opposed to that entered on in other universities. The latter insist on the men having an academic training for the first two or this four years, obtaining their instruction in the university itself. They are not allowed to look at sick men and women, but give up their entire time to the elements of medicine and surgery. We have taken an opposite view of the matter and give clinics to freshmen and sophomores, in imitation of the good old days when the student went around with his preceptor. It is certainly popular with the men themselves and so far has succeeded very well indeed. We give these junior students much the same work we give the seniors. The printed program just alluded to is closely followed and if at the end of the session students can not diagnose a case of iritis, detect one of glaucoma and recognize the ordinary external diseases of the eye, then the man engaged in the teaching has fallen far short of the scheme so mapped out.

Dr. W. H. Wilder, Chicago—This is a subject that has interested me greatly for a number of years as it has happened that I have had something to do with the scheme now in vogue in Rush Medical College.

I am heartily in accord with the views of Dr. Baker, that the general practitioner should know something of ophthalmology, and can not agree with Dr. Burnett, that the less he knows of the ophthalmoscope the better.

I can give you more clearly my views by telling you the character of work done in the Rush Medical College—which is the medical branch of the University of Chicago. In the first place, our students pursue the first two years in the university proper, in the biologic laboratory, and when they come to us they are prepared to apply the theoretical, scientific knowledge which they are supposed to have obtained in the university itself. The elective system has been in operation for a number of years. While a man can elect a certain course, he is required not to elect too many of the same kind at one time. He can elect a course in ophthalmology if he will, but can not omit such important things as obstetrics or surgery. He is marked in each subject according to the number of hours he takes. We find the method very satisfactory because there is a spirit existing between instructor and student that formerly did not exist when these studies were required. He is allowed to elect ophthalmology as one of his senior studies and we advise him to pursue the following course: first a course in the fundamental principles of ophthalmology; then a course in use of the ophthalmoscope, and finally he is put in the clinic, because not until then has he the tools with which to work. In his earlier clinical work we give him cases that illustrate normal conditions. He gets a course of didactic lectures, or rather recitations, in a limited class; following that a course in the use of the ophthalmoscope, and not until he has had these two courses does he engage in clinical work. We believe that a small class is essential, never exceeding ten, and that, of course, requires a large number of teachers. Our clinical classes in the eye and ear infirmary are limited to ten men and they can get as close to the operator as the assistant who is helping and in this way we can give them practical instruction. A man can watch the case through the whole course. He is never allowed to do clinical work until he has learned the method of examination of patients. He is not judged by his ability to make a diagnosis so much as by his ability to observe a case properly and bring out the salient points. If he has acquired correct methods of observation he deserves more credit than when he steps up to a case and makes a "snap-shot" diagnosis. We teach our undergraduates something of the use of the ophthalmoscope. We keep tabulated lists of cases scattered around town and we sometimes pay them a little to keep them coming to us just as they do in the clinics of Vienna and Berlin. The student is told how to use the ophthalmoscope and is required to make a drawing of the interior of the eye, just as he is required in the histologic laboratory to make a drawing of the section under the microscope. In this way the examiner can tell whether the man really sees what he says he does.

I think from the examination of the students that they do learn something about it. Of course, they can not become experts, but they can recognize promptly a normal or abnormal disc and have sufficient knowledge to enable them to know whether blindness is due to opacity of the media or to gross lesions of the fundus.

Dr. Edward Jackson, Denver—I think the discussion of Dr. Burnett on the teaching of ophthalmoscopy to medical students in general should not go without some additional remarks. I want especially to call attention to the value of ophthalmoscopy as a branch of general education for the medical man. There have been several very noteworthy instances of its cultivation by other than ophthalmologists—Hutchinson, Hughlings, Jackson, Gowers and others whose training in ophthalmoscopy aided them in becoming eminent in other fields; and who have spoken with strong emphasis of the value of that training in their subsequent careers. It is not only the value of using the ophthalmoscope, but the general training of the work of exact observation. We are trying to raise the requirements of the medical course and encouraging the development of laboratory courses, and it seems to me that in this connection the ophthalmoscope has been very greatly neglected.

Admit, for the sake of argument, that very few medical students learn to use the instrument so as to make a diagnosis of brain tumor or Bright's disease; the same thing is true with reference to the microscope. The ophthalmoscope is a microscope, a low-power microscope, the kind that is of the greatest value to the student, and it is a microscope used on living tissue. I think that the teaching of ophthalmoscopy as a branch of general medical training is not sufficiently appreciated even by ophthalmologists themselves; and I should regret to see this discussion go out without some expression of an appreciation of that value.

Dr. George F. Suker, Chicago—I think it has been the experience of most of us who teach that unless the student can see a cataract operation, or some major operation, he does not take very much interest in the subject. I think it is absolutely essential the way the curricula of our colleges stand now, that every student who is graduated should be able to describe the normal fundus, if nothing else. And, I make it my aim to pay particular attention to the normal fundus rather than to diseased conditions. The medical student does not and can not appreciate the dainty pathologic fundus lesions unless he fully knows the appearance of the normal fundus. If we can impress on their minds that in so many general diseases it is necessary to make an ophthalmologic examination so as to fully understand the case in hand we will not have labored in vain. But, in order to imbue the student with the importance of ophthalmoscopy it is the duty of the teachers in the various other branches to call especial attention to such diseases as have ocular lesions.

If the student is able to fully recognize the variety of normal fundi, he then can recognize an abnormality and if we achieve this in our teaching, why, a great deal will have been accomplished. In order to accomplish anything along the line of ophthalmoscopy, we should endeavor to give individual irstruction to our students and not, as is often done promiscuously, turn a score of them loose on a patient in the dark room without sufficient guidance.

Dr. Leartus Connor, Detroit—The principles of educating a student should be scientific and if scientific each part would be symmetrically related to every other as in a surgical operation and there would be one thought running through the whole thing. Applying this to teaching as we generally find it you will observe that there is much to be desired. Students should have this training if for nothing else than to let them see that there is something that is absolutely certain in medicine and absolutely certain in their work. It lets them see that somewhere there is a rock on which to stand. There is so much of uncertainty in medicine that it is too bad to prevent the attaining of what is definite. The teacher in each branch should be able to present the eye features of his own subjects, and so the student can see these in normal relations. I do not think as a Section we can lay down any dictum. It remains for the teachers of each college for itself to get together and determine what can be left out and what must be put in. I am impressed with the belief that the time is not far distant when we will have such a scientific arrangement of teaching as we do in the best surgical operations and that it will be just as satisfactory. I am glad this subject has come up for our consideration, not that we can settle it, but that we can have some influence in promoting a correct solution of the problem.

Dr. Herman Knapp, New York—Whenever a new department is added to the curriculum and the final examination of the student there is a howl, and so it has been with ophthalmoscopy. At the University of Columbia (N. Y.) there was no question asked in ophthalmology until fourteen years ago, when, after Dr. Agnew's death, I made it the condition of my acceptance of the professorship that ophthalmology should be a recognized branch in the curriculum, that the professor should be paid, that he should examine the students and give the markings in his branch at the graduation. The immediate consequence was that the same rights were accorded to the other so called clinical professors. Now our students have didactic demonstrative lectures in the college and clinics, in sections in the hospital and are trained in functional examination of the eye and in the use of the ophthalmoscope, the drill courses, in sections are obligatory, and the student has to hand in his certificate of attendance when he presents himself for his final examination.

Dr. Burnett said 'a little knowledge is a dangerous thing," but who of us can say that he knows all? Our knowledge is all relative and there is nothing of which we know enough. We have to learn what best we can and even the little we have learned is frequently very useful—of which ophthalmoscopy gives plain testimony. I do not think any retrograde movement should be encouraged. Our college course has been lengthened and probably will still more be lengthened, until the time and facilities are sufficient for the average student to acquire by scientific study and methodical training, practical knowledge to diagnose and treat all the patients that will come before him.

Dr. Crumb, Utica, N. Y.—I think it is of decided advantage for every student to have a practical training in ophthalmoscopy. It is of advantage to the physician as well as to his patients, and also to the oculist, for if a man has had any training in ophthalmoscopy he soon learns to appreciate the difficulties in being skilled in its use and it gives him more respect for those who are expert and he will not be so apt to send his cases to the optician. We have instances in our city where good members of the American Medical Association send their cases to the optician for refraction, which is certainly decidedly wrong and the younger members of the profession, who have some knowledge of ophthalmoscopy, do not do it.

Dr. Carmalt, New Haven—I really think this discussion belongs to some other Section than ours. We are all well enough convinced that ophthalmology should be taught in the general course and I agree with all that has been said in regard to its importance. Certainly, any general practitioner who attempts to do anything with nervous and various constitutional diseases must use the ophthalmoscope constantly and ophthalmology should have just as important a place in the curriculum of study as surgery and medicine. It is a part of these general branches. In the Yale Medical School we have examinations, and the students must attain their marks which stand in the same relation as any of the other special branches. I think it belongs to other sections to speak of its importance. We have no doubt about it.

Dr. F. W. Higgins, Cortland, N. Y.—There is quite a large class of specialists in our Section who think that the less the general practitioner knows of the ophthalmoscope, the better. I can only speak on the question from the point of personal experience. Like some of the others here I first learned the use of the ophthalmoscope in my own office. We were general practitioners not satisfied with the knowledge given us by our schools. Lately much good work has been done in microscopic examination of the blood, but none of us who were graduated a few years ago were instructed in the technic. If we wish to keep up with the most improved methods of diagnosis we must do so in our own offices by grinding out the subject for ourselves. That is what I did with the ophthalmoscope. I have had two assistants in my office that I had no trouble at all in teaching to use the ophthalmoscope. It is easier than teaching them to use the microscope. To begin with, the dilated pupil is the whole secret. If we do that in fifteen minutes we can teach a student to see the fundus. I think we should do a little missionary work among the general practitioners. There is no danger that they will all become oculists. It is true that many physicians do not know how to use a microscope, but it seems to me that no doctor should be satisfied who does not own and use a microscope and an ophthalmoscope.

Dr. Frank Allport, Chicago—In my own teachings I have purchased some twenty five papier mache eyes and before my students undertake to look into the human eye they go into the dark room with a row of these eyes, each student with his own ophthalmoscope, and they work on these until they are quite capable of examining the human eye with dilated pupil.

Dr. A. R. Baker, Cleveland—About all I want to say has been said and I only add that if, as Dr. Knapp has stated, it must be a dull student, indeed, that can not see the fundus in five minutes it is scarcely necessary to waste time on the papier mache eyes. Because all of us do not become expert with the stethoscope is no reason why it should not be taught. It devolves upon us to educate the general practitioner in this matter. I was taught as a student that I should not attempt to learn the use of the ophthalmoscope, but that I should always send all eye cases to the specialist, and I am afraid there is a tendency to that kind of teaching to day. We should try to get away from that idea. The subject can not be taught in large classes, the classes should be composed of from three to five, at the most. If you try to teach twenty or forty, you will always fail.

Dr. F. C. Todd, Minneapolis—The discussion has turned to the teaching of ophthalmoscopy to undergraduates, and while, as I said in my paper, I believe that a certain amount of ophthalmoscopy should be taught, it is a question how much should be required. It has been stated by some who have taken part in the discussion that they require undergraduates to learn ophthalmoscopy thoroughly. Where have these students gone who have been taught ophthalmoscopy? I rarely ever see a general practitioner, even among the younger men, who knows anything about the use of the ophthalmoscope. I hope they will come along later.

It is evident from this discussion that there is a vast difference of opinion as to the things that should be taught and the methods that should be used, but evolution in teaching medicine is going on and we seem to be following the example of teachers in academic work who make a study of pedagogy. We have adopted the graded system of instruction following their example and many of the medical schools are adopting the elective system, which has been so long in use in university education. If we are to teach ophthalmoscopy thoroughly it must be made an elective, for there is not enough time to teach anything more than the rudiments in the required course.

Dr. Swan M. Burnett, Washington—I only want to say a word more and that is to make a plea for honesty in our teaching. We claim to teach our students to use the ophthalmoscope and we do not do it. They do not, as a rule, know any more practically about it when they go out of our schools than when they come in. The proper teaching of ophthalmoscopy, I assert, can only be done under the elective system. You can not teach it in any practical way in less than six months. There is not a general practitioner that I have seen, nor a recent graduate, to whom the instrument is anything more than a toy. I simply want us to do rightly what we claim to do, or not attempt it at all.

PSYCHOLOGY OF HABIT IN SURGICAL TECHNIC.

R. C. COFFEY, M.D.
Surgeon to and Medical Director of the North Pacific Sanatorium; Surgeon Northern Pacific Railroad.
PORTLAND, ORE.

Medical writers agree as to the necessity for a good technic, but have been singularly silent as to how to acquire it. Too much is taken for granted. Too little study has been given to detail. No effort has been made to separate the things which are always done by habit, from those which must always be done by thought and reason. Much of this is due to a lack of understanding concerning the psychology of habit.

By far the greater part of our work is done without a thought of how it is done. Rarely can a man correctly state the moves he uses to dress himself, to cleanse his hands or to prepare a field for operation. It is much like giving a good definition for such familiar terms as "climate," "a cold," etc. Many, however, can tell exactly how to tie the latest fancy bow tie. Many can give Dr. ——'s method of sterilizing his hands; Dr. Kelly's method of catheterizing the ureter; can define karyokinesis accurately or describe fully the features of bubonic plague.

The question arises: Why do we understand difficult matters and show an utter lack of understanding of the details of simpler matters?

In the first group of examples the lessons were learned before we began to apply reasoning power to an act. At this time we acted by instinct and gradually drifted into the ways of nature. As soon as we learned an act it was turned over to the custody of our master, habit, which we may say never changes and never allows an investigation.

The cases or acts of the second group are more difficult. They come to us by hearsay; necessarily require analysis, and their infrequency or our lack of familiarity with them has prevented us from turning them over to the custody of habit. It is probable that few surgeons can recall the time when they have studiously applied their minds to the performing of every detail of a surgical operation. The fact is that we can not be positive after we have done an operation whether we have observed every point in technic, but we are willing to risk our habits to carry us through safely. We unconsciously rely on the subconscious mind to tell our objective mind if our muscles do something wrong.

DEFINITION OF HABIT.

We speak of certain acts as being nothing more than habit; but do we fully understand what we mean by the word habit? James says: "The most complex habits are nothing but concatenated discharges, due to the presence there of a system of reflex paths, so organized as to wake each other up successively, the impression produced by one muscular contraction serving as a stimulus to provoke the next, until the final impression inhibits the process and closes the chain." James further states: "In action grown habitual, which instigates each new muscular contraction to take place in its appointed order, is not a thought or a perception, but the sensation occasioned by muscular contraction just finished. A *strictly voluntary action has to be guided by an idea,* perception and volition through its whole course. In a habitual action mere sensation is a sufficient guide, and the upper region of the brain and mind are set comparatively free. In habitual actions the only impulse which the centers of idea or perception need send down is the initial impulse, the command to start."

He further illustrates this point by comparing the formation of habit to water, which "In flowing hollows out for itself a channel, which grows broader and deeper, and after having ceased to flow, it resumes, when it flows again, the path assumed by itself before. Just so the impressions of outer objects fashion for themselves in the nervous system more and more appropriate paths, and these vital phenomena recur, under similar excitements from without, when they have been interrupted a certain time."

The psychology of habit may be very aptly likened to a phonograph or kinetoscope, which reproduces the voice in the one case or a moving image in another thousands of times exactly alike, due to a very delicate impression or path made on a plate by a sound in the one case and an image in the other. This little path or impression is very delicate, and yet so accurate that when the little machine is set to work the exact modulations of the voice are produced in the one case and the exact movements of the body reproduced in the other.

The spinal centers controlling the muscles are even more accurate than these little machines, unless their delicate structures are marred by having conflicting impressions which blur them and produce many uncertain paths, causing the muscles under control of these centers to act in uncertain ways. The muscles under control of the spinal centers can be taught to act automatically with as much accuracy as the little instruments mentioned, if they are rigidly trained to a certain act by the thinking mind for a sufficient number of times; but if a number of methods are being taught alternately the impressions made on the centers would be like a phonographic plate which carries the impression made by two different songs or speeches.

NATURE OF HABIT.

In discussing the nature of habit Dumont says: "By habit a violin used by a master for a number of years acquires beautiful tones because the fibers of the wood at last contract habits of vibration conformed to harmonic relations."

James, in another place in illustrating the power of habit, refers to the case of Rip Van Winkle in Joseph Jefferson's play, who always excuses himself for every time he is drunk by saying, "I won't count this time." James says: "Well, he may not count it, and a kind heaven may not count it, but it is being counted none the less; down among his nerve cells and fibers, the molecules are counting it, registering and storing it up to be used against him when the next temptation comes."

RESULTS OF HABIT.

The results of habit as given by James are: "First, it simplifies the movements required to achieve a given result, and makes them more accurate and diminishes fatigue. The second result of habit is that it diminishes the constant attention with which our acts are performed."

Dr. Maudsley says: "If an action became no easier after being done several times: if the careful direction of consciousness were necessary to its accomplishment on each occasion, it is evident that the whole activity of a lifetime might be confined to one or two deeds—that no progress could take place in development. A man might be occupied all day in dressing and undressing himself; the attitude of his body would absorb all his attention and energy; the washing of his hands or the fastening of a button would be as difficult on each occasion as to the child on its first trial, and he would, furthermore, be completely exhausted by his exertions. Think of the pains necessary to teach the child to stand, of the many efforts it must make, and of the ease with which it at last stands, unconscious of any effort."

Carpenter says: "Our nervous system grows to the modes in which it has been exercised." James thinks "The hell endured hereafter, of which theology tells us, is no worse than the hell we make for ourselves in this world by habitually fashioning our characters in the wrong way." James also states: "Already at the age of 25 you see the professional mannerism settling down on the young commercial traveler, on the young counselor-at-law, and on the young doctor. You see the little lines of cleavage running through the character, the tricks of thought, the prejudices, the ways of the shop; in a word, the way in which a man can by-and-by no more escape than his coat-sleeve can suddenly fall into a new set of folds. On the whole, it is best he should not escape. It is well for the world that in the most of us by the age of 30 the character has set like plaster and will never soften again." So we see the habit is both our master and slave. It controls our most essential acts and yet performs practically all the menial services of ordinary life.

APPLICATION TO SURGICAL TECHNIC.

In applying this matter of psychology of habit to surgical technic the chief point is that neither the surgeon, his assistants nor his nurses can devote the mind to every little detail which is performed. The mind must be applied to the points of work which require judgment and the higher sense of reason; the details must be left to what is known as muscle sense, or spinal sense, or habit. If these actions are to be performed by the muscles, these muscles or spinal centers must be educated, and as they are not possessed with the power of reason they will act like the parrot—only as they are taught. Therefore, the principal point in arriving at a good surgical technic is education of the muscle sense.

If the parrot is to be taught to say prayers only it must never be left where it can hear profanity. If the muscles are to be taught correct methods in surgical technic they must never be permitted to act in an incorrect manner.

It is a very serious matter, during the course of an operation, if a nurse or an assistant, or the surgeon himself, becomes so engrossed with some difficult problem which comes up that he entirely loses himself so that instead of doing the right thing in the way of technic his muscles perform some old method learned years before which has proven disastrous on many occasions and which he has tried in vain to forget. An important point for us to consider, therefore, is the early education of our muscles, in one good way, so that when storms arise and when troubles come the chances are many to one that they will do right.

PATHS OF HABIT.

The paths of habit in the nervous system are all so delicate and so accurate that such a small point as having had our attention called away from our work while washing our hands early in our career may be the beginning of a habit which from that time on has caused us to neglect some little point of the surface of our hands. It may be only one corner of a certain finger nail, or a very small area in the space between two fingers, but we may rest assured that under ordinary circumstances we will neglect this space with as much certainty as that a seed will reproduce its kind, and this may be the cause of the fatal cases of sepsis for which you could in no way account.

I have no patience with the old excuse that "sepsis will occur without apparent cause in the practice of the very best men." When we have sepsis in a clean wound we may know some one has infected the patient. It may be the surgeon, his assistant or his nurse, but some one is at fault, and I think the primary blame must rest on the surgeon himself, for he must be responsible for the training of his assistants and nurses. This applies, not only to the cleansing of the hands, but to every point connected with surgical cases.

HOW TO ACQUIRE GOOD HABITS.

It is a fact that it is almost impossible for one to change his technic after he has operated for a number of years; if he has not already acquired a fairly good technic his patient will suffer because of his methods.

If he has acquired a good technic it is not his own acts that he fears, but the acts of his assistants and nurses. The question then is, how can he most quickly and most effectually train his nurses or students so that they will perform their duties in a correct manner at all times and under all circumstances?

I know of no rules better than a modification of the principles laid down by James. First, take care to launch your students with as strong and decided initiative as possible by teaching them the importance and value of habit, and that they must depend largely on habit for results. Second, never allow an exception to pass with impunity until the new habit is successfully rooted. After a number of months' practice in the same groove the nervous system will act infallibly right.

Almost nothing has been written in the form of a text on this subject. Nurses and doctors have each learned their particular method, not seeing any two persons with exactly the same technic. Their teachers have not seen fit to call their attention to the small details, or have not noticed all this. The consequence is that a wrong habit has been fixed. For instance, a physician has acquired the habit of washing his hands for five minutes. If you watch him you may notice that four minutes of this has been spent in rubbing the ends of his fingers to and fro along the brush, one-half minute has been spent in scrubbing the palms of the hands, one-third has been spent in making an occasional excursion over his hands, and one-twelfth of a minute has been spent in making an occasional tour over the hands and arms, while the spaces between his fingers have received very little attention. Another operator may reverse this order and devote a great deal of time to some point which has not been mentioned, but in not a single instance has he given a thought to what he is doing or whether all the points of the surface of his hands have been cleansed.

A nurse in preparing for a gynecological operation may first scrub everything from the tip of the coccyx to the pubes into one mass, and then begin by infecting the entire field. The brush is dipped back into the pan of water and soap, is plunged into the vagina, is again brought out and scrubbed over the external genitals, again into the vagina, and so on in rotation, infecting the entire field. In consequence the field has not received the best opportunity for being cleansed and still a much longer time is required than if the work had been done in a systematic manner.

In expressing my ideas and the method of instilling habits into the nervous system of pupils I can probably do no better than to state the method I have adopted in teaching surgical technic to the nurses of the North Pacific Sanatorium.

OUR METHOD.

We have our work printed in a little pamphlet entitled "Methodical Technic," which we use as a text, in which is described every detail. Every move in performing each act has been thoroughly studied before it has been adopted. Having been adopted it is followed to the letter, and we admit no other way than "Our way" for cleansing the hands: there is no other way than "Our way" for cleansing a field for operation: there is no other way than "Our way" for performing any of the details pertaining to surgical technic, unless it be by a special order of a physician in attendance. Every act must be first learned by a direct concentration of the mind on the details under supervision of the head nurses.

As an illustration of what I mean by detail, I will give a method of cleansing the hands.

METHODICAL CLEANSING OF THE HANDS.

1. With sterilized liquid green soap and sterile brush scrub the hands from the wrists down in the following order: Begin with the thumb on the left hand and scrub the thumb thoroughly in the following order: Radial side, dorsal surface, palmar surface, radial side again, end of finger and nail, root of nail, ulnar surface of thumb, interdigital space, radial side of index finger, dorsal surface, palmar surface, radial side, end of finger and nail, root of nail, ulnar surface interdigital space, radial side of middle finger, etc. Studiously scrub under and around every portion of the nail and surface and the space between the thumb and the index finger. Scrub the index finger likewise, carefully concentrating the mind on every move of the brush and paying special attention to the interdigital space. Continue across the hand, taking in all the fingers in a similar manner. Then take the thumb on the right hand and proceed across the right hand in like manner. Now begin again and scrub the left hand as a whole, beginning on the thumb side, passing over the back around the little finger across the palm and back to the thumb. Include the wrist in this scrubbing. Then a general repetition over the entire hand in the same manner, including the nails. Then the right hand in a similar manner.

2. Put down the brush and with a sterile nail file carefully clean under and around each nail, beginning with the left thumb, and take every nail in the order given for the scrubbing.

3. Soap the arms and hands from the elbow down with sterile green soap. Take a fresh sterile brush and begin with the left arm and scrub down to the wrist. Scrub the right arm in like manner. Then begin with the thumb and scrub the hands in the manner described in the first step.

In the formation of these habits the nurses must not be allowed to begin at any other point or to proceed in any other order than in the one laid down. There is no especial virtue in beginning at this particular point, but every time the hands are scrubbed in this manner the groove is deepened and the habit thus fixed which is to become indelible.

This process of washing the hands must be done at least once a day when the nurse is off duty, in order that she may devote her mind exclusively to directing the excursion of the brush over her hands. This is much more difficult for the graduated nurses or the operator than for the pupil nurse or student.

GENERAL RULES.

The following general rules are given:

1. Avoid contact with septic material the same as if you had no water, no chemical antiseptics and no artificial protection for the hands.
2. In preparing the hands or a field for operation do your work as thoroughly as if you had handled the most virulent septic material and had no antiseptic solution or artificial protection for the hands.
3. Use chemical germicides as faithfully as if you had handled septic matter, had not had the opportunity of using soap or water and had no rubber gloves.
4. When rubber gloves are used no less precaution should be exercised than if they were not to be used.
5. After these steps have been followed out avoid contact of the supposedly sterilized articles the same as if no cleansing had been done by either of the preceding methods.

These rules are given with the understanding that there are conditions under which they can not be carried out. These exceptions are given in a general way. If these rules are constantly borne in mind you will instinctively refrain from unnecessary handling of septic material.

Having come in contact with septic material you will instinctively refrain from touching anything with your hands until you have given them a thorough cleansing. Having mechanically cleansed your hands you will instinctively feel that they are still septic until you have used an antiseptic agent. Having cleansed everything as thoroughly as possible, you will still instinctively avoid unnecessary contact.

SUMMARY.

In summing up, we may, for all practical purposes, state that habit is a channel in the nervous system formed by the performance of a voluntary act, which channel becomes deeper each time it is used, but the wall of which is weakened when a varying or conflicting method is substituted. This difference may be likened to the difference between the channel of a river which has run for thousands of years in the same channel forming a deep canyon, and a river which runs through a sandy valley and which changes its bed to suit the various circumstances and climatic changes. We may say that habit is a mossback; is self-satisfied and never changes. Habit is a part of nature herself; is always true, therefore nothing can be safely delegated to habit which is subject to change. A surgical operation can not be delegated to habit, because we rarely find two conditions exactly alike. It always requires reason. In short, everything which can be made perfect should be delegated to habit. Nothing should be delegated to habit which is untrue or varying.

In instilling a habit first decide definitely what you want to teach. Second, do not overlook or neglect a single point or take anything for granted. Third, see that every point is carried out to the letter under the direction of a close observer. Fourth, accept no other way or excuse until the habit you wish to form is a part of the nature.

THE TEACHING OF THERAPEUTICS AND PHARMACOLOGY FROM THE EXPERIMENTAL STANDPOINT.

TORALD SOLLMANN, M.D.
Assistant Professor of Pharmacology and Materia Medica at the Medical Department of Western Reserve University.
CLEVELAND, OHIO.

INTRODUCTORY.

The most conspicuous tendency in the evolution of scientific instruction has been toward the introduction of laboratory methods: toward the substitution for authoritative statement, of direct observation, independent reasoning and a spirit of criticism. This method is particularly useful in medicine: for a student of the medical sciences is never merely a student, but by the very requirements of his calling he must be trained as an independent observer and thinker. The problems which his profession places before him can rarely be settled by reference to authorities, but must be approached by methods essentially similar to those employed by the experimental investigator. The training of a medical student should therefore be along experimental lines. Nevertheless, it is scarcely too much to say that teaching on an experimental basis is still in its infancy in medical schools. Reasons for this are not far to seek: Experimental medicine is of recent growth, and its introduction into teaching has been hampered by the existing organization of the medical schools: by the large number of students in comparison with the laboratory facilities: by the meager salaries of the instructors—in a word, by insufficient endowments. These adverse conditions still persist to a great extent, but the importance of scientific medicine has come to be so generally recognized that all difficulties had to be surmounted. Even the lowest types of medical colleges pretend to offer some laboratory courses.

It is a still more encouraging sign of the times, however, that the leading medical schools base their claims to leadership, not on the number of their students, but on the excellence of their laboratory instruction, including in this term the teaching of clinical subjects on a similar plan. Colleges less fortunate in their facilities are following this lead to the full extent of their resources. As a result of this tendency, medical teachers are being called on to organize new methods of instruction in an ever-increasing range of subjects. In this reorganization the instructor is at present thrown largely on his own resources, and his previous experience is of but limited applicability. He must practically start anew and learn by his mistakes. The waste along every line, which is inseparable from this method, could be greatly diminished if the beginning instructor could have access to the experience of others who have organized similar courses. It would therefore seem desirable that the instructors of such branches in a number of representative schools should publish in sufficient detail the organization and methods which have proved most successful in their experience. These outlines would supply valuable hints to schools in which new courses are in process of organization. They would serve to bring to the attention of even experienced instructors valuable features in the methods of their colleagues. They would have a tendency to foster uniform standards of instruction and requirements. Nor would such papers be without interest to the profession at large, for it may safely be affirmed that every practitioner is, or should be, interested in the advance of medical instruction.

That the desirability of such descriptions of new methods of teaching is being generally recognized is shown by the appearance, within recent years, of several monographs.[1] This recognition has encouraged me to present an outline of the course of pharmacology in actual operation in the institution with which I am connected.

PHARMACOLOGY A LABORATORY SUBJECT.

Therapeutics, or pharmacology, is peculiarly a laboratory subject. No branch of medical knowledge is more susceptible of experimental demonstration; none demands so imperatively an appeal to experimental methods and reasoning for its proper understanding. This view of therapeutics led me to the organization of a course which gives great prominence to experimental facts and principles. In substituting this experimental course for the older didactic method, the transition need not be abrupt. Demonstrations may at first take the place of the laboratory work, or the latter may be made elective. Indeed, the real essential is that the instructor cause the student to look on the subject as one capable of being treated by actual observation, experiment and independent thought. Laboratory work is, of course, a most potent means to this end. The instructor in a large subject like pharmacology must have a clear and definite idea of what he wishes to accomplish and of what he considers essential for the student to acquire. These aims he must take pains to keep constantly before the class. The course outlined by me is intended to furnish the student with an accurate knowledge and understanding of those facts about drugs which presumably will be useful to him in practice; to teach the effects as much as possible by direct observation: to foster a critical, inquiring, scientific spirit, independent thought and observation, and finally to give an introduction into the elements of research. To accomplish these objects the teacher does not teach in the ordinary sense—that is, didactically—but contents himself with encouraging, outlining, guiding, correcting, explaining, etc., the independent inquiries of the student, and in ascertaining that the work is done in a proper manner, and that the results come up to the set requirements.

GENERAL PLAN OF INSTRUCTION—REQUIRED WORK.

Lectures.—These are intended to give the student a general idea of the theme to be studied; to explain how to study this theme: to bring out the relative importance of particular facts or theories; to elucidate obscure or difficult points; to introduce the latest discoveries, and, finally, to give the teacher an opportunity to infuse into his subject and teaching the personal enthusiasm, interest, life and color, which can, after all, be given in no way as well as by oral lectures.

The lecture will naturally divide itself into three parts: 1, Outline of the subject; 2, elucidation of difficult points, and 3, new discoveries. To cover these subjects the lectures need not be exhaustive, since the student is expected to do his studying from his text-books. One lecture to three or four recitations suffices as a rule. The lectures should, if possible, be preceded by whatever elaborate demonstration is necessary. Simple experiments, diagrams, etc., are introduced directly into the lectures. The latter should be sufficiently short to hold the full interest of the students and teacher. Forty-five minutes are usually ample. During the fifteen minutes following the lecture the lecturer will answer informally individual questions by the students. The latter may also utilize this time to examine the materia medica specimens. The lectures are particularly a function of the head of the department. Attendance should not be obligatory.

---

[1] "On the Teaching of Pharmacology, etc." John J. Abel, Philadelphia Medical Journal, Sept. 1, 1890. "Some Forms of Apparatus, etc." E. T. Reichert, Univ. of Pennsylvania Medical Bulletin, June, 1901. "Physiology at Harvard," William T. Porter, Boston.

Recitations.—These are intended to accomplish the following: For the student they furnish a definite plan of study; help in fixing facts in the memory; bring out important points; teach him to keep his knowledge accessible; correct erroneous impressions; help to explain obscure points in the text and give opportunity to ask questions and to present his own views. To the teacher they give opportunity to develop the details of the subject systematically; to correct omissions in lectures; to bring out the way the subject should be studied; to judge the progress of the class and the individuals; and for deductive explanations.

To accomplish these objects the teacher, with the book before him, asks questions, in a systematic order, so as to cover the subject with fair completeness. The questions should be of such a nature as to bring out the knowledge of the student and to ascertain how thoroughly he understands and has mastered the facts. They should have a scope sufficiently wide to permit the student to develop the subject himself, the teacher interposing minor questions to give the recitation more of the nature of a discussion than of a recitation by rote. If a student blunder, another should, if possible, be made to give the right answer. The questions should never be leading; misleading questions are permissible. The teacher should return to the student until he has convinced himself of the knowledge of the latter, and should then give him a grade—preferably on the basis of ten.

For these recitations a certain number of pages of the text-book—from 8 to 15—should be assigned, the aim being to give a rounded-off subject. This should have been previously covered by lectures and demonstrations; but for certain subjects, or when time presses, recitations alone may suffice. It is recommended that the class have a uniform text-book, which should be in harmony with the general spirit of the course. I have elaborated a volume for this special purpose.[2] Collateral reading is also encouraged. The recitation may occupy the full hour, and may be given either by the head of the department or by assistants, according to the importance and intricacy of the subject. Attendance should be compulsory on three-fourths of the recitations, unless special excuses are accepted.

Demonstrations.—As many as possible of the important facts which are not covered in the laboratory work, should be verified by demonstrations. Simple experiments which consume only little time may well be worked into the lecture; longer experiments are given in a separate hour. The demonstrations should be so made as to be also lessons in technic and in observation. They should be accompanied by suitable remarks, which may be more empiric than in the lectures or recitations. Questions by the students should be encouraged. The demonstrations should be so arranged that they may be witnessed in detail by all members of the class. The latter must, if necessary, be divided into sections. A demonstration should not, as a rule, last over one hour, and, if possible, not more than forty-five minutes. The demonstrations may be given by the head of the department or assistants; or by advanced students under the direct supervision of the former. Attendance on three-fourths of the demonstrations should be compulsory, unless special excuses are accepted.

Laboratory Work.—The student, before beginning his pharmacologic work, should have mastered the technic of physiologic experimentation. The main object being to obtain results on the action of drugs, the preparation of the material for the experiments should be done by the staff as much as possible, the student thus having left more time and energy for the main object. If the students have not had sufficient preliminary training the experiments as given must be shortened and the course correspondingly extended. As the action of drugs always shows sufficient variation to leave a large scope to individual observation, it is better that the student should know what phenomena to expect, so as to seize the main results. Experiments can be carried out most successfully, and observations made most fully and accurately, when 6 men work on a mammal or 3 on a frog. The different manipulations and classes of observations should be made to alternate between the different members of the section, under the direction of the instructor. The latter should supervise not more than 18 men; and not more than 50 men should work in any room at one time. Chemical experiments should be made individually by each man, and one instructor will suffice for twice the above number.

Every subject covered in the laboratory should be preceded by a special "laboratory talk." This should take up the results to be expected; the deductions to be drawn from them; the points on which the observations should especially be made to bear; the explanation and demonstration of technic, etc. These talks are given whenever occasion demands, and may cover several laboratory exercises. For subjects not yet covered in lectures, the talk should be by the teacher otherwise it may take more of the form of a quiz.

During the laboratory exercise itself the instructor should confine himself to seeing that the work is properly done, and to giving indispensable help. The students should be encouraged to rely on their own resources, and their attention should not be distracted by quizzing. When some result of unusual interest is obtained by one of the sections the instructor may call the other men to witness it and he may give a brief extempore talk.

Unnecessary conversation, laughing, whistling and loud talking should not be tolerated. Each student must clean his working place before leaving the laboratory. If the apparatus permit, the entire class or section should work on not more than two experiments at the same time. This concentrates the attention of both students and instructor. On the other hand, the instructor should not allow a new experiment to be performed until all previous ones have been finished in a satisfactory manner. For this reason one day in four in the chemical work and one day in three in animal work should be left free for the repetition of faulty experiments. Those students who are not required to repeat experiments may elect to do additional experiments on these days.

With large sections it will be found better to have one-half of the section doing frog work, the other half mammal work. This requires less apparatus and gives some elasticity to accommodate an often fluctuating supply of mammals. The two halves alternate on successive days.

Laboratory Records.—Each section must keep detailed records of the results of the experiments in blank books furnished by the laboratory. The blanks for vivisections have printed headings.[3] Each report must be signed by the student reporting. At the end of the laboratory course these books must be provided with an index, as for example: "Strychnin: Exp. 2, page 1; Exp. 4, page 8; Exp. 5. page 10," etc. The books and tracings are then handed in, graded and retained on file in the laboratory. Students may copy whatever they wish from these records and tracings may often be returned on application to the instructor.

---

[2] T. Sollmann: "A Text-Book of Pharmacology." W. B. Saunders & Co.

At intervals a laboratory discussion is given. This is made to cover the two or three preceding experiments, questions being asked by the instructor to bring out the results, which are then discussed by the class. This discussion should be conducted by the head of the department. The remainder of the laboratory work may be given by assistants under the supervision of the head of the department. Three to four hours should be allowed for each vivisection experiment, two hours for frog experiments and one to three hours for the chemical experiments. Attendance on four-fifths of the actual laboratory work should be compulsory and insured by roll-call.

Materia Medica.—This subject is taught in direct connection with pharmacology, the idea being to familiarize the student with the preparations in which the drugs may be prescribed: their dose, miscibility, general appearance and physical characters. On account of the very great number of practically obsolete drugs and preparations, this requires careful selection.

A rather extensive collection of materia medica comprising organic and inorganic drugs, their preparations, active principles, etc., is kept easily accessible in glass cases. They are arranged by the groups used in the teaching. Each bottle, in addition to the name of the contents, bears one of the following labels: "Strong Poison, Do Not Taste," printed on red paper; "Poison, Taste Cautiously," printed on blue paper, or "Practically Harmless," printed on green paper. Also one of the following white labels with the imprint, "Identification," in red letters, "Important" in blue letters, or "Unimportant" in black letters. The "Identification" bottles contain the specimens which the student must be prepared to identify. They are always placed toward the right hand of the shelves. The bottles are numbered consecutively and by shelves and cases, there being a card index to the collection. A single key fits all the cases, and will be lent to any student on application. There is also an herbarium and a collection of water-color illustrations of important plants.

These collections are utilized as follows: They are brought out and placed on the lecture table during the preliminary lecture on the group, the lecturer calling attention to the characters of the more important specimens. They are examined by the students during the quarter hour following the lecture. They are then exposed on a side table in the lecture room for one week. The "Identification" specimens are then placed on a conspicuous shelf in the lecture room, easily accessible to the students, and left there until the end of the course. During the recitation a few specimens considered in the preceding lecture are passed around for identification. The "important" and "unimportant" specimens are returned to the museum at the expiration of the week. The students are directed to study the specimens in such a way that they will be able to name the "Identification" drugs from the unlabeled specimens; with the "Important" they should be able to say whether or not an unlabeled specimen could be, for instance, arsenious acid; while the "Unimportant" need merely be glanced over.

Prescription Writing.—The systematic study of this subject comes in the early part of the course in the sophomore year. After a quiz on the book, five hours of exercises and five lessons for home-work are given at convenient times, to illustrate the construction of prescriptions and the manner of prescribing different classes of preparations—such as liquids, pills, ointments, etc. For this purpose four men are called to the blackboard; the instructor gives out two prescriptions, in the briefest shape possible, one to each alternate student. These the students write out; they are then criticised by the class and the instructor; and four other students are called up, etc. Prescriptions are similarly assigned for home-work, and are graded and returned by the instructor.

In the junior year five hours and five home lessons are distributed through the year, the exercises being conducted in a similar manner. In these drills the application of a given group of drugs, or the treatment of a given condition of disease, is given out, the students being required to fill in the necessary details according to their judgment.

Incompatibilities.—The most important incompatibilities are brought out in the laboratory work or shown in a demonstration. They are then recited on in three hours. Incompatible prescriptions are placed on the blackboard about ten times at intervals during the course; these are criticised by the students, the rule according to which they occur being every time quoted in full. A similar course is followed when incompatibilities occur in prescription writing.

OPTIONAL WORK.

The following courses of conferences, theses and research are designed to foster original thought and investigation by the students. An hour a week for eighteen weeks is given to the discussions; conferences alternating with theses. The program is announced in advance. Experimental research is specially arranged for.

Participation in these courses is purely voluntary, but they deserve the active support of the students on account of their importance and in return for the sacrifice of time and labor on the part of the instructor.

Conferences.—These comprise three heterogeneous features: The question box, reading of abstracts and compilation of reports.

The Question Box.—This feature is designed to open for discussion questions which are of especial interest to the class, outside of the order treated in the lectures. A box is kept in the lecture room into which students may place questions, signed with the name of the enquirer. These questions are answered at the discretion of the instructor in the conferences within two weeks. Any question relating to pharmacology will be considered pertinent. The answer may, however, take the form of a reference to the place where further details may be sought.

Abstracts and Criticism of Original Papers.—Even the most advanced text-books give an inadequate idea of the spirit of an advancing science. This can only be obtained by research and the perusal of original papers. The latter has the further advantage of familiarizing the student with the methods of keeping up with the progress of medical science.

---

[3] The table is headed: Date —; Section —; Reporter —; Experiment Number —; Animal —; Age —; Sex —; Anesthetic —; Then follow columns for recording the following: Time; Drug; Dose pr. Kg.; Strength of Solution; Manner of Injection; Heart: Rate, Regularity, Tracing and Strength; Respiration: Rate, Strength, Tracing; Blood Pressure: Mean Height, Extremes, Respiration Variations, Tracing; Urine, Flow; Venous Pressure; Intestine: Color, Peristalsis.

To secure this object the students who are willing to participate in this feature of the course are requested to hand in cards bearing their names and a list of the languages which they can read. The instructor selects a number of names and gives to each an original paper,[4] which is to be abstracted and returned within two weeks. The abstracts should be from about 100 to 500 words, and should consist of a table of the contents of the paper, an outline of the method adopted, and the conclusions, with criticisms and suggestions for further research. The abstract should be, as far as possible, in the student's own words. The abstracts are handed in to the instructor and criticised by him. When the student wishes to be assigned another paper he again places his name in the box. From these abstracts the instructor will select a certain number to be read before the class in the conference hour. These will then be subjected to criticism by the class and instructor, as regards the paper, the subject and the abstract itself.

Compilation of Reports.—The drafting of conclusions from the facts furnished by a considerable number of experiments possesses great importance—not only in experimental research. but also in clinical observation. As a practice in this class of work the reports on experiments on file in the laboratory, as well as the tracings relating to them, will be given out to volunteers. The instructor will outline the manner in which the compilation is to be made. The student will then draw the conclusions justified by the experiment. and submit them to the instructor. At the discretion of the latter these will be read and criticised in the conference. The work must be handed in within two weeks. The general treatment is to abstract the important points from each report, and from these results to present a picture of the action of the drug under the condition of the experiment.

The compilation may bear either on a given experiment—say Exp. 2, Mammals; or more usefully on a single drug, or one of the phases of its action, such as the action of strychnin on the circulation and respiration; the action of drugs on the eye. etc. The effects should be noted, qualitatively and quantitatively, for different doses and time of action. The results should be presented both by "means" and averages. Important representative tracings should form part of the report. General conclusions should be drawn as far as the data permit. Special attention should be given to atypical and unusual results. If the student desire, he may make this compilation the basis of a thesis by enlarging on the general bearing of the results, comparing them with the statements of text-books and investigators, etc.

Reading and Discussion of Theses.—This feature is intended to give the students practice in writing, reading and discussion of papers. The students who wish to participate in this course are requested to hand in their names to the instructor. A week before the meeting three names are chosen by lot from these cards. The first drawn (A) will preside during the meeting—the first two or three meetings, however, being conducted by the head of the department. The other two (B and C) will lead the discussion. All three will be expected to familiarize themselves with the subject and to prepare beforehand a list of topics for discussion. The function of the instructor during these meetings will be merely that of advisor to the chairman and of final critic.

The value of the course will depend largely on the discussion following the paper. It is the duty of the chairman to see that this discussion is generally participated in. He also passes on the topics for discussion and places a list of them on the blackboard. Questions of fact are referred by him to the reader, or to the men leading the discussion. The chairman is at liberty to devise his own program. The following is submitted for his guidance:

1. Reading of paper.
2. Suggestion of topics by reader, B, C, class, A, instructor. Of these the chairman will make a selection and write these on the blackboard in the order in which he wishes them discussed.
3. Question of facts and observation, B, C, class, A, reader, instructor.
4. Statement of views and theories, with reasons for same (order as in 3).
5. Discussion of views and theories (order as in 3).
6. Summary by the instructor.

In case the reading and discussion of a thesis occupies more than one meeting the chairman will be retained until it is disposed of.

The Theses.—The papers should aim to give either an original presentation of a subject, or a critical compilation of the literature, or to bring out and discuss obscure and disputed questions concerning the theme. The themes of theses may be any subjects connected with pharmacology, as any pharmacologic group, such as antipyretics, atropin, local anesthetics, etc.; or the pharmacologic treatment of any disease or condition, as, for instance, pneumonia, pain, etc.; or the treatment of cases under the writer's observation; or summarized reports of experiments or research; or historical or bibliographical.

The titles of the theses read in 1902 will give some idea of the scope of this course:

Hot, Cold and Vapor Baths; Their Clinical Effect.
Medullary Stimulants.
The Food Value of Alcohol.
Cocain, Historical Survey of Research on.
Cocain, Collection of the Laboratory Experiments on Frogs.
Caffein, Pharmacologic Summary.
Picrotoxin, Effects on the Frog.
Fish-poisons.

The writing of theses is entirely optional and the choice of the subject is also left to the student. They will be read in the order in which they are received, the program always being announced a week in advance. It is well for the instructor to suggest at first some topics from which selections may be made. In writing theses the aim should be conciseness combined with clearness. All interesting matter pertaining to the subject should be presented, but the topic should be sufficiently restricted so that the reading of the paper should not extend over 15 minutes—5 to 10 pages quarto. Only one side of the paper should be written on, and a wide margin should be left for notes. The reader will also make a brief report of the discussion and append this to his paper. The theses are kept in the files of the laboratory. The reading of the paper should be done slowly, emphasis being laid on important points. The mere reading of figures, etc.. should be avoided. When figures, curves, etc., occur in the paper these should be placed on the blackboard before the meeting. A talk from notes may take the place of a regular thesis if preferred by the student.

---

[4] The following journals will be found most useful in this connection: Am. Jour. of Physiology (Boston); Journ. of Experimental Medicine (Baltimore); Journ. of Medical Research (Boston); Journal of Physiology (Cambridge, England); Archiv f. Experim. Path. und Pharmakol. (Strassburg); Archives International de Pharmacodynamie (Paris).

Experimental Research.—Research by the students is encouraged in every way possible. All the resources of the laboratory and the advise and aid of the research staff are placed at the disposal of those willing and able to do research, without cost, except for animals or unusual apparatus or material.

Research work is divided into the following classes: 1. Assistance to the research staff. 2. Verification of a published research. 3. Joint research with a member of the research staff. 4. Independent research of subjects selected by the student or suggested by the instructor, under the supervision of the latter.

Students or others who volunteer will be assigned to one or the other of these classes at the discretion of the instructor according to their ability, previous experience or other conditions.

REVIEWS, TESTS, EXAMINATIONS AND GRADING.

Reviews.—The reviews are intended to cause the student to review the subjects covered, in order to impress them collectively and in their relation. They also aid, of course, in remembering and in preparing for tests. They are given as quizzes, the main or representative facts being brought out by rapid questioning. No grades are given. The reviews follow closely on the conclusion of the corresponding chapters and are announced three weeks in advance. They cover:

1. Sollmann's Pharmacology,	Chapters	1 to	6	inclusive.
2. "	"	"	28 to 32	"
3. "	"	"	7 to 16	"
4. "	"	"	17 to 23	"
5. "	"	"	24 to 27	"

Just preceding the final examination these review quizzes are repeated.

Written Tests.—These are given to control the progress of the students and to train them in the writing of papers. The papers are graded by the instructor or assistants and returned to the students; the grades in recitation, etc.. to date are also noted on the papers. The instructors will positively not discuss these grades with the students. All possible care is used to make the grading just and exact, and it would consume altogether too much of the instructor's time to justify and argue his decision with each student.

The questions in these tests are such as would be given in regular examinations. Each question counts an equal number of points. Each test includes about three questions and five specimens, and one hour is allowed for the answering. The tests cover the same subjects as the reviews and follow the reviews in about two weeks.

Final Examinations.—The examinations are written, oral and practical. All are intended and arranged so as to give a real conception of the knowledge of the student, rather than make him conform to any arbitrary standard; this is the cause of the division into the three above captions. The final examination covers the entire subject. The written and oral examinations are given in the first and last week of the school year.

The Written Examination.—A list of questions, of which the following is an example, is submitted to the students. The questions should be as general as possible.

1. Write a prescription for a diuretic mixture containing (a) a drug stimulating the renal cells; (b) one acting as a salt or alkali; (c) as an organic irritant; (d) as a cardiac tonic; (e) flavor, vehicle, etc. Write the names without abbreviations, and give the quantities in both metric and apothecaries' systems.

2. Describe the different ways in which antipyretics may act, and the ways of differentiating between these. Give examples.

3. Discuss the theoretical basis of the action of potassium iodid.

4. Name one or more drugs which may be employed to secure: (a) stimulation of the arterial muscle; (b) paralysis of arterial muscle; (c) paralysis of vagus ganglia; (d) stimulation of vagus center; (e) stimulation of cerebral cortex.

5. Name six of the most important emetics, stating dose for adults (metric system).

6. Discuss fully the pharmacology, symptoms, antidote, and therapeutics of one of the following drugs: Aconite, acids, mercury.

7. Identify the 20 specimens submitted, giving correct Latin name, and the dose.

8. Explain the incompatibilities in the three prescriptions submitted to you (7 and 8 are graded separately).

The questions are to be answered in writing as exhaustively as the time (three hours) will permit. Nothing is taken for granted which is not unequivocally stated in the paper. Every point covered by the questions should be fully treated in the answer; but nothing should be stated in the paper which is not directly asked for in the questions. Some attention should also be given to style. It is suggested that in writing out the answers the student should dismiss at first whatever points he does not feel certain of, and should fill these in only after he has answered those questions which he knows more fully.

Oral Examination.—Each student is examined for ten to thirty minutes, or until the examiner is convinced that he has the range of the student's knowledge. It is the object of the examiner to conduct this quiz in such a way as not to confuse the student; in case a wrong answer is given the instructor will attempt to find out whether this is the result of confusion or ignorance.

Supplementary Examination.—If the attendance on recitations has not been satisfactory the student will be required to take a supplementary examination of a somewhat more severe grade than the regular examination. If the grades of the class work, oral and written examination are conspicuously at variance, the student will be cited to furnish an explanation of the discrepancy, and may be subjected to a supplementary examination. This may be written or oral, at the discretion of the instructor.

Laboratory Examinations.—These immediately follow the conclusion of the chemical and animal laboratory work. Only students whose laboratory attendance has been satisfactory will be admitted. The object of these examinations is to judge the ability of the student to do laboratory work. To arrive at this he is obliged to work out independently certain problems which are to some extent elective; the use of books is permitted, and the instructor will give whatever aid he considers indispensable. At the conclusion of the laboratory work a list of five to twenty problems is posted. These involve principles similar to, but not identical with, those of the regular experiments. Within a week each student must make a choice of three of these problems, one of which will then be assigned to him for solution. Small sections will begin their work each week, under the personal supervision of the staff. The problems will be so arranged as to require from five to twenty hours of work, and the results must be presented in the form of a thesis. Students may elect to take regular research work in place of the laboratory examination. The grading will take account of the difficulty of the problem, the time required, the method pursued, technic, the results and the thesis.

The following list of questions from the examination in chemical laboratory work of the past year will give an idea of the scope of these examinations:

a. Investigation of the incompatibilities of certain substances, mainly alkaloids or new synthetic compounds.
b. Isolation of a given constituent from a drug.
c. Effect of pepsin on ferments.
d. Effects of antiseptics on ferments.
e. Effects of antiseptics on bacteria.
f. Laking agents.
g. Chemical assay of a vegetable drug.
h. Testing drugs for purity.
i. Investigation into the chemical reactions of synthetic substances.
k. Making a line of pharmaceutical preparations.
l. Making a toxicologic analysis.
m. Investigating microchemical reactions.
n. Methods of estimating the amount of digestion.
o. Isolation of poisons from urine.
p. Determination of lethal doses on frogs.

Grading.—In determining the final grade of the student a system should be used which is sufficiently rigid to secure a uniformity of standard, and yet sufficiently elastic to allow for the personal judgment of the instructor as to the student's qualifications. It should take account both of the quality of the class work throughout the year and of the final knowledge as shown by the examination. I have elaborated the following scheme, which seems to me to secure these objects as well as can be and which I have applied with satisfaction:

a. All the grades of the student are carefully looked over, and a grade assigned to him without any mathematical computation, from judgment and from personal knowledge alone.

b. 1. The grades of the recitations and tests are averaged, and calculated on a basis of twenty-five. 2. The grades of the daily laboratory work, laboratory examinations, prescription writing, and examination questions of identification of specimens and incompatibilities are averaged, and calculated on a basis of twenty-five. 3. The grades of the written and oral examinations are averaged and calculated on a basis of fifty. The sum of these gives the calculated grade.

c. (*a*) and (*b*) are compared: If they approach within five points, as is almost invariably the case, the average is taken. If a larger discrepancy exists, the cause of this is inquired into and the grade adjusted accordingly. The student then may, if necessary, be required to take the supplementary examination.

The following two examples, taken from the record of the last class, will illustrate:

	Student X.	Average on basis of 100.	Student Y.	Average on basis of 100.
Grades on a recitation basis of 10.	6, 8, 10, 9½, 9, 10, 10, 10.	91	8, 8, 4, 8, 8, 7, 5	69
Tests on basis of 100.	66, 94	80	62	62
Daily laboratory work	. . . .	95	. . . .	87
Laboratory exam.	. . . .	95	. . . .	90
Prescription writing on basis of 10.	9, 10, 8, 10, 10, 10, 9, 9½	95	9, 9, 8, 7, 8, 9, 6	80
Identification exam.	. . . .	75	. . . .	90
Incompatibilities examination. . . .	. . . .	90	. . . .	60
Written examination.	. . . . . .	99	. . . .	34
Oral examination. . .	. . . .	92	. . . .	65

Following the plans given above, there results:

	Student X.	Average on basis of 100.	Student Y.	Average on basis of 100.
Adjudged (by Plan *a*).	. . . . .	95	. . . .	63
Figured (by Plan *b*)	. . . . .	92	. . . . .	61½
Accepted as real final grade . .	. . . . .	94	. . . . .	62

ORGANIZATION OF THE PHARMACOLOGIC LABORATORY.

The object and general methods of the laboratory course have already been sufficiently outlined. The text-book gives a series of finished experiments, but these may be enlarged or modified at the direction of the instructor, the book furnishing sufficient hints for this purpose. In this connection it may be said that, if time and material permit, it might be preferable to cut down the length of experiments and give a larger number. The best way, however, to accomplish this is to let the students work on an experiment, and if this does not come to satisfactory conclusions, to let them begin next day where they left off. When dogs are difficult to obtain, experiments on rabbits may be used for all but blood-pressure work. Cats answer well for all experiments.

Arrangement of Sections.—The students are divided into sections; six for mammals, three for frogs. These sections the men are asked to organize for themselves; those who have not joined a section when laboratory work begins will be assigned to one by lot. Every student is considered responsible for the results of the entire experiment, although a definite part is assigned to him particularly. When his own part does not demand his entire attention he is expected to give aid to the other members of the section. The student in charge of the section is to attend to this and to give directions, decide on methods, etc. He should also bring with him a list of the reagents and apparatus required for the experiment, so that there may be no delay in getting these out. The members of each section are lettered A, B, C, D, E and F. To secure a proper rotation of the work this is divided and exchanged as follows:

FROG WORK.

Place 1.—In charge of entire experiment; in especial charge of experiments on eyes, and of electrical apparatus.

Place 2.—In charge of drum and tracings, and of experiments on heart and muscle, and of cleaning.

Place 3.—In charge of report, of operations, and of experiments on heart and muscle.

A and D, B and E, C and F always have the same place; in the first experiment A and D have Place 1, etc.; in the second experiment A and D have Place 2, C and F Place 1, etc.

MAMMAL WORK.

Place 1. In charge of the entire experiment; preparation of report; observation of general condition of animal.

Place 2.—Taking of notes; giving of anesthetic; general aid in operations; respiration tracings.

Place 3.—Operations and attachment of apparatus in neck; making of injections; observations on heart; pulse and respiration.

Place 4.—Operations and attachment of apparatus to thorax; blood-pressure tracings.

Place 5.—Operations and attachment of apparatus to abdomen; observations on abdomen or vein manometer; cardiac tracings.

Place 6.—Calculation of doses and preparation of solutions; artificial respiration; subsidiary experiments; cleaning.

A will have Place 1 with the first experiment, Place 2 with the second, etc.

Equipment.—The laboratory should be supplied with chemical work tables and sinks; a fume chamber; large water bath for 40 and 100 degrees C.; dog and rabbit boards; analytical balance; scales weighting 0.01 gm. to 20 gm.; 1 gm. to 3000 gm. and 100 gm. to 50 kg.; large bottle with siphon for normal salt solution 0.75 and 0.9 per cent.; large bottle of anesthetic; jar for distilled water; jars for waste; bone shears; bellows (14x20 inches); operating instruments for instructor; tables, etc. The cost of this common apparatus, outside of tables and the analytical balance, need not exceed $50.

The tables are solidly constructed of pine and receive two coats of boiled oil. They are 36 inches high; the tops are of 1¼-inch board and project 2½ inches beyond the legs. Each section should have two tables—one 36x36 inches for apparatus, and one 20x60 inches for animals. The head-fasteners and screw-eyes for securing the animals may be attached directly to the latter table, thus doing away with separate dog-boards. The apparatus tables may also have the manometers permanently fixed to them.

Students' Equipment.—Chemical Work.—Two men are assigned to each locker, and each man is furnished with a key. The lockers contain the material enumerated below. If the laboratory does not possess a sufficient number of a given apparatus, this may be kept out and assigned on requisition. The same holds true of animal experiments. Additional apparatus may also be obtained on requisition. All charges are made against the locker. Before being assigned to a locker each student must make a deposit of $2.

CONTENTS OF CHEMICAL LOCKERS, FOR TWO MEN.

Article.	Cost per Piece.	Cost per Set.[5]
1 Bunsen burner and tube	$0.40	$0.40
2 rings	.35	.70
1 wash-bottle, 1 L.	.75	.75
2 evaporating dishes, 10 cm.	.30	.60
2 funnels, 6 cm.	.10	.20
2 beakers, 25 to 100 c.c.	.17	.34
2 flasks, 250 c.c.	.18	.36
2 tumblers	.05	.10
50 test-tubes	.03	1.50
2 test-tube racks	.30	.60
2 test-tube brushes	.05	.10
1 sponge	.05	.05
1 earthen jar	.10	.10
2 exercise books	.25	.50
1 test-tube clamp	.05	.05
1 mortar, 7.5 cm.	.40	.40
1 pill tile, 12x12 cm.	.40	.40
1 spatula, 10 cm. blade	.25	.25
1 pill box	—	—
1 powder box	—	—
1 graduate, 25 c.c., conical	.35	.35
1 tripod	.25	.25
1 iron waterbath and tripod, 13 cm.	1.60	1.60
1 thermometer, 0-100 degrees C	1.00	1.00
1 separator, 250 c.c.	1.50	1.50
1 spectroscope	6.00	6.00
2 watch-glasses, 1½ inch.	.05	.10
1 towel	.10	.10

The cost of a complete chemical equipment for two men therefore amounts to not more than $19, and by having the more expensive apparatus in common it may be reduced to $10.

Animal work.—Six men are assigned to each locker, the key of which is kept by the instructor and given out by him on application from a member of the set.

CONTENTS OF ANIMAL LOCKERS.[6]

The letters after the name of the article refer to the source whence they may be obtained.[7]

Article.	Cost per Piece.	Cost per Set.
2 drums (*a*)	$12.00	$24.00
2 induction coils (*a*)	5.00	10.00
2 electrodes (*a*)	—	—
2 contact keys (*a*)	1.00	2.00
3 dry batteries (*d*)	.25	.75
1 bichromate battery (*d*)	1.25	1.25
Insulated wires; 8 coarse and 4 fine	—	—
1 spool thread	$0.05	$0.05
1 spool silk	.05	.05
2 aneurism needles (*d*)	.35	.70
2 frog needles (*c*)	—	—
2 pithing needles	—	—
2 muscle-levers (*a*)	1.05	2.10
2 heart-holders	.75	1.50
1 cork of pins	—	—
6 cork boards	—	—
2 boards for frog circulation	—	—
2 beakers, 50 and 100 c.c. (*b*)	.15	.30
1 funnel, 6 cm. (*b*)	.10	.10
3 tumblers	.05	.15
1 earthern jar	.10	.10
Reeds and straws	—	—
1 gag	—	—
2 *sponges*	.05	.10
3 towels	.10	.30
2 porcelain capsules, 10 cm. (*b*)	.30	.60
1½ gal. tin bucket, with hook	.10	.10
2 10 gm. weights (*c*)	—	—
1 250 c.c. flask (*b*)	.18	.18
1 stomach catheter (*d*)	.25	.25
50 cm. glass syringe (*b*)	.20	.20
4 bull-dog forceps (*d*)	.35	1.40
1 aspirator syringe	1.00	1.00
Large and small aspirator needle (*d*)	.20	.40
1 thermometer 1-100 degrees C. (*b*)	1.00	1.00
1 clinical thermometer (*d*)	.60	.60
1 respiration bottle (*c*)	—	—
2 rods for lever respiration (*c*)	—	—
2 retort standard 1/15 in-1/20 in. (*b*)	.45-.65	1.10
3 clamp fasteners (*b*)	.25	.75
2 burette clamps (*b*)	.75	1.50
1 ring (*b*)	.35	.35
2 Bunsen burners with tubes (*b*)	.40	.80
1 tambour (*a*)	1.00	1.00
1 suture needle (*d*)	.10	.10
1 mercury manometer (*a*)	1.00	1.00
1 water manometer (*c*)	—	—
3 pipettes (*c*)	—	—
2 feathers	—	—
2 frog-report books	—	—
1 mammal-report book	—	—
Set of ligatures, heavy cotton	—	—
Set of 6 blood canulæ (*c*)	.10	.60
Set of 3 tracheal canulæ (*c*)	.10	.60
Set of 3 urethral canulæ (*c*)	.10	.30
1 bladder canula	.15	.15
1 frog's aortic canula (*a*)	.10	.10
1 T-piece, large (*b*)	.25	—
1 Y-*piece small* (*b*)	.25	—
1 Y-piece large (*b*)	.25	.75
Rubber tubing, 3 oz. (*b*)	.20	.60
10 test-tubes (*b*)	.03	.30
1 test-tube rack (*b*)	.30	.30
2 Mohr's clamps (*b*)	.15	.30
2 valves for William's apparatus (*b*)	.35	.70
1 *screw clamp* (*b*)	.30	.30
2 wire bull-dogs (*b*)	.15	.30
1 Woulf's bottle, 2 necks, 250 c.c. (*b*)	.45	.45
1 bell jar, narrow, open neck 1 L (*b*)	.45	.45
1 fine forceps (*d*)	.50	.50
1 tripod and gauze (*b*)	.25	.25
1 25 c.c. measure (*b*)	.35	.35
1 test-tube brush (*b*)	.05	.05
1 curved iron clamp (*a*)	.15	.15
Sealing wax	—	—
Parchment	—	—
1 heavy weight for mammalian heart	—	—
1 small drawer for transporting	—	—
1 box labels	—	—
1 set dog ropes (*c*)	—	—
1 set rabbit ropes (*c*)	—	—
2 binding screws	.05	.10
1 injection burette	1.40	1.40
1 mortar and pestle, 7.5 cm.	.40	.40
1 glass rod	—	—

It is requested that these pieces be kept in their proper drawers. A tool-chest will answer very nicely. The cost of the apparatus for a set of six students will not exceed $65.

---

[5] The prices are those quoted by a large firm dealing in such supplies and are those charged to students. When chemical apparatus is imported duty free, the cost of the college course will be considerably less.

[6] Very excellent and low-priced physiologic apparatus is manufactured under the supervision of the Harvard Medical School, and may be obtained through Prof. William T. Porter, Boston.

[7] *a*. Harvard, see note 6, above. *b*. Chemical Supply Houses. *c*. Home-made. *d*. Surgical Instrument Stores.

Animals.—The animals are only given out on requisition. Each section of six men is entitled to 50 frogs and 12 mammals. Animals beyond this number will be charged for at the rate of 10 cents for each frog, 60 cents for each rabbit or dog and 40 cents for guinea-pigs.

Reagents.—Two sets of the more commonly used reagents and one set of those more rarely used are placed on each table intended to accommodate six men. These are arranged alphabetically and numbered consecutively, the student being requested to replace each bottle in the proper order as soon as it has been used. The only exception to this are the reagents for experiments 5 and 9, a set of which is kept on a separate shelf. It is the duty of the assistant to see that the bottles for the current experiments are properly filled.

For the animal experiments a special shelf is kept on which bottles of all reagents for each set are arranged alphabetically and properly numbered. The reagents for the current experiments are removed to a separate and easily accessible shelf. The Harvard plan of having but one stock bottle for each reagent, a dozen empty bottles for each set and a set of exchangeable tag labels—the bottles for each set being relabeled and refilled for each experiment—could be substituted. The cost of reagents for the chemical and animal work need not exceed $100 per year for a class of fifty students.

ARRANGEMENT OF TIME AND SUBJECT MATTER.

A course of the kind which I have outlined above. and including pharmacology, in relation with therapeutics and toxicology, materia medica, pharmacy, prescription writing and laboratory work requires:

Hours for regular lectures, demonstrations, tests, reviews and other class-room work	110
Hours for elective conferences and theses	18
Hours for laboratory	120
Total hours	248

In our course part of this work is placed in the last weeks of the sophomore year, part continues through the junior year, the juniors receiving 77 hours of class work, 70 hours of laboratory work and 18 hours of optional conferences. The sophomores receive 34 hours of class work and 48 hours of laboratory work. The hours are distributed as follows:

SOPHOMORES.—After March 1—Class-work: Monday and Tuesday 10 to 11, Thursday and Friday 9 to 10. Laboratory work: Monday and Tuesday 11 to 12, Thursday 10 to 11, Friday 10 to 12.

JUNIORS.—Class-work, entire year, Monday and Thursday 8 to 9, after January 1: Monday 2 to 3. Laboratory work: To January 1, Monday, 12.30 to 4; Wednesday 3.15 to 6.15. Optional conferences and theses (alternating) after January 1, Wednesday 3 to 4.

DISTRIBUTION OF LECTURES, RECITATIONS, DEMONSTRATIONS.

The following will give an idea of the hours allotted to each subject:

	Lectures.	Recitations.	Demonstrations.
Pharmacognosy, pharmacy, pharmaceutical assaying, toxicological analysis, flavors.	1	8	4
Prescription writing	—	10	—
Introduction to pharmacology	2	1	—
Strychnin, caffein and picrotoxin groups.	1	4	2
Morphin, cannabis, hydrastis, cocain groups	1	4	1
Atropin, nicotin, pilocarpin, physostigmin, etc.	1	4	1
Internal secretions, emetics, aconite, veratrin, quinin	1	4	1
Coal-tar derivatives, toxins	4	3	—
Hydrocarbon narcotics,	1	4	1
Gases, camphor, cyanids, nitrites	1	2	1
Digitalis, ergot, sapotoxin	1	4	1
Salt action	2	3	—
Ion action of neutral salts, acids and alkalies	1	4	—
Systemic action of metals	1	3	—
General irritants	1	4	—
Stomachics, cathartics, anthelmintics	—	3	—
Demulcents, emollients, nutrients	1	2	—

In concluding, I wish to reiterate that my purpose in writing this paper has been, to place before the profession *one* scheme of teaching these subjects. I feel convinced that similar expositions from other teachers, either in journals or by correspondence, would be of great mutual advantage.

THE PLACE AND IMPORTANCE IN THE COLLEGE CURRICULUM OF MATERIA MEDICA.*

WARREN B HILL, M.D.
MILWAUKEE, WIS.

Notwithstanding that about 95 per cent. of medical practitioners devote nearly their entire time to the practice of internal medicine by the application of remedies found in the materia medica, the greatest interest in the profession is centered upon therapeutic agents other than medicine. Looking over the programs of several state medical societies it is observed that nearly all the papers read are along the lines of surgery or some kindred topic. In the smaller medical societies only an occasional hour is given to the subject of materia medica or therapeutics. The text-book of to-day on internal medicine devotes little space to the treatment of disease and almost none to subjects pertaining to our materia medica, while whole volumes in surgery are devoted to surgical therapeutics. Among the younger members of our profession the brightest minds are allured by the brilliant successes of surgical therapeutics. Our pathologists study their science from an anatomic standpoint almost to the exclusion of functional pathology, and, indeed, some of them say there is no pathology when no structural changes are noticed, however evident the functional disturbance may be.

In the curricula of our medical colleges a great percentage of the time is given up to surgery, surgical anatomy, surgical pathology and kindred branches, while materia medica and its sister branches of pharmacy and therapeutics are given a minor place.

A surgical clinic attracts a large audience, while only a few remain to witness a clinic of internal medicine, and then the clinician seldom discourses upon that which he hopes will effect a cure for his patient. I do not speak of this state of affairs as a protest against the indifference for the consideration of our subject, but hope to call attention to the facts as they exist and see if we can locate the cause for this condition in the education of the doctor.

The reason that surgery is so attractive and so remunerative to its followers is that the whole system is built on therapeutics. The anatomy and the pathology that he studies is made subservient to his ultimate purpose, the cure of his patient; and surgeons never tire of listening to discussions as to the best method of operative procedure, even to the finest detail. Even the tying of a peculiar knot in a ligature has entertained an audience in the American Medical Association, and the essayist has received the applause and congratulations of his colleagues.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

Not so in internal medicine. Some of the leading lights in this branch of medicine say, with a measure of pride: "We know nothing of therapeutics and less of materia medica."

In some of the largest clinics in this country and in Europe the clinician, after an exhaustive study of the scientific aspect of his case, not only says little or nothing about those agents which might be brought to bear to cure the patient, but does nothing, and apparently waits, rather impatiently, for the postmortem to verify his opinions as to the pathology of the case.

He who aims to practice medicine for the good he may do or who hopes to build a practice by the results he achieves, finds little allurement in ante-mortem theorizing and postmortem verification. Our patients come to us to be cured, and when internal medicine shall make the means of cure its central figure and the purpose of the study of diagnosis and pathology, normal and pathological physiology, lead the way to therapeutics, then will the therapeutics of the materia medica interest the practitioner as does surgical therapeutics.

One of the noticeable things of to-day is the skepticism of the profession regarding drugs. The cause of this is, no doubt, the natural reaction from credulity. The young physician, and sometimes the older one, believes what some fellow physician or some traveling salesman says of the efficacy of particular drugs in particular diseases; and when disappointment overtakes him, as it surely must, he is prone to condemn drugs in toto.

How few physicians know the exact physiologic action of the drugs they use every day in their practice! How few take the same interest in functional disturbances that they do in organic lesions! It is as important to understand the physiological action of the agents employed in the cure of disease as it is to recognize the pathologic conditions, both functional and structural, in the patient. It is as essential to know the limitations of the agent as it is to know its potency.

A few years ago the wise men proclaimed that our materia medica would be relegated to the archives of ancient history in a very short time. The signal success of diphtheria antitoxin forecast in their minds an era when the hypodermatic syringe and the box of assorted serums would be the complete armamentarium of the future doctor. Time has not verified their predictions, nor has it added many successes along the line of serum therapeutics; but the investigations of these enthusiasts have given us a rational explanation for the use of many drugs. The knowledge that we now possess of cellular activity and the cause of disease should be a stimulus to a more scientific study of the remedial agents found in materia medica. Recognizing the fact that all doctors rely upon these remedial agents most of the time, and most of the doctors rely upon them all of the time, we must conclude that materia medica should have a very prominent place in the curriculum. The teacher should be an enthusiast in order to inspire the student. He should have that confidence in his subject that is gained by thorough knowledge and happy experience.

A famous jurist once said to his law student: "In your practice of law beware of the attorney with a small library, he has it in his head." In the teaching of materia medica I would suggest a small but carefully classified list of drugs that shall be thoroughly studied and demonstrated. The most eloquent man in the world could not teach diagnosis except in the presence of disease; neither can the most scientific teacher of materia medica bring his instruction to a successful issue without the presence and the demonstration of his drug. The chemical and physiologic laboratory must be brought into requisition, and these kindred branches must be so interwoven in study of materia medica that the student can not tell where one begins and the other leaves off.

The teaching of this subject should be by means of didactic lectures, laboratory demonstrations and quizzes. As I believe it would be inexpedient, if not impossible, for a medical student to learn all of the drugs in our materia medica, it should be the duty of the teacher to select those which he deems most important and so classify them in accordance with their physiologic action that the whole field of medical therapeutics would be covered.

I believe that the importance of this classification can not be overestimated; unclassified knowledge is of little use and is soon forgotten. The drugs in each class should be arranged according to their therapeutic value, rather than in alphabetic order, and the same distinctions should be made in teaching of their physiologic action as is made in the study of synonyms in rhetoric. In this way, by the use of a comparatively few drugs, the student has a sufficient knowledge of the essentials of materia medica, to which he may add innumerable remedies, and be able to make the finer distinctions. This would do away with text-books on the subject, and in their place we would have reference books, as the student would be trained in library practice, which would serve him a good purpose in future years.

Laboratory instruction should consist, not only in studying the physical and chemical properties of drugs, by which the memory would be assisted by an actual acquaintance with them, but it should be carried into the physiologic laboratory; and pharmaco-dynamics should be so demonstrated on the lower animals as to make a lasting impression on the mind of the student.

There should be at least two hours a week for one college year devoted to recitations upon this subject, beside the instruction already mentioned. If, in addition to this, the course in physiology could be so arranged that a reasonable portion of the time be devoted to function, with a view to possible derangement and cures, and the work be made to harmonize with that of pharmacodynamics, the student of materia medica would be so interested that this branch would be studied because of his love for it rather than because it is an essential to graduation.

The study of pharmacy, materia medica and therapeutics can not be separated, and they must not be crowded into any one portion of the college course. From the day he enters the college until he passes his final examination the subjects of the cure of disease by remedial agents found in materia medica should ever be kept before the student. In the first year he should be introduced to the subject through pharmacy and chemistry. In the second year he should be interested in it through the subjects of physiology and physiologic chemistry. In the third it, with therapeutics, should be made the basis of the preliminary study of medicine; and in the senior year materia medica in the form of the prescription should be made the cap-sheaf of his study in medicine.

Chewing Pitch Good for the Teeth.—A Swedish physician, who has made a study of the subject, finds that the chewing of Burgundy pitch, which is common in some sections of that country, has a marked effect in preserving the teeth.—*Popular Mechanics.*

THE PLACE AND IMPORTANCE IN THE COLLEGE CURRICULUM OF THERAPEUTICS.*

HOBART AMORY HARE, M.D.
PROFESSOR OF THERAPEUTICS IN JEFFERSON MEDICAL COLLEGE.
PHILADELPHIA.

In discussing this question it is important that we should arrive at a definite conclusion as to what is meant by the terms materia medica and therapeutics. Sometimes these terms are used interchangeably and sometimes materia medica is used to designate the study of the medicinal substances themselves; their derivation, active principles and pharmaceutic preparations. This, I believe, to be the more modern use of the term "materia medica," while therapeutics deals with the practical application of the drugs to the relief or cure of disease, and should, in my opinion, include the study of the *physiologic action, or pharmacology, of the remedies* under consideration. In expressing my views as to the best means by which students are to be taught these important subjects, I may perhaps be pardoned if, for the sake of brevity, I describe the course which I have arranged for the students attending the Jefferson Medical College, in which institution I have charge of the subjects under discussion. And it is needless to say that I believe this to be the proper way of teaching materia medica and therapeutics or I would not have it so carried out.

THE PLANS OF THE FRESHMAN YEAR.

In the first year the student has one recitation and me *lecture a week in which he is taught the derivation* f the more common drugs; their official names; the oses of the preparations commonly employed; the predominant symptoms of poisoning by the common poisons and the antidotes for the same, and in addition, for six weeks of the term, he receives instruction in the pharmacy laboratory, the class being divided into sections so as to allow of individual teaching. In this laboratory each student has the opportunity of handling crude drugs, and he also is taught how to prepare all of the official preparations of the United States Pharmacopeia. I do not mean by this that he prepares all of them, but that he prepares, under the direction of competent demonstrators, a syrup, a tincture, a fluid extract, etc., taking one individual preparation as a type of a class; this course being designed not only to familiarize him with the crude drug and official product, but also to give him a clear conception of the difference between the various *pharmaceutic* preparations and to give him information which will prevent him from writing prescriptions which contain chemical and pharmaceutic incompatibilities. At the end of this course he has a practical laboratory examination covering his work in the laboratory, the mark in which counts a certain number of points, and he also is examined on the ground covered by the lectures and recitations which he has had during the year.

THE SOPHOMORE AND JUNIOR YEARS.

During the second and third years the student attends the lectures on general therapeutics, and is examined at the end of the third year on this course. These lectures consist in a description of the physiologic action and therapeutic application of the various remedies. The study of the physiologic action of the drug is not carried on separately from its therapeutic effect, but the practical application of our knowledge of its physiologic action to the pathologic condition present is carefully discussed. In this way I believe that it is much easier for the student to gain knowledge, both as to physiologic action and therapeutic application, than when these two subjects are considered separately. At the end of the third year an examination is held on the course just named. During the third and fourth years the student attends twice a week a general medical clinic, in which I devote special attention to diagnosis and the practical application of therapeutics. This clinic is not only illustrated by a very large number of cases in clinical medicine but its interest is also largely increased by the use of a powerful stereopticon, by means of which prescriptions, showing how certain drugs can be advantageously combined in the treatment of a malady, are thrown upon the screen without the room being darkened. This lantern is also used for the purpose of throwing pictures on the screen which illustrate cases of a similar character which have been brought before the class in previous years, so that instead of one case the lantern often permits me to show as many as six cases in addition to the actual living subject which is present. This lantern also permits me to throw on the screen colored pictures showing pathologic changes and diagrams illustrating physical signs. These pathologic illustrations are often of value, not only for the purpose of impressing on the student how drugs may do good, but equally important for impressing upon his mind that in certain conditions drugs can be of no value whatever so far as the pathologic state is concerned. Thus, if the student is shown a *lung which has undergone croupous consolidation, it is* not difficult to impress on his mind that the employment of chlorid of ammonium as an expectorant under such circumstances is useless, since it can in no way influence the process of resolution. On the other hand, it impresses on the mind the fact that chlorid of ammonium may aid in expectoration in the later stages of resolution by aiding in the expulsion and relieving the congestion of an inflamed bronchial mucous membrane. In the teaching of therapeutics it is as important, in my mind, to teach the student when not to employ drugs as it is to teach him when to employ them. Too often a young graduate leaves his alma mater with the idea that properly applied remedies can cure everything. Under these circumstances he speedily meets with disappointment, and is often driven to the other extreme, in which he becomes a therapeutic unbeliever, when *in reality had he* been properly taught he would have become a rational *and safe therapeutist.*

THE SENIOR YEAR.

During the fourth year the senior student not only attends the clinic just mentioned, but also hears lectures *once every alternate week* on special therapeutics, including such subjects as hydrotherapy, electro-therapy, climatology, mineral springs, serum-therapy, etc. In the other week he attends a therapeutic conference in which he is quizzed on the treatment of real or supposititious cases and is required to write prescriptions on the blackboard embodying his therapeutic views, which prescriptions are then *criticised as to their construction and* therapeutics before the class.

This course is the result of some eighteen years' experience in the treatment of this subject, and I believe that it meets the needs of the student. As an illustration of what the course is intended to teach I may be permitted to quote two paragraphs which are found on the fly-leaf of the ninth edition of my text-book of "Practical Therapeutics":

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

"When called to guide a patient through an illness, the physician should be constantly a watchman, and a therapeutist only when necessity arises."

"A good physician is one who, having pure drugs, knows when to use them, how to use them and, equally important, when not to use them."

DISCUSSION

ON PAPERS OF DRS. HILL AND HARE.

Dr. Lefevre, Cincinnati—I approve of the remarks of the first speaker, with regard to the relative neglect of therapeutics by medical schools in general and by the profession. I have been connected in a teaching capacity with this particular branch for a number of years. After several years I adopted a plan which was practically that outlined by the last speaker. In the first year I have the students devote their time to the study of the physical qualities and properties of drugs and their combinations, but nothing at all about the physiologic effects or therapeutic properties or applications. In the second year they are taught the physiologic action and in the latter half of the second year pharmacology is taken up, and a classification made of several types of drugs on a pharmacologic basis. Quizzes are carried on in connection with the lectures. In the third year instruction is conducted by didactic lectures, quizzes and demonstrations of the clinical action of drugs. Conferences are held, devoted to the consideration of remedies acting on the heart, or on the nervous system, or other special organs. Notice is given in advance so that the students come prepared for these discussions. In the lectures during this part of the course the general properties of the drugs and their applications to certain diseased conditions are reviewed, the different drugs being presented in the order of their relative value in the treatment of the condition under consideration. In the fourth year clinical conferences are given to the graduates. Certain cases are assigned for study and placed on the bulletin board, so that the students may prepare themselves to discuss these cases at the conference. Special instruction is given also in the fourth year, in electrotherapeutics, balneology, the effects of heat and cold and other non-pharmacologic topics, by special lectures and demonstrations. This whole course is so arranged and conducted that the student may gain practical knowledge of the subject, in addition to the usual theoretical knowledge.

I wish to allude to the uselessness of the questions asked by the medical examining boards. I have made a list of a number of such questions given by medical boards of various states to candidates for license to practice medicine. For instance: the uses of pumpkin seeds had been asked twenty times, and there were others equally useless, about minor drugs. It would seem that they chose the useless articles of the pharmacopeia rather than the main drugs and their therapeutic applications. With regard to the subject of classification of drugs, I agree with Dr. Hill, and I would follow the plan of grouping them according to their application to certain disturbed functions. This can only be done with a student who has a knowledge of the physiologic action of the drug. With advanced students such a classification is of much service in studying materia medica. With very few exceptions I have adopted the methods outlined by the preceding speakers with their classes, and I think if carried out further they will lead to more definite teaching and better knowledge of the subject.

Dr. A. W. Baer, Chicago—In the hospitals and dispensaries, the student goes through all the clinical rooms except one—the drug room. It is within the province of teachers to render great service to their students by pointing out to them the great benefit to be derived from spending at least part of their summer vacations in a pharmacy. Any young man, with the necessary acquaintance, can easily get a situation in one where he can learn more in three months, regarding the properties of drugs and their combinations, than he can learn in a medical college in two terms of four months each.

Dr. Frances Dickinson, Chicago—In the school with which I am connected it is the practice to postpone the teaching of the physiologic action of drugs until the third year. Such teaching requires special apparatus for demonstration, and few schools have the necessary equipment and facilities for teaching and demonstrating the action of drugs from the physiologic standpoint, or their physical effects. With such appliances the student can grasp the facts of the science better and they are more firmly impressed on his mind, when the methods of study used in the physiologic laboratory are followed, rather than by attempting to memorize the subject directly from books. With regard to the classification of drugs the arrangement according to their physiologic action has a scientific basis. It is advisable to make out a list of the drugs of special importance to be taught thoroughly in the curriculum, and then, just before the men go before the state boards, to give several evenings to a review of the drugs of minor importance so that they will be thoroughly prepared. The study of pathology is dead at present; it should be connected more closely and logically with the therapeutic use of drugs from chemical and physical action standpoints.

Dr. William J. Robinson, New York—There is one point which does not seem to have been sufficiently emphasized. We all recognize the importance of therapeutics, but we do not realize that our own neglect of it has led to the growth and development of sects and quackery, such as Eddyism and osteopathy. Very often men who are empiric are very successful in treating minor ailments, which are less successfully treated by the higher scientific practitioners. Some physicians who are well up in pathology may not be good practitioners; they are too apt to neglect, or consider as beneath their dignity, the trifling ailments of their patients, which other physicians of less scientific attainment treat successfully. If irregular physicians get their patients from us it is due to our own neglect of therapeutics of these minor ailments. I endorse the views of Dr. Hare as to the questionable usefulness of an attempt at classification of remedies. Take up a text-book that has such a classification and the failure is at once evident: acetic acid, for instance, is classed as a cardiac depressant, etc. Drugs can not be classified therapeutically without being subject to criticism; in fact, they might almost as well be arranged alphabetically for convenience of reference; of course, drugs very closely related, like the solanaceæ, or digitalis and strophanthus, should be classified together.

With regard to the character of the questions asked by medical state boards, I once asked an examiner why he asked questions about drugs that were of so little importance, who replied: "Of course, on the principal drugs the student would be well prepared and there would not be enough questions to go around. We would be obliged to ask the same questions over and over again, so we have to take the less known drugs for examination." This, at least, gives some explanation of their course in asking apparently useless questions. I approve the suggestion of the last speaker with regard to the value of actual experience in drug stores for medical students. It will not improve him as a diagnostician, but will make him a better prescriber; one less likely to combine incompatible chemicals, and it would acquaint him with drugs as they are used at present in the treatment of disease. A short apprenticeship of about three months behind the prescription counter would be sufficient.

Dr. Eli H. Long, Buffalo—It is a hopeful sign that those engaged in teaching the subjects of materia medica and therapeutics should meet and compare their methods. I agree in the main with Dr. Hill and think the course outlined by him admirable. It is one that I can endorse from my own experience. As regards the matter of small attention being paid to therapeutics, the remedy for this state of affairs lies in our own hands. The time is very rapidly approaching when the physician and the surgeon will recognize the usefulness of drugs to a far greater degree than they do at present.

In my own course, materia medica is taught in the second year as a laboratory subject; the students are seated at tables and given a limited number of the most important drugs for thorough study under the direction of the lecturer, their constituents, properties and general uses being learned in this way. The pharmacal laboratory course during the same semester includes experimental incompatibility. During the same year a recitation course introduces therapeutics and a course in experimental pharmacology familiarizes the student with the positive action of the important drugs. At the beginning of his third year the student knows a great deal of chemistry, anatomy and physiology and some pathology. He is in possession of facts from which he can draw practical deductions as to the use of remedies in practice. In aiding the student to do this, I do not teach by lecturing, but by conferences with the students. Assuming that they know their materia medica and physiology, I review with them the pathologic conditions present in disease, and help them to reason out the application of drugs to suit such conditions. The importance of teaching the student to think and reason out for himself can not be too highly estimated. He is thus taught to do before graduation what he would otherwise have to learn in his first years of practice. I am glad to know that prescription work is now emphasized. I teach practical prescription writing in the fourth year. The students write prescriptions for clinical and hypothetical cases, their work being then subject to criticism and discussion by the class.

Dr. Horatio C. Wood, Jr., Philadelphia—It is a point of considerable importance in teaching whether we attempt a classification or not. Because we can not classify drugs exactly scientifically, we should not therefore abandon it entirely. If we can not at once give a complete classification of remedies from a therapeutic standpoint, it is no reason for not trying to do so. If we do not make any attempt, it absolutely puts an end to progress. The classification used in botany to-day is different from that which prevailed a few years ago, and may undergo other changes. The classification of plants according to the color of their flowers would be just as scientific as the alphabetic arrangement of drugs. The man who adopts an alphabetic classification of remedies is not contributing to the advance in therapeutics. For illustration: we know that digitalis and strophanthus have a similar action on the heart, and it is of great assistance to the student if they are grouped together. If, on the contrary, he studied digitalis early in the year and several months later he came to strophanthus, in the alphabetical arrangement of drugs, he might not succeed in establishing their relation in his mind, and their resemblance might be overlooked. Classification of some kind is of great assistance to the student, and the therapeutic or physiologic method will aid him in keeping the common properties of remedies of the same group in his mind, and will enable him to retain them for his future needs in practice.

Dr. Henry Slack, Lagrange, Ga.—I agree thoroughly with Dr. Hill. About five years ago I made a tour through a number of medical schools to observe their method of teaching therapeutics, and from what I observed I came to the conclusion that the profession was drifting toward therapeutic nihilism or empiricism. Teaching has improved somewhat since, but it is not yet all it should be. One of the weakest points in teaching is the dispensary work. The student gets a large portion of his practical knowledge in the use of drugs from his experience in the dispensaries, where the method is to use stock preparations which are distinguished by numbers or letters. For instance, a physician came to New York from another state and prescribed a mixture under the title of "M. G. A." The pharmacist could not fill it and the physician had to search in his notes for nearly fifteen minutes to find out himself what the composition of "M. G. A." was.

Dr. Solomon Solis-Cohen, Philadelphia—I did not hear the papers, but they are on a subject on which I entertain very decided convictions. There can be no doubt that the reason why the patent medicine man has such success and why so many proprietary preparations are used is that the average medical student when he leaves college has not learned how to prescribe. He may go out with the idea that drugs are to be given according to some mysterious principle known only to his teacher, or as a therapeutic nihilist. To remedy this but one thing is necessary: it is to make the medical student think out the prescriptions in his college course and learn to write them intelligently before he gets his diploma. Let him frame a prescription for an actual patient in the presence of his teacher, who can show him where he is wrong and wherein he is right and explain the reason; he will then soon learn the correct principles of drug prescribing. Just as in any other problem, however, the condition must be stated and understood before the solution is possible. Anatomy, physiology, pathology, etiology and diagnosis, on the one hand, and chemistry, physics, materia medica and pharmacodynamics on the other hand must be known before therapeutics can be studied as the keystone of the medical arch. No matter how much a man may know of abstract science, the patient comes to the physician as to a "healer," and the latter's accurate knowledge of pathology would have very little value if he could not assist or relieve the sufferer. The sick man is not merely a unit in a column of statistics, but a living, sentient, human being and is so to be managed. I tell my students that the clinical diagnosis comes first, but it is not sufficient merely to call a morbid process by a name. One must also make the pathologic diagnosis; that is, to determine the special morbid changes that are going on in an individual patient at the time of examination and forecast their probable course. Then the etiologic diagnosis is to be made—the causation originally, and the causes now active or likely to become active are to be sought for. After this comes the therapeutic diagnosis: Can the causes be removed or overcome? What is the evolution of the disease and can it safely be left to itself, or do dangers threaten from which the patient should be guarded? If dangers threaten in the course of normal evolution, shall we interfere, and if we determine to interfere, for what purpose and in what direction shall the interference be made? Then, we have to decide by what means to interfere, considering not only the pharmaceutic agents at our command, but also the physical and psychic influences through the use of which we can best attain the definite object we have in view. Now, unless in previous teaching the remedies have been classified, the student knows not where to look in his mind for the name of the particular drug, or measure, or means, that will do what he has decided ought to be done. The kind of teaching that will bring him up to that point must come, so far as concerns materia medica, from teaching a few drugs exhaustively in connection with physiology and functional pathology, and others in subordination to the main examples. We must not, however, neglect similar teaching of physical measures or fail to take account of the mental processes. The time has come for the profession to take out of the hands of the quack these potent agents. Suggestion as well as the more tangible remedial measures has its legitimate use.

Dr. Hill, in closing—In regard to the classification of drugs from a physiologic standpoint, while I realize that a perfect classification in this way is impossible, still we may group the principal ones satisfactorily and the balance we may put under the head of alteratives. I have never taught a student with a view of his passing state boards or final examinations, but I believe a student who is well grounded need fear no examinations. A man who knows all about a few things and a little about all things is regarded as an educated man. The same rule is applicable to the study of drugs. A familiarity with all drugs is desirable, but a working knowledge of one or more principal drugs of each physiologic class is essential. Grouping the drugs of minor importance around the principal ones not only facilitates the memorizing of them, but also enables the student to make practical application of the knowledge he possesses. I believe the sophomore year is the place for pharmacodynamics, as the student is then studying physiology and pathology. If the curriculum can be so arranged that a portion of the time given to pathology be devoted to functional pathology and the work in this branch be made supplemental to physiology and pharmacodynamics, the student, when he reaches the junior year, will be ready to take up the application of drugs to disease. This work I do in a systematic way in the first semester of the junior year, the second semester being to class conferences in hypothetical cases. In the fourth year I treat applied therapeutics in the hospital clinics. Cases are given individual students who write complete histories and descriptions of existing pathologic condition (organic or functional). Treatment is outlined by him and prescriptions written, then the patient and history are brought before the class for discussion and criticism. In this work we aim to treat the existing conditions—or, as some one has said: "to treat the patient."

MENTAL THERAPEUTICS AND THE NEED OF PSYCHOLOGY IN THE MEDICAL CURRICULUM.*

HOWELL T. PERSHING, M.Sc., M.D.
Professor of Nervous and Mental Diseases in the University of Denver.
DENVER, COLO.

> Every illness is a factor simple or complex, which is multiplied by a second factor, invariably complex—the individual who is suffering from it. The doctor who does not read you to the bottom is ignorant of essentials. To me the ideal doctor would be a man endowed with profound knowledge of life and of the soul, intuitively divining any suffering of whatever kind, and restoring peace by his mere presence. Such a doctor is possible.—*Amiel's Journal.*

Physicians need no argument to show that purely physical processes may cause profound mental changes. Every case of lesion of the brain, every delirious fever patient, every exhilarated banqueter, furnishes a fresh illustration of the fact. The converse proposition, that purely mental processes may cause profound physical changes, still excites a tendency to doubt or wonder, but it is just as true and special instances are just as familiar. The blanched face, chattering teeth, shaking limbs and weak, irregular heart of a person who is merely frightened; the nausea, cold extremities, arrested digestion, prostration and loss of weight in a previously healthy person who has merely received bad news by telegram: the manifestation of muscular energy in response to an idea, which occurs in every voluntary action; all these are constantly recurring proofs which might be multiplied almost indefinitely.

Our modern knowledge of the brain goes far toward a satisfactory explanation of this mutual action of body on mind and mind on body. Every sensitive part of the body has its sensory area in the cerebral cortex; all the voluntary motions are represented in regular order in the motor keyboard of the Rolandic region. Changes in the body modify the sensory currents which are constantly streaming into the cortical centers and so modify sensations which are the raw material of all forms of consciousness. Every emotion, every thought causes nerve currents to pass from one group of cortical centers to another and ultimately to muscles, viscera and all other tissues. Every thought about an organ of which one is conscious excites the corresponding sensory and motor centers and through them modifies the function of the organ. Emotional disturbances cause a particularly energetic disturbance of the thoracic and abdominal viscera whether these organs are thought about or not.

These generalizations are familiar enough now, but they have not improved medical practice as such great physiologic truths ought to improve it. The majority of us treat patients as machines out of order, to be repaired by purely mechanical, physical or chemical remedies. Yet, with only insignificant exceptions, a physician must always make a strong mental impression on his patient. And if such impressions exert a physical action for good or ill comparable to that of powerful drugs or of electricity, then surely it is incumbent on us to make our knowledge of mental processes and their effects as accurate, full and systematic as possible. It is the object of this paper to give specific illustrations of the need of psychologic knowledge in the practice of medicine in general. Insanity will not be included, for, strange to say, the great problems of mental disease are physical rather than psychologic problems. Hypnotism will also be omitted from the discussion, as I do not regard it as an eligible therapeutic agency in any but exceedingly rare cases.

An Illustrative Case.—Some years ago a young Russian Jew came to Denver from one of the hospitals in Philadelphia, armed with a big box of creosote pills, which were to aid him in a desperate fight to escape death from consumption. Less than a year before, while in apparently robust health, he had fallen into the water and was almost drowned. A violent cough began the same day and grew steadily worse, often being accompanied by vomiting. After a time blood appeared in the sputum and hemoptysis became first a frequent and then an almost constant symptom. Latterly blood had appeared in the urine also. His weight had fallen from 205 to 155 pounds.

He appeared at the Dispensary of the University of Denver, coughing incessantly and panting for breath, so that it seemed impossible for him to talk; his handkerchief was constantly held to his mouth and was covered with blood stains. The students thought he might die at any moment.

But a thorough physical examination revealed nothing abnormal in the chest, so he was sent to me with the expectation that I would find a grave organic lesion of the central nervous system. I found right hemianesthesia, amblyopia of the right eye, complete loss of hearing, smell and taste on the right side, aphonia and some weakness of the right arm and leg, the whole combination being perfectly typical of hysteria. The history contained many points strongly indicative of an hysteric origin of all the symptoms. The blood on the handkerchief was genuine, but pale and thin, as though much diluted by saliva. The urine passed then was clear and contained no albumin.

The diagnosis of hysteria was made at the first interview and, in the presence of a number of students, a most impressive statement was made that the true nature of the disease had now been discovered and that he would be cured very quickly if he would only do exactly as he was told. His respiration was over sixty per minute and the first thing was to drill him into breathing slowly. Then, after some electrical applications, made solely for psychic effect, he was sent to his lodging with the positive assurance that slow breathing would entirely stop the coughing and spitting of blood and that he would sleep soundly that night. To insure fulfilment of the latter prediction, he was given ten grains of chloral to take on going to bed. Other drugs were purposely omitted.

The patient slept that night and returned next day in an exuberant state of happiness; the dyspnea and cough were practically gone, there was no blood in the saliva and the voice was much stronger. St. Luke's Hospital admitted him as a charity patient and on full feeding and continued encouragement he gained very rapidly in weight and strength. Some days after admission he insisted on going out to beg some money and on returning unsuccessful was tearful and apparently greatly depressed. The next morning the house physician observed that there was blood in the sputum and also in the urine. This disappeared during the day but was noted again the following morning. The specimen of urine furnished me each morning was of a clear crimson color, without sediment, contained albumin, responded to the guaiac test for blood and under the microscope showed many red blood cells. With the blood cells was a considerable number of squamous epithelial cells which I supposed to be from the bladder. Only here and there was a columnar epithelial cell observed. Blood did not appear again in either urine or saliva and the patient made very rapid progress, about 25 pounds being gained in a few weeks.

He then left my care, saying he must return to his family in Philadelphia. For some reason, probably to get a little money from me, he was lying, and instead of leaving Denver, went to work in a livery stable. Some days later, while currying a horse, he sank to the ground and was found to be paralyzed on the right side. Speech was retained and he cried a great deal. Two weeks after this the physician who had examined his chest happened to find him in a lodging house and told me of his condition, remarking that whatever else might be hysteric, this hemiplegia was organic. Some students hunted the man up and brought him to my office. I found the right arm and leg in rigid extension; the foot was dragged, not swung; the face and tongue were not involved; right hemianesthesia had returned; in short, the paralysis was clearly hysteric.

---

* Read before the Colorado State Medical Society, June, 1902.

After some reproaches I promised to cure him again, at 11 o'clock the next day. The students saw to it that he kept his appointment and after some electrical stimulation of the affected muscles, followed by manipulation and exercise of each joint, used only to restore confidence, he used both the leg and arm very well, only a slight awkwardness remaining. I never saw him after this, but have no doubt that he relapsed before long.

This case is, of course, a very unusual one, but it is highly instructive on account of the prompt disappearance of such alarming symptoms under a treatment intentionally limited to mental impressions[†]. All cases of hysteria are like it in having mental perversions for their exciting cause and in being absolutely defiant of any treatment which does not, intentionally or accidentally, include the right mental effect. Cases of hysteria, moreover, are common in all branches of practice. They come to the practitioner of internal medicine disguised as grave gastric or intestinal disorders, as heart disease, as epilepsy, apoplexy or what not. To the surgeon they may appear disguised as an exquisitely painful inflammation of a joint, as a foreign body in the esophagus, as appendicitis or as a neuralgia perhaps so intense as to demand amputation for its relief. The gynecologist sees the symptoms of organic pelvic disease closely simulated by hysteria. The oculist sees hysteric amblyopia, spasm of the internal recti, often mistaken for insufficiency of the external recti, spasm of the orbicularis simulating ptosis, and so on. The laryngologist deals with hysteric aphonia, hysteric cough and hysteric laryngeal spasms. Even the dermatologist has his cases of pure hysteria.

But, vast as the field of hysteria is, it is by no means the only disease in which psychic methods are necessary. Many cases of neurasthenia, although they seem to be caused by exhausting physical influences, are in reality mainly due to a persistent depressing idea. Worrying about imaginary disease may be more harmful than the effects of the real disease. Many a man carries a mental burden for months or years because he has an occasional seminal emission or because he has discovered a little mucus at the meatus or the normal epididymis, or the veins of the spermatic cord, or that the left testicle hangs lower than the right. That a nervous woman's mind is often fixed upon her pelvic organs, to her great detriment, is well known to every physician. Similar false ideas in regard to syphilis, heart disease, tumors and the effect of injuries are far from being rare. A morbid idea of this kind constitutes a mental traumatism which is often the most important fact in the case, and no treatment can succeed unless it includes persistent systematic effort to eradicate the false notion and to replace the state of emotional depression by one of serenity and confidence.

Digestive derangements are of the greatest importance in general practice if only on account of their frequency. It must be admitted that great additions have been made to the knowledge of normal and pathologic digestion and much greater precision in diagnosis and treatment attained. Still the profession is very far from recognizing the full importance of mental factors in the etiology of functional digestive disorders. Excessive mental work, worry and depressing emotions are the primary causes of a very large proportion, perhaps of a majority, of the cases of disturbed digestion; yet these causes are commonly ignored and the remedy sought in pepsin or hydrochloric acid or a severe restriction of diet. These remedies, although suggested by conditions actually present, fail to remove the real cause, unless by accident, and they often do harm. In the course of evolution the whole process of digestion has become excessively sensitive to attention and especially to the idea that the food is in any way wrong. Close, anxious attention to one's diet is certain to impair digestion whether the foods selected be in themselves good or bad. The physician must, of course, have due regard to the chemistry of digestion and restrict the diet in certain cases, but he must also understand the relation of digestion to the functions of the nervous system; in short, he must know the whole man.

Much might be said of the psychic factors in the formation and correction of bad habits. See, for instance, what is accomplished in the "Keeley cure" simply by following each indulgence in whisky with a hypodermic of apomorphia, the patient supposing it to be his usual tonic. Intense nausea and vomiting thus become associated with the mere thought of taking a drink and powerfully reinforce the desire to abstain.

In nervous patients we frequently find an emotional condition which causes over-contraction of the voluntary muscles and embarrassed, rapid respiration. This is an important source of distress and exhaustion and must be obviated by teaching the patient not to attempt to hold the nervousness in, but to relax the muscles and to breathe freely and slowly. Bodily relaxation and easy breathing strongly favor mental serenity; indeed, they are quite incompatible with intense emotion, and on this account they will infallibly prevent any form of hysteric paroxysm if the patient can only be induced to put them into practice in the incipient stage of the attack.

In treating any class of diseases in which there is a hysteric or neurasthenic element the physician is often embarrassed by the patient's statement that the medicine disagrees, although it has been carefully chosen and proportioned to the needs of the individual case. In the great majority of such instances the supposed disagreement is due solely to suggestion. The patient is liable to bad sensations and at some previous time has felt badly when taking a drug similar in some respect to the one now prescribed. Consequently any disagreeable feeling, whether evoked by expectant attention or occurring accidentally, is attributed to the new prescription and the physician is greeted with something like this: "Doctor, I had to stop taking that medicine; it nearly killed me. I ought to have told you that I never could take strychnia," etc. This is often a critical point in the management of the case. If the doctor innocently changes the prescription he will probably have to change again and again until the patient has a long row of boxes or bottles, each nearly full, on which he gazes, regretting the money he has spent for them and meditating upon the doctor's strange failure to understand his case. Instead of changing let the physician explain that the prescription is exactly right, that the apparent disagreement was due to suggestion and that persistence in the right course will bring success. But, as an essential corollary to this proposition, let the prescription for a new patient be a perfectly safe one and sufficient to last only a short time, so that it will all have been used when a change is desirable. The ease with which the physician, as well as the patient, may form a fallacious estimate of the good or bad qualities of drugs is apparent.

[†] For a discussion of hysterical hemoptysis and hematuria, see Gilles de la Tourette, Traité de l'Hystérie, vol. iii, p. 221 et seq., and p. 380; also Loewenfeld, Neurasthenie and Hysterie, p. 418 and p. 445.

In infectious diseases, in organic affections in general and in surgical cases, the patient's mental processes count for comparatively little so far as recovery is concerned, yet even here they are of considerable importance. One of the ablest surgeons I have known had the same effect on many of his patients as on the students at examination time; they dreaded his visits and were in a state akin to stage fright as he made his daily rounds. It is not difficult to believe that certain patients, barely able, under the most favorable circumstances, to recover from an operation might have the scale turned the wrong way by this adverse influence. This particular man had great talents and acquisitions to make him successful. To one of merely average attainments his manner would have been an insurmountable barrier to success. And, on the other hand, we all know physicians of less than average knowledge and skill who nevertheless succeed admirably in acquiring and holding practice because they have the knack of impressing favorably a large class of patients.

But I do not wish to push the argument too far. It would be a grave mistake to rely mainly on mental influences in the great majority of medical cases. This is the mistake made by the Eddyites, often with tragic results. The proposition I wish to lay down is that in some very important cases the mental influence exerted by the physician is the only treatment that will succeed or is required, while in others it is an essential part of the treatment and in all is well worth taking into account as affecting both the patient's welfare and the physician's personal success.

It is no injustice to our profession to say that as a whole it has not studied the human mind sufficiently to meet the indications of everyday practice. The study of the body and the fight against the physical, chemical and parasitic causes of disease has been so engrossing that ignorance of the mind and the part it plays in disease could, perhaps, for the time being, be excused. But this ignorance will no longer be winked at. Agents so powerful for good or evil as suggestion and emotion can not be abandoned to fanatics and charlatans, nor will it be sufficient for an honorable profession to use them empirically. They must be skilfully employed on scientific principles for the good of the patient, not to deceive but to undeceive, not to make him wonder in weak-minded credulity but to strengthen him in rational self-reliance and bring him into a state of stable mental equilibrium.

To this end medical schools will in the future teach psychology as a fundamental part of the curriculum, just as they now teach physiology. This psychology will not be metaphysical, but a scientific description with, as far as possible, an explanation of normal and morbid mental processes and their bodily consequences. Sensation, perception, memory, association, emotions, will, hysteria, hypnotism, etc., must be studied in the light of all that is known of the structure and functions of the brain with clinical illustrations of the practical application of the knowledge gained to medicine.

Convinced of the importance of this subject, I have, during the past year, given to the medical students of the University of Denver a course of lectures on psychology in its relation to the practice of medicine, and the trustees have made it an essential part of the course. I believe that at present our school is a pioneer in giving systematic, although very elementary instruction in this field, but I predict that in a few years all schools will furnish more elaborate courses of the same kind.

Evolution of the Army Medical Department.—In his presidential address before the Association of Military Surgeons of the United States, Lieut.-Col. John Van R. Hoff discussed "The Broader Mission of Our Association." In the course of the address he said: "To-day the attention of our legislators is being directed toward the nationalizing of our state forces. Are the medical departments of these ready to assimilate? Have they reached the standard set for them by our honored founder in his memorable address? Some of our state guards have medical departments that leave little to be desired, but how many? I find by references to the latest returns that the organized militia numbers 115,749, of which 902 pertains to the medical department, including hospital and ambulance corps, about 0.8 per cent., less than one-half of what it should be for the most advanced line of assistance, leaving entirely out of consideration everything from there back to the base hospital, all of which would require not less than six times the total number of men now in the medical departments of the state forces. Are the medical departments of all states organized on identical lines? Are their medical officers members of a distinct corps? Or do they in some states yet linger, superfluous appendages to the regimental commander, to be made or broken at his whim? And as to equipment—is that uniform? Instruction—is that the same? Requisitions, reports, returns, regulations—do they correspond? Turning to the regular establishments, the association here also has a mission. It must demand of their personnel, both commissioned and enlisted, the highest degree of efficiency; it must see that their organization and equipment are as perfect, if not more perfect, than those of any other nation; it must provide a means, through our medical schools, for the dissemination of a knowledge of military sanitation in the profession at large, so that every physician will know something of the work of the medical officer. One of its most important duties is that a public medical school is established in which shall be educated those who are to become members of the three public medical services. Such a school should be organized in this city in connection with a great military hospital. To it should be nominated medical cadets exactly as are cadets to West Point or Annapolis. Here the enlisted force for the Hospital Corps should receive preliminary training for their important duties. In connection with the hospital should be a training school for women nurses for duty at fixed hospitals, and here special courses could be arranged for medical officers of the national guard. What a wonderful influence for good would such an institution develop! And last, but not least, the association must formulate plans by which private aid may be made to supplement, not supersede, the public service in time of war or other stress. But beyond these things, important as they are, the association offers to the military humanitarians of the world an opportunity to meet on common ground and co-operate in formulating methods for the mitigation of what must always be 'the horrors of war.' We see the beginning of this to-day in the presence of distinguished representatives of the medical department of foreign armies, gathered from all quarters of the globe, and may we not hope that through them and their successors the good influences of this association will be extended to the uttermost parts of the earth? Originated by civil practitioners to improve the efficiency of the medical department of the state forces, year by year the association has broadened its lines until it embraces in its membership not only the medical officers—past and present—of the national guard and volunteers, but of the army, the navy and marine-hospital service as well. Our doors are now opened to the medical officers of the armies of all nations."

MEDICAL SCHOOLS IN THE UNITED STATES.

Below is given a brief description of every college in the United States that is legally chartered to confer the degree of doctor of medicine and whose diploma is recognized by at least one state licensing board. The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law. The order in which the colleges are placed is according to date of organization, grouped in cities. The information given is, as a rule, obtained from the catalogs and has been submitted to the dean of each school for his inspection and approval. Colleges which belong to the Southern Medical College Association or the Association of American Medical Colleges have requirements for admission of students according to the rules of these Associations, unless their requirements are higher, in which case a statement is made to that effect. Extracts from these rules are given at the close of the list of colleges.

ALABAMA.

Alabama, population 1,828,697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College.

Mobile.

MEDICAL COLLEGE OF ALABAMA.—This is the Medical Department of the University of Alabama, and was organized in 1859. It is located in Mobile, a city of 38,469 inhabitants. The City Hospital furnishes free clinical material. The faculty consists of 9 professors and 17 lecturers, 26 in all. It is well equipped with buildings, laboratories, dispensary, etc. It is a member of the Southern Medical College Association. The course of study is graded and covers four years of six months each. The total fees for each of the first three years is $100; for the fourth year, $125. Board and lodging, $3.50 to $5 per week. The Dean is Dr. George E. Ketchum, Mobile, Ala. Total registration, 1901-1902, 136; number of graduates, 13. The thirty-seventh session will begin Oct. 7, 1902, and will close April, 1903.

Birmingham.

BIRMINGHAM MEDICAL COLLEGE.—This school was incorporated in 1894 and is situated in Birmingham, a manufacturing town of 38,415. The clinical advantages are good. The Hillman, St. Vincent's, Pratt and County hospitals are accessible to the students. The clinical, histological and pathological laboratories are well equipped. There are 12 professors and 8 lecturers; total, 20. The school is a member of the Southern Medical College Association. The course of instruction is a graded one and embraces four separate sessions of six months each. The fees are $75 for each of the first three years and $105 for the fourth. Good board can be obtained at from $12 to $20 per month. The Dean is Dr. B. L. Wyman, Birmingham. Number of students registered last session, 82; number of graduates, 8. Next session opens Oct. 1, 1902, and closes April 1, 1903.

ARKANSAS.

Arkansas, population 1,311,564, has one medical college.

Little Rock.

MEDICAL DEPARTMENT OF THE ARKANSAS UNIVERSITY.—This college is located at Little Rock, population 54,587. It was organized twenty-three years ago as the Arkansas Industrial University Medical Department. It is a charter member of the Association of American Medical Colleges. Hospital facilities are furnished by Logan H. Roots Memorial Hospital, St. Vincent's Infirmary and Pulaski County Hospital, the latter having a capacity of 200 beds. The teaching body consists of 23 besides assistants, Dr. F. L. French, Little Rock, being Secretary of the faculty. The fees are: Matriculation $5, paid but once; annual fees $60, and graduation $25. Board and lodging costs from $13 to $18 per month. Total number of students at last session, 220; graduates, 11. The next course of lectures begins Oct. 20, 1902, and ends April 11, 1903.

CALIFORNIA.

California, population 1,485,053, has eight medical colleges. Six are located in San Francisco, a city of 342,782 inhabitants. They are Cooper Medical College, Medical Department of the University of California, California Medical College, Hahnemann Medical College of the Pacific, West Coast Medical College, and the College of Physicians and Surgeons. The clinical facilities of San Francisco are good; board and lodging can be obtained for from $20 to $30 a month. The College of Medicine of the University of Southern California is situated in Los Angeles, population 102,479. Board and lodging can be obtained in that city for $4 a week and upwards. The Oakland College of Medicine and Surgery is in Oakland, a suburb of San Francisco.

San Francisco.

COOPER MEDICAL COLLEGE.—This school was organized in 1858, though its present name was not adopted until 1882. The faculty consists of 11 professors and 20 lecturers and demonstrators, 35 in all. Lane Hospital, adjoining the college; the City and County Hospital, containing 464 beds, and the college dispensary furnish clinical material. The requirements for admission are a certificate showing that applicant has passed the regular examination for admission to Stanford University or University of California, or other university having an equivalent standard, graduation from an accredited high school or academy, or graduation from California State Normal School. The college building supplies large laboratory and lecture-room facilities. The curriculum covers a graded course of four years of eight months each. Fees: First year, $115; second, $110; third, $100, and $125 for the fourth year. The Dean is Dr. Henry Gibbons, Jr., 920 Polk St., San Francisco. Total registration for 1901-2 was 214; graduates, 25. The present session opened Aug. 15, 1902, and will close April 28, 1903.

MEDICAL DEPARTMENT UNIVERSITY OF CALIFORNIA.—This department of the State University was organized in 1872, and has a faculty composed of 17 professors, 6 associates and lecturers, 41 instructors and assistants, a total of 64. The City and County Hospital, which admits students of this school not only to the clinics proper, but also to its wards for study, and the college dispensary furnish good clinical material. The senior class is divided into sections of six students each and bedside instruction is given them five days a week. Practical laboratory examinations are required of the students in the laboratories of the hospital, and practical obstetric demonstrations are given at the bedside. The building is commodious and furnishes good laboratory and lecture-room space. The course covers graded work for four years of eight months each. This school is a member of the Association of American Medical Colleges. The total fees for the first year are $115; second, $110; third, $100, and $125 for the four year. The Dean is Dr. Arnold A. D'Ancona, San Francisco. Total registration for 1901-2 was 151; graduates, 24. The thirtieth session opened Aug. 18, 1902, and will close May 18, 1903.

CALIFORNIA MEDICAL COLLEGE.—Eclectic. This school was organized in 1878. Its faculty includes 14 professors, 8 lecturers and 6 instructors, a total of 28. The clinical material is supplied by the Buena Vista and City and County hospitals. Applicants for admission not holding diploma or certificate are examined. The course has been extended to cover four years of eight months each. Total fees are about $110 for each of the first three years and $40 for the fourth year. The Dean is Dr. D. Maclean. Total registration for 1901-2 was 84; graduates, 6. The next session opens Oct. 6, 1902, and closes June 17, 1903.

HAHNEMANN MEDICAL COLLEGE OF THE PACIFIC.—Homeopathic. This was organized in 1884, and has a faculty of 17 professors, and 21 lecturers, instructors, etc., in all 38. The Pacific Homeopathic Polyclinic, the Homeopathic Sanatorium and the San Francisco Nursery for Homeless Children and Marie Kip Orphanage, accommodating, respectively, 45, 75 and 120 beds; Fabiola Hospital, and the City and County Hospital, furnish a clinical material for study. Matriculants must possess a knowledge of English composition, arithmetic, geography, history and Latin, as evidenced by certificate or examination. One year after entrance is permitted in which the student may prepare himself in Latin. The course includes four years of seven months each. Total fees for the first year, $150, and $100 for each of the other three years. The Dean is Dr. James W. Ward, 606 Sutter St. Total registration for 1901-2 was 45; graduates, 8. The twentieth session opened March 6, 1902, and will close Oct. 31, 1902.

COLLEGE OF PHYSICIANS AND SURGEONS OF SAN FRANCISCO.—This school was organized in 1896 and has a faculty of 24 professors and 26 associate professors and teachers. The hospital facilities consist of the City and County Hospital, where the college has 3 wards available for bedside instruction; the California General Hospital with 50 beds, owned and controlled by the college trustees, and St. Winifred Hospital with 50 beds, where clinical instruction is given in abdominal surgery and gynecology. The daily clinics at the new college building furnish abundant material of every description. Applicants for matriculation must show an equal amount of work done or pass a satisfactory examination in English, history and government, geography, physics, mathematics and Latin, grammar and translation. The college building recently completed is well supplied with laboratories and lecture rooms. This college now conducts a continuous course of medical instruction. Each year is divided into four quarters of three months each, and known as the autumn, winter, spring and summer quarters. Students may enter at the beginning of any quarter. Attendance on 12 quarters will be required and at least 45 months must elapse between the beginning of the first course and the time of graduation. Fees, $30 per quarter. The Dean is Dr. D. A. Hodghead, 1025 Sutter street. Registration for 1901 was 180, of these 41 graduated in medicine. The autumn quarter opened Sept. 2, 1902, and closes May, 1903.

WEST COAST MEDICAL COLLEGE.—This school is the successor of the Pacific Coast Regular College of Medicine. The Dean, Dr. C. W. W. von Tiedemann, 818 Howard St., writes that the enrolment for 1901-2 was 122, the course is five years, the degree of A.B. is required for entrance.

Oakland.

OAKLAND COLLEGE OF MEDICINE AND SURGERY.—This new school will open this fall. The Registrar is Dr. R. T. Stratton. The faculty numbers 21. Tuition is about $115 yearly. The session opens Sept. 15, 1902, and ends May 16, 1903.

Los Angeles.

College of Medicine, University of Southern California.—This school was organized in 1885, and has a faculty of 27 professors and 7 instructors, etc., 34 in all. The County Hospital, having 200 beds, and a college dispensary furnish clinical material. Applicants for admission are required to pass an examination in English, arithmetic, elementary algebra, physics and Latin equal to one year's work, unless they can show by certificate that they have covered that ground. The building is amply provided with laboratories and lecture rooms. A graded course, covering four years of thirty-two weeks each, is offered. The total fees for the first year are $145; second and third, $130 each, and $40 for the fourth year. The Dean is Dr. James H. McBride, Potomac Block, Los Angeles. Total registration for 1901-2 was 102; graduates, 14. The next session opens October 16, 1902, and closes June 10, 1903.

COLORADO.

Colorado, with a population of 539,700, has three medical colleges. Two of these are in Denver, which has a population of 133,859: Denver—Gross Medical College and Denver Homeopathic College; the other, the Colorado School of Medicine, is at Boulder (population 6150). The clinical facilities in Denver available to the two colleges are the Arapahoe County Hospital, which has a capacity of 225 beds; St. Joseph's Hospital, with 200 beds, and St. Luke's Hospital, with 75 beds. The Public Library contains 10,000 volumes on medicine. Board can be obtained in Denver for $5 a week and upward.

Denver.

The Denver and Gross College of Medicine.—This is the Medical Department of the University of Denver, and was organized this year by the union of the Gross Medical College (organized 1887) and the Denver College of Medicine (organized 1880). The clinical advantages are the college dispensary, the Arapahoe County Hospital, St. Luke's Hospital, St. Anthony's Hospital, St. Joseph's Hospital, National Jewish Hospital for Consumptives, Home for Dependent Children and the City Contagious Hospital and Mercy Sanitarium. The faculty is made up of 39 professors, 11 clinical and associate professors and 41 instructors, and other assistants, a total of 91. Its location is central and the buildings are well arranged for laboratory, dispensary and didactic work. The course is graded and covers four years of eight months. The college is a member of the Association of American Medical Colleges. Final examinations at the end of each year are held. Fees for the first year are $115. For the second year $116. Third year $101. Fourth year $126. Total registration 1901-2: Denver College of Medicine, 60; Gross Medical College, 73. Graduates Denver College of Medicine, 11; Gross Medical College, 24. The twenty-second session will begin Sept. 16, 1902, and close May 16, 1903. The Dean is Dr. G. Bonney.

Denver Homeopathic College.—This college, organized in 1894, besides the Arapahoe County Hospital, has exclusive privileges for clinical work in the Denver Homeopathic Hospital, the Haven and the Belle Lenox Nursery. The faculty numbers 23 professors and 9 lecturers and instructors, 32 in all. The requirements for admission are, "possession of a diploma from a literary college, university, an academy, a normal or high school; a first grade teacher's certificate, or a previous matriculation at some reputable literary or medical college." The course of study consists of four years of seven months each; monthly examinations are held in each subject. A five-year scholarship may be had for $300, payable in advance, otherwise the tuition is $100 a year; there is a matriculation fee of $5, payable once. The Dean is Dr. James P. Willard, Masonic Temple, Denver. Total registration for 1901-2 was 34; the number of graduates, 10. The ninth session begins Sept. 17, 1902, and will close April, 1903.

Boulder.

Colorado School of Medicine.—This is the Medical Department of the University of Colorado, and was opened in 1883. The University Hospital, under the control of the state, is equipped to accommodate 40 patients and furnishes free clinical material. Both hospital and dispensary clinics are offered and the sanatorium located in Boulder offers additional advantages in this line. The faculty embraces 15 professors and 10 lecturers and assistants, a total of 25. The laboratories are well equipped and commodious. A separate building is devoted to the study of anatomy and another one is used for medical work exclusively. A complete four-year course of study in a recognized high school, or its equivalent, is required for admission. This school is a member of the Association of American Medical Colleges. The work embraces a graded course of four years of nine months each. The tuition is $50 per year; there are no other fees. The Dean is Dr. Luman M. Giffin, Boulder. Total registration for 1901-2 was 63; graduates, 13. Twenty-first session begins Sept. 8, 1902, and closes June, 1903.

CONNECTICUT.

Connecticut has a population of 908,420, and contains one medical college.

New Haven.

Yale Medical School.—This is the Department of Medicine of Yale University, and is located in New Haven, a good railroad and manufacturing city of 115,000 people. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. In 1879 a new charter changed the name to the one now used, and in 1884 the Connecticut Medical Society, which from the granting of the first charter had taken an active part in its control, released itself from a further responsibility and the University authorities assumed full control. The clinical advantages are embraced under the New Haven Hospital, which contains 150 beds and is the general hospital for New Haven; the Springside Hospital, which is connected with the city almshouse, and the State Hospital for the Insane, which, with its 1800 patients, offers an opportunity for special instruction in insanity in addition to the clinics. Besides these, the University has just completed a $100,000 building for the dispensary service which offers good material for clinical teaching. The faculty embraces 13 professors, 5 lecturers, 12 instructors, and 22 assistants, a total of 51. The lecture rooms and laboratories are large and well equipped. Matriculants are admitted without examination, provided that they have received a degree in arts or sciences, that they present certificates showing that they have successfully prosecuted the subjects of the examination at some college, high school, academy, or preparatory school approved by the faculty, or that they have passed matriculation examinations equivalent to those required, at some approved professional school. This school is a member of the Association of American Medical Colleges. The course covers a four-year graded curriculum, eight months constituting a school year; the first two years the fundamental branches are studied, the third year is devoted to a systematic teaching of medicine, surgery, obstetrics and pharmacology, and in the fourth year clinical work, with medicine, surgery and the specialties, is presented. The fees are $150 each year: in the first year there are additional fees amounting to $18, and in the second, $8, and there is a graduation fee of $10. Board and lodging in New Haven can be obtained for $4.50 and upwards. The Dean is Dr. Herbert E. Smith, New Haven. During the session of 1901-2 there were 145 matriculants and 20 graduates. The eighty-ninth session opens Oct. 2, 1902, and closes June 24, 1903.

DISTRICT OF COLUMBIA.

Washington, population 278,718, offers to the student of medicine many advantages. The Army Medical Museum, the Museum of Hygiene, the National Museum, the library in the Surgeon-General's office, the Toner Medical Library and Museum of Hygiene, in all over 125,000 volumes on medicine, open to the medical student a most profitable field. The clinical advantages offered by the various hospitals are good. Owing to the many boarding houses and hotels, board and lodging can be had at extremely reasonable rates. The medical schools are four and are as follows:

Washington.

Medical School of Columbian University.—This school was organized in 1821 as the Medical Department of Columbian College, which in 1873 became Columbian University. Besides University Hospital, under the immediate control of the faculty and giving the students of this school exclusive clinical advantages, the Garfield Hospital, the Children's Hospital, Central Dispensary and Emergency Hospital, the Providence Hospital, the Lutheran Eye and Ear Infirmary, the Episcopal, Columbia and the St. Elizabeth's hospitals, all permit of abundant opportunity for clinics and clinical material. The faculty is composed of 29 professors, and 23 demonstrators and assistants, 52 in all. This school is a member of the Association of American Medical Colleges. The equipment and facilities for laboratory, didactic and clinical work are good. The completion of graded work covering the period of four years, eight months to the school year, is required; semi-annual examinations are held. Total fees for each year are $110. The Dean is Dr. E. A. de Schweinitz, 1325 H. St., N. W., Washington. New and enlarged buildings for both college and hospital will be completed by the opening of the next term. For the school year 1901-2 the total registration was 257; the graduates were 26. The eighty-first session begins Oct. 1, 1902, and closes June 1, 1903.

Georgetown University School of Medicine.—This school, organized in 1850, controls the Georgetown University Hospital, which affords excellent facilities for clinical teaching and ward classes. Clinics are also held for the benefit of the students in Providence Hospital, containing 300 beds; in the Children's Hospital, the Central Dispensary, Emergency Hospital and the Garfield Hospital. Attendance on clinical instruction is obligatory in the third and fourth years. The faculty contains 28 professors, 27 instructors and assistants, total 55. This school is a member of the Association of American Medical Colleges. The building is conveniently located and contains spacious and well-ventilated lecture rooms, laboratories and library; the laboratories are equipped with the most approved instruments and appliances. The complete course of study extends over four terms of eight months each. Examinations are held at the end of each session. The fees for the first, second and third years are $105 each, and for the last year, $100; a fee is charged for the material used in practical anatomy and operative surgery. The Dean is Dr. George M. Kober, 1600 T St. The total registration for the session 1901-2 was 130; graduates, 13. The next term opens Sept. 29, 1902, and ends May 31, 1903.

Howard University Medical Department.—This institution was organized in 1867 and "in conformity with the spirit of the organic law of the University, is open to all, without regard to sex or race, who are qualified by good moral character, proper age and suitable education." The removal of any racial distinction has been taken advantage of by colored students, who compose a majority of those in attendance, but a number of white students are also receiving instruction. The Freedmen's Hospital and Asylum is a general hospital of 300 beds. The faculty comprises 15 professors, and 10 lecturers and assistants, 25 in all. This college is a member of the Association of American Medical Colleges. Students are required to attend four courses of lectures in separate years of seven months each. The fees of each session are $80, plus $2 per part for dissecting material. Board can be had at the school dining hall for $9 a month, and a room in the dormitory for $15 a term. The Dean is Dr. Robert Reyburn, 714 13th St. N. W., Washington. Total registration for the year 1901-2 was 145; graduates, 27. The thirty-fifth session begins Oct. 1, 1902, and closes May, 1903.

National University Medical Department.—This school, organized in 1884, is a member of the Association of American Medical Colleges, and has a faculty of 37. Clinical facilities are obtained at the Providence, Garfield and Episcopal hospitals, the Eastern and Presbyterian dispensaries and the Home for Incurables. Instruction is given by lectures, recitations, clinical teaching and practical laboratory work. Oral examinations are held each week and final examinations, *both oral and written, at the* end of each lecture term. The course consists of graded work for four years of eight months each. The total fees for each year are $100, except the first, when an additional fee of $5 is charged. The Dean is Dr. H. H. Barker, 1116 H St. N. W. Total registration for 1901-2 was 37; graduates, 9. The nineteenth session will begin Oct. 6, 1902, and will extend to May 31, 1903.

GEORGIA.

Georgia, population 2,216,331, has three medical colleges: Medical College of Georgia, located in Augusta (population, 39,441); Atlanta College of Physicians and Surgeons and Georgia College of Eclectic Medicine and Surgery, both in *Atlanta (a manufacturing* city of 89,872 population).

Augusta.

Medical College of Georgia.—This school was organized as a medical academy in 1829, and in 1873 *was made the Medical Department* of the University of Georgia. Its faculty includes 15 professors and 5 assistants, 20 in all. All students who entered on their first course after Sept. 30, 1900, must attend four sessions of six months each. Applicants for admission must, by examination, certificate or diploma, show that they possess an education equal to that required for second grade teachers in public schools; if they are deficient on examination, however, they are admitted *and they may remove the* condition any time before they appear for graduation. The City Hospital, with 130 beds; Lamar Hospital, with 80; the Polyclinic and the Hospital for Contagious Diseases supply clinical material. Total fees for first two years are $100 each; third year, $90, and $120 for the last year. Board and lodging can be procured for from $3 to $5 a week. The Dean is Dr. Eugene Foster, Augusta. Total enrolment for 1901-2 was 121; graduates., 47. The seventy-first session opens Oct. 1, 1902, and closes April, 1903.

Atlanta.

Atlanta College of Physicians and Surgeons.—This school was formed in 1898 by the consolidation of the Atlanta Medical College, organized in 1854, with the Southern Medical College, organized in 1879. It has a faculty of 14 professors and an adjunct faculty of 14, a total of 28. Clinical facilities are furnished by the Grady Hospital, which is the general hospital for Atlanta; clinics are free to the graduating class. First course students are required to "give satisfactory evidence to the faculty of such educational qualifications as will be deemed necessary for the successful prosecution of their medical studies. These requirements will be similar to those of other reputable medical colleges in the country." *The course of* study covers four years of six months each and is graded. The buildings are large and a new building for practical anatomy has just been added. Fees: First and second years, $75 each; third and fourth, $100 each. Board and room can be obtained for from $3 to $4 per week. The Dean is Dr. W. S. Kendrick, 71 Washington St., Atlanta. Total registration of students for 1901-2 was 257; graduates, 111. Next session begins Oct. 1, 1902, and closes April 4, 1903.

Georgia College of Eclectic Medicine and Surgery.—This was organized in 1886, and has a faculty of 11 professors and 1 demonstrator. The college dispensary and Grady Hospital furnish clinical material. Applicants for admission must adhere to the requirements established by the National Confederation of Eclectic Colleges, of which this college is a member. The curriculum covers four years of six months each. The Proctor is W. M. Durham, M.D., 77½ Peachtree St., Atlanta. Total number of students for 1901-2 was 58; graduates, 21. The next session opens Oct. 1, 1902, and closes April 1, 1903.

ILLINOIS.

Illinois, population 4,821,550, has fifteen medical colleges. They are all located in Chicago, a city with 1,698,575 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, Hahnemann Medical College, Bennett College of Eclectic Medicine and Surgery, Chicago Homeopathic Medical College, College of Physicians and Surgeons, Hering Medical College, Jenner Medical College, Harvey Medical College, Illinois Medical College, Dunham Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University and Chicago Eclectic College. Room and board can be obtained for from $2.50 a week upwards.

Chicago.

Rush Medical College.—This school was founded in 1837, organized in 1843, was the Medical Department of Lake Forest University from 1887 to 1898, and in the latter year became affiliated with the University of Chicago. The faculty is composed of 26 professors, 31 associate and assistant professors, and 137 instructors, assistants, etc., a total of 194. Good clinical facilities are furnished by Cook County Hospital, caring for about 20,000 patients yearly; Presbyterian Hospital, with 250 beds; a college dispensary, and an obstetric department. In addition to these, extramural clinical courses are offered at the West Side Hebrew Dispensary, St. Luke's Hospital, St. Anthony's Hospital, The Alexian Brothers' Hospital, Illinois Charitable Eye and Ear Infirmary and Chicago Isolation Hospital. Bedside instruction is given. The requirements for admission are those of admission to the better universities or colleges and, in addition thereto, one year of college work. For the sessions of 1903 there will be required a certificate of admission to the second academic year of an accredited university, and for 1904-5 to the third year. By the addition of a recently completed seven-story building, the facilities for clinical instructions are largely increased. The laboratories and their equipment are unexcelled. The curriculum covers graded work for four years of three quarters each, a quarter being *three months*. A continuous session is held, but credit for more than three quarters can not be obtained in any calendar year. A combined course for six years confers degrees of both science and medicine. All freshmen and sophomore studies are given at the University of Chicago. The total regular fees are $165 this year, but it is designed to *gradually increase the* fees to $200 per year. However, students in *continuous attendance*, i. e., three quarters in twelve months, may complete their course by paying the fees in vogue when they first enter the college. A matriculation fee of $5 is paid but once, and there are incidentals amounting to from $2 to $5 annually. The Deans are Dr. Frank Billings, 100 State St., and Dr. John M. Dodson, 34 Washington St., Chicago. Total registration 1901-2 was 803; graduates, 211. The fiscal year begins July 1; final examinations are held at the end of each quarter for those who have completed their work.

Northwestern University Medical School.—This school was organized in 1859 as the Medical Department of Lind University, became independent as the Chicago Medical College in 1864, and in 1869 assumed its present relation as Medical Department of Northwestern University. The faculty comprises 33 professors, 6 associates and assistants, and 54 instructors, demonstrators, etc., in all, 93. The newly completed Wesley Hospital, with 225 beds; Mercy Hospital, containing 400 beds; Provident Hospital, having 100 beds, and a college free dispensary furnish opportunities for clinical study to students of this college exclusively. St. Luke's, *Cook County, and the Chicago Lying-in* hospitals are also open to them for study. Applicants for admission must, by diploma, certificate or examination, show possession of the educational acquirements required to enter the College of Liberal Arts of Northwestern University. This school is a member of the Association of *American Medical Colleges. The laboratory* and lecture-room facilities are ample and the equipment is good. The course of study covers graded work for four years of thirty-six weeks each. Final examinations are held at the end of each semester. The fees for each year are $135 and a matriculation fee of $5, paid once, is charged. *The Dean is Dr. N. S. Davis, Jr.*, 65 Randolph St., Chicago. The total registration for 1901-2 was 465; graduates, 96 The next session opens Oct. 7, 1902, and closes June 18, 1903.

Hahnemann Medical College.—Homeopathic. This was organized in 1851, and has a faculty of 52. Hahnemann Hospital and *a college dispensary supply clinical* material. The requirements for admission are sufficient knowledge of English, arithmetic, geography, algebra, physics, United States history and Latin. The course is four years of seven months each. Fees: Matriculation, paid once, $5; each term, $50, and hospital tickets, $5 each for *third and fourth years*. The Dean is Dr. E. Stillman Bailey, Marshall Field Bldg. Total registration, 1901-2, was 185; graduates, 47. The next session begins Oct. 1, 1902, and ends May 7, 1903.

Bennett College of Eclectic Medicine and Surgery.—This school, organized in 1868, has a faculty of 26 professors and 13 assistants, 39 in *all*. The Bennett, Cook County and Baptist hospitals and a college dispensary supply clinical facilities. Matriculants must present a diploma or certificate or pass a satisfactory examination "in conformity with the minimum requirements of the State Board of Health." The course covers four *years of twenty-six* weeks each. This school is *a member of the* National Confederation of Eclectic Medical Colleges. Fees for each year are $100, with a matriculation fee, paid once, of $5. The Dean is Dr. A. L. Clark, Elgin, Ill. Total registration, 1901-2, was 104; graduates, 21. The thirty-fifth session begins Sept. 23, 1902, *and ends May* 13, 1903.

Chicago Homeopathic Medical College.—This was organized in 1876, and has a faculty of 19 professors and 49 adjuncts, lecturers, etc., a total of 68. The Chicago Homeopathic and Cook County hospitals, together with a college dispensary, furnish clinical *material.* Applicants for admission must show by certificate from high school, or its equivalent, a sufficient knowledge of English, arithmetic, algebra, physics, United States history, geography, botany, and Latin equivalent to a year's study. The course covers four years of seven and one-half months each. Total fees are about $110 for each year. The Dean is Dr. W. M. Stearns, Marshall Field Bldg. Total registration, 1901-2, was 130; graduates, 35. The next session opens Sept. 16, 1902, and ends April 28, 1903.

College of Physicians and Surgeons.—This school was organized in 1882 and in 1896 became the Medical Department of the University of Illinois. *The faculty* is composed *of 39 professors*, 38 adjuncts and clinical professors and 38 instructors, etc., a total of 115. The West Side Hospital, containing 125 beds; Cook County Hospital, and a college dispensary and maternity clinic supply most of the clinical material, but under certain conditions students of this school are admitted to the following hospitals for clinical study: Augustana Baptist, Chicago, Woman's, Samaritan, Alexian Brothers', St. Mary's, and the Chicago Lying-in. This school is a member of the Association of American Medical Colleges. A magnificent building has recently been added to the college, and the laboratory, amphitheater and lecture-room space and equipment are excellent. The collegiate year is divided into two terms: the winter term of thirty-two weeks and the summer term of twelve weeks, of actual teaching. Attendance on the winter term is required in order to secure credit for a year's work, and attendance on four winter terms is required for graduation, except for students who are admitted to advanced standing. Attendance on the summer term is optional, and the work is supplementary to the work of the winter term. Students may obtain credit for work done in certain branches, but attendance on this term does not apply on the required thirty-two months' attendance necessary for graduation. The fees are $130 each for the first two years, $115 for the third and $125 for the fourth year. The Dean is Dr. William E. Quine, 103 State St. Total registration for 1901-2 was 692; graduates, 220. The fall term begins Oct. 1, 1902.

Hering Medical College.—Homeopathic. This school was organized in 1892. The faculty comprises 25 professors and 14 associates, lecturers, etc., in all 39. Hering College Hospital, National Temperance and Cook County hospitals supply clinical facilities. The course covers four years of seven months each. The total fees for a full course are $300 if paid in advance, or $100 per year. The Dean is Dr. H. C. Allen, 5142 Washington Ave. Total registration for 1901-2, was 72; graduates, 13. The eleventh session begins Sept. 9, 1902, and ends April 11, 1903.

Jenner Medical College —This is a day and evening school organized in 1892 The faculty consists of 28 professors and 7 assistants 35 in all Cook County Hospital and college dispensary supply clinical material, and the new Union Stock Yards Hospital will soon add to the facilities for clinical work This college belongs to the Association of American Medical Colleges The course covers four years of 44 weeks each and embraces laboratory didactic and clinical instruction The total fees each year are $100 with a $5 matriculation fee paid but once The Secretary is Dr A Loewy 196 Washington St Total enrolment for 1901 2 was 105, graduates 18 The present session began Sept 2 1902, and will end June 30 1903

Harvey Medical College —This is a night school, organized in the Chicago Atheneum in 1891 and reorganized in 1894 The lecture and laboratory work is all in the evening between the hours of 7 and 10, six days of the week and forty weeks of the year The clinical work hospital, dispensary, in practice and out practice are between the hours of 10 a m and 10 p m Attendance on 100 clinical hours yearly before 7 in the evening is obligatory besides attendance by the seniors on night obstetric cases and Saturday evening clinic at Cook County Hospital The faculty is composed of 42 professors 21 instructors and assistants, total, 63 The course covers four years of ten months each The requirements for admission are those of the Association of American Medical Colleges The total fees for first three years are about $125 each, and for the fourth year $150 The Dean is Dr Francis Dickinson Total registration for 1901 2 was 307 graduates 28 The twelfth session began Sept 2, 1902 and ends June 27, 1903

Illinois Medical College —This school organized in 1894, has a faculty of 24 professors and 19 assistants a total of 43 A college dispensary and Cook County Hospital are available for clinical study The requirements for admission are based on those of the Association of American Medical Colleges and include a high school diploma or its equivalent The college is a member of the Association of American Medical Colleges A continuous course consisting of four terms to the calendar year is offered, two terms of three months each constituting a college year Four collegiate years are necessary for graduation and forty two months must elapse between that time and matriculation Total fees are about $75 for each year The Dean is Dr B B Eads 103 State St Total registration for 1901 2 was 228 graduates 21 The next fall term begins Oct 1 1902

Dunham Medical College —Homeopathic This was organized in 1895 and has a faculty of 31 professors and lecturers Cook County Hospital St Anthony s Hospital and a college dispensary supply the clinical facilities Four years' work of seven months each is required for graduation The fees are about $100 for each year The Dean is Dr James E Kent, 92 State St Total registration for 1901 2 was 82 graduates 19 The twelfth session begins Sept 23 1902 and ends April 28, 1903

American Medical Missionary College —This school was organized in 1895 and has the primal object of educating men and women as missionary physicians The faculty numbers 25 The didactics and laboratory work covering the first two years is carried on at Battle Creek Mich and the clinical studies in Chicago A hospital with 20 beds in connection with the college, together with a free college dispensary, with an obstetric department, supply material for practical work The requirements are based on those of the Association of American Medical Colleges The course covers four years of nine months each Total fees are $125 for each of the four years The Secretary is Dr E L Eggleston, Battle Creek Mich Total registration for 1901 2 was 92; graduates 24 The eighth session opens Sept 24, 1902, and closes June 23 1903

College of Medicine and Surgery —Physio Medical This school was organized in 1896 and has a faculty of 31 teachers A college dispensary supplies material for clinical work The course covers four years of seven months each Fees for the first year $100, for the second and third, $95 each, and $110 for the fourth The Dean is Dr H P Nelson 631 Jackson Blvd Total registration for 1901 2 was 40 graduates 9 The next session begins Sept 26 1902 and ends April 27, 1903

National Medical University —This was organized in 1891, and its courses include instruction in the methods of all the so called schools of practice The faculty numbers 54 The requirements for entrance are a high school diploma or examination in accordance with the requirements of the Illinois State Board of Health A 4 year course of 6 months each has been required, but 9 months are now necessary in each year, and after 1902, 5 years of 9 months each will be necessary for graduation the fifth year being spent in the hospital Each year is divided into 4 quarters of 13 weeks each The fees are $100 per year or $300 for the four if paid in advance The Registrar is Dr L D Rogers, 533 Wells St Total matriculants for 1901 2 were 150, graduates, 11 The autumn quarter will begin October 1

American College of Medicine and Surgery —Eclectic This school was founded in 1901 and has now purchased the buildings of the Northwestern University Woman's Medical School which passed out of being this year It has a faculty of 50 The requirements for entrance are in accord with the rules of the State Board of Health The course is four years of eight months each American and Cook County hospitals supply clinical material The Secretary is Dr J D Robertson 103 State St The enrolment 1901 2 was 36 The next session begins Oct 1, 1902, and closes May 15, 1903

INDIANA

Indiana, population 2,516,462, has five medical colleges Four are situated in Indianapolis, a city of 169,164 people. The Physio Medical College, Central Medical College of Indiana, Central College of Physicians and Surgeons, and the Eclectic Medical College The clinical facilities of Indianapolis are good and board and lodging can be obtained from $2 50 a week upwards The Fort Wayne College of Medicine is situated in Fort Wayne, a railroad and manufacturing town of 45,115 inhabitants Board and room can be obtained there at an average of $3 a week

Indianapolis.

Physio Medical College —This school was organized in 1873, and has a faculty of 29 The course is four years of 26 weeks each Total fees for each year are $70 The Secretary is Dr C T Bedford, Indianapolis Total enrolment 1901 2, was 31, graduates 4 The next session begins Oct 7, 1902, and closes April 7, 1903

Medical College of Indiana —This is the Medical Department of the University of Indianapolis and was organized in 1869 The faculty embraces 25 professors and 39 adjuncts lecturers etc, total of 64 The City Hospital containing 200 beds, Indianapolis Dispensary, Central Hospital for the Insane with a capacity for 1800 patients, St Vincent s and the Maternity hospitals and a college dispensary provide clinical facilities the wards in the charity hospitals are open to students of this college for bedside instruction The laboratory and lecture room space is ample This college is a member of the Association of American Medica Colleges The course extends over four years of seven months each Fees first and second years, $80 each, third, $75, and $100 for the fourth year, which includes
is Dr Henry Jameson, Newton Claypool
enrolment for 1901 2 was 311, gradua
session opens Sept 23, 1902 and closes April 23, 1903

Central College of Physicians and Surgeons —This school was organized in 1879 and reorganized in 1901, at which time its faculty was greatly enlarged now numbering 23 professors, 50 lecturers and demonstrators total 73 A new college building has been erected on the most up to-date plans Its floor space comprises 25 000 square feet more than half of which is devoted to laboratory teaching The school gives instruction largely by laboratory and clinical methods Clinical facilities are furnished by a dispensary maintained by the college by the City Dispensary, City Hospital, St Vincent's Infirmary and the Central Hospital for the Insane This college was a charter member of the Association of American Medical Colleges The course is four years of 6 months each The Dean is Dr Allison Maxwell The fees are $75 for each year of the four years' course The session for 1902 3 will open Oct 2, 1902 Total registration 1901 2 was 70, graduates, 8

Eclectic Medical College —This school was organized in 1889 It has a teaching force of 31 The requirements for admission are those of the National Confederation of Eclectic Medical Colleges The catalogue shows a four year course of six months each Fees For each year, $75 or for all four $225, $25 for graduation Total registration, 1901 2, 25 The next session begins Sept 23, 1902, and ends April 11, 1903 The Dean is Dr R T Laycock, 909 Bates St

Fort Wayne.

Fort Wayne College of Medicine —This school was organized in 1879, has a faculty of 25 professors and 8 lecturers and assistants a total of 33 St Joseph s Hospital with a capacity of 250 patients, Hope Hospital, with 200 beds St Roche s Hospital having accommodation for 35 patients Indiana School for Feeble-Minded Youth and Allen County Orphan Asylum, capable of holding 150 children, supply the clinical facilities This school is a member of the Association of American Medical Colleges The curriculum covers four years of seven months each The course is practical, supplemented by lectures and laboratory work The total fees for each year are $75, with an additional $5 matriculation fee payable once The Dean is Dr C B Stemen 25 Broadway Total number of students registered 1901 2 was 46, graduates 9 The present session opens September 10, 1902 and closes April 21, 1903

IOWA.

Iowa, population 2,231,853, contains five medical colleges They are College of Medicine of the State University of Iowa, College of Homeopathic Medicine of the State University of Iowa, Iowa College of Physicians and Surgeons, Sioux City College of Medicine, and Keokuk Medical College, College of Physicians and Surgeons

Iowa City.

College of Medicine of the State University of Iowa —This is situated in Iowa City, population 7987, and was organized as the Medical Department of the State University in 1870 The faculty is made up of 14 professors 7 lecturers and 17 demonstrators and assistants, a total of 38 The University Hospital, built in 1897 at a cost of $50 000, supplies abundant clinical material The school is a member of the Association of American Medical Colleges The course of study covers four years of thirty six weeks each, embracing graded laboratory, didactic and clinical work Combined courses leading to more than one degree are offered Total fees for each year are $65 Board and lodging costs from $2 50 to $5 per week The Dean is Dr James R Guthrie Dubuque Total number of students registered for 1901 2 was 248, graduates, 40 The thirty third course of lectures opens Sept 24 1902, and will end June 17 1903

College of Homeopathic Medicine of the State University of Iowa —This was organized in 1877 The faculty is composed of 10 professors, and 9 lecturers and assistants, a total of 19, but some of these are of the faculty of the College of Medicine The requirements for admission and the work, with the exception of that pertaining to homeopathy, are the same as those for the other department The fees are also the same The Dean is Dr George Royal, Des Moines Total registration for 1901 2 was 59, graduates, 7 The twenty sixth session begins in September, 1902, and will end in June, 1903

Des Moines.

The Iowa College of Physicians and Surgeons —This is the Medical Department of Drake University and is located in Des Moines population 62 139 It was organized in 1882 The faculty contains 17 professors and 6 assistants, a total of 23. Mercy and Methodist hospitals furnish clinical material and attendance on clinics is required the same as on lectures. The requirements for admission are those determined by the Association of American Medical Colleges and the Iowa State Board of Medical Examiners. Instruction is given by means of lectures, recitations, demonstrations, laboratory work and hospital clinics. The work covers a graded course of four years of nine months each. Board and lodging can be obtained for $15 a month. The total fees for the first two years are $80 each, and for the last two years, $75 each. The Dean is Dr. Lewis Schooler, Des Moines. The total registration for the year 1901-2 was 64; graduates, 10. The twenty-first session began Sept. 5, 1902, and will end June 13, 1903.

Sioux City.

Sioux City College of Medicine.—This is located in Sioux City, population 33,111, and was organized in 1891. The faculty numbers 15. Clinical material is supplied by St. Joseph's, Mercy and Samaritan hospitals and a college dispensary. This college is a member of the Association of American Medical Colleges. The system of study embraces a four-year graded course, eight months being a school year. Final examinations are held at the close of each course of instruction. Matriculation fee, paid but once, $5; tuition, each year, $48; hospital fee, $5, and graduating fee, $20. The Dean is Dr. H. A. Wheeler. Total number of students registered, 1901-2, was 63; graduates, 10. The thirteenth session opens Sept. 10, 1902, and will close April 20, 1903.

Keokuk.

Keokuk Medical College, College of Physicians and Surgeons.—In 1849 the College of Physicians and Surgeons, Keokuk, was organized and four years later it became the Medical Department of the Universitv of Iowa, continuing as such until 1870, when the original name was resumed. By the union, in 1899, of this college with the Keokuk Medical College, organized in 1890, the present school under the above name was founded. Situated in Keokuk, a town of 14,641 people, and drawing much from the surrounding country, the clinical material is good. St. Joseph's Hospital is open to the student for study and the clinics held there are large and varied. The faculty is composed of 17 professors and 1 demonstrator, 18 in all. This college is a member of the Association of American Medical Colleges. The studies embrace a graded course of four years of seven months each. Board and room can be secured for from $2 to $4 per week. The total fees for the first year are $63; for the second and third, $58 each, and $53 for the last year. The Secretary is Dr. Oliver D. Walker, Keokuk. Total registration for 1901-2 was 247; graduates, 52. The next session begins Sept. 23, 1902, and ends April 28, 1903.

KANSAS.

Kansas, population 1,470,495, has two medical colleges, as follows: Kansas Medical College in Topeka (population 33,608), and the College of Physicians and Surgeons, situated in Kansas City (population 55,000).

Topeka.

Kansas Medical College.—This college, organized in 1890, has a faculty of 27 professors and 6 lecturers and assistants, 33 in all. Good material for both medical and surgical clinics is found in Christ's Hospital, with 100 beds, and Topeka State Hospital; the dispensary, in the down town district, also supplies material for class demonstration. The college is a member of the Association of American Medical Colleges. The college building affords ample laboratory and lecture-room space. The course of study is a graded one covering four years of twenty-six weeks each. Individual instruction is especially aimed at. The total fees for the first two years are $70 each, and $65 each for the last two years. The cost of board and room varies from $2.50 to $4 a week. The Dean is Dr. John E. Minney, Topeka. The total registration for 1901-2 was 99. The thirteenth session begins Sept. 16, 1902, and will close March 27, 1903.

Kansas City.

College of Physicians and Surgeons.—This was organized in 1894 as the Medical Department of Kansas City University. The faculty is made up of 29 professors, 3 lecturers and 5 demonstrators and assistants, a total of 37. Bethany Hospital, with 60 beds; St. Margaret's Hospital, a college dispensary, and an outside obstetric department supply clinical material. Practical demonstration and bedside teaching is emphasized in the work. The requirements for admission are in accordance with the rules of the Association of American Medical Colleges. The course of study is a graded one of four years, seven months each. A scholarship is offered for $175, but taken separately the total fees for the first three years are $60 each, and for the fourth year $50; matriculation fee, $5, payable but once. The Dean is Dr. J. W. May. The total registration of students for 1901-2 was 73; graduates, 27. The ninth session opened Sept. 2, 1902, and will close March 25, 1903.

KENTUCKY.

Kentucky, population 2,147,174, has eight medical colleges. They are all situated in Louisville, a growing city of 204,731 inhabitants, and are as follows: : University of Louisville Medical Department, Kentucky School of Medicine and Hospital, Louisville Medical College, Hospital College of Medicine, Southwestern Homeopathic Medical College, Kentucky University Medical Department, Louisville National Medical College, and Medical Department of State University. Board and lodging can be obtained in Louisville from $2.50 to $4 per week.

Louisville.

University of Louisville Medical Department.—This school was organized in 1837, under the name, Louisville Medical Institute, and in 1846 assumed its present title. It has a faculty of 11 professors, 26 lecturers, demonstrators, etc., a total of 37. The University Hospital, City Hospital, St. Mary's and St. Elizabeth's hospitals, together with the college dispensary, furnish good clinical material. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of six months each. Total fees: First year, $107; second, $122; third, $105, and fourth, $117. The Dean is Dr. J. M. Bodine, Louisville. Total registration for 1901-2 was 180; graduates, 31. The sixty-sixth session begins Sept. 29, 1902, and ends July 1, 1903.

Kentucky School of Medicine.—This school was organized in 1850, and has a faculty composed of 12 professors, 10 lecturers and 16 instructors and assistants, a total of 38. The College Hospital, City Hospital and the college dispensary furnish the facilities for clinical study. The student is brought directly into contact with the patient through dispensary and bedside work by dividing the classes into sections. This college is a member of the Association of American Medical Colleges. The laboratories and their equipment are good. The curriculum embraces a four years' course of six and a half months each. The fees for the first two years are $110 each; for the third year, $90, and $80 for the fourth year. The Dean is Dr. W. H. Wathen, 658 Fourth Ave. Total number of students registered for 1901-2 was 295; graduates, 45. The next session begins Jan. 2, 1903, and will end July 1, 1903.

Louisville Medical College.—This school was organized in 1869 and has a faculry of 10 professors and 13 instructors and assistants, 23 in all. The City Hospital, College Infirmary and a dispensary offer good clinical facilities. Applicants for admission must show by diploma, certificate or examination that they are sufficiently proficient in English, arithmetic, algebra, physics and such Latin as would be acquired in one year's study. The laboratories and lecture rooms are ample. The course of study covers four years of six months each. The total fees for each year are $100. The Dean is Dr. C. W. Kelly. Total registration of students for 1901-2 was 219; graduates, 29. The next session opens Sept. 15, 1902, and closes March, 1903.

Hospital College of Medicine.—This school is the medical department of Central University of Kentucky and was organized in 1873. The faculty is composed of 9 professors, 9 adjuncts and 23 lecturers, demonstrators, etc., a total of 41. The Gray Street Infirmary, City Hospital and a well-equipped college dispensary present good facilities for clinical study. The requirements for admission are those of the Association of American Medical Colleges. Laboratory work, which is a prominent feature of the course, is thorough and practical. The laboratories and amphitheaters are ample in equipment and capacity, and the hospital advantages give opportunity for personal bedside instruction. The course covers four years of six months each. Total fees for each of first two years, $120; for the third year, $85, and $125 for the fourth year. The Dean is Dr. P. Richard Taylor. Total enrolment for 1901-2 was 407; graduates, 65. The twenty-ninth session opens Jan. 1, 1903, and closes July 1, 1903.

Southwestern Homeopathic Medical College.—This college was organized in 1892 and has a faculty of 18 professors and 13 lecturers and assistants, 31 in all. A college dispensary supplies clinical material. The curriculum covers four years of seven months each. Total fees: First and second years, $85; third, $75, and $70 for the fourth. The Dean is Dr. A. L. Monroe. Total number of students for 1901-2 was 27: graduates, 4. Next session opens Sept. 30, 1902, and closes April 28, 1903.

Kentucky University Medical Department.—This school was organized in 1898. The faculty is composed of 14 professors, 19 lecturers, demonstrators, etc., 33 in all. Broadway Infirmary, the City Hospital, and a college dispensary furnish clinical material. The school is a member of the Association of American Medical Colleges. The buildings provide ample facilities for clinical, laboratory and didactic instruction. The course of study embraces graded work for four years of at least twenty-six weeks each. Total fees: First year, $110; second, $120; third, $90; and $120 for the fourth year. The Dean is Dr. Thomas C. Evans, 419 W. Chestnut St. Total number of students registered in 1901-2 was 238; graduates, 18. The next session opens Jan. 2, 1903, and closes July 2, 1903.

Medical Department of State University.—This is a school for colored students organized in 1899. The faculty numbers 12. Instruction is given at night. The course is four years, of six months each. Total matriculants for 1901-2 were 16. The Dean is Dr. W. T. Merchant.

Louisville National Medical College.—Colored. This was chartered in 1888 and shows a teaching force of 15. There is a four-year course, seven months to the year: the total fees are about $50 for each year. The Dean is Dr. W. A. Burney. The next session opens Oct. 14, 1902. Graduates, 1902, numbered 7.

LOUISIANA.

Louisiana, having a population of 1,381,625, contains two medical colleges: Medical Department of the Tulane University of Louisiana and New Orleans University. They are both situated in New Orleans, a city of 287,104 people. The cost of room and board is from $10 to $22 a month.

New Orleans.

Medical Department of the Tulane University of Louisiana. This school was organized in 1834 as the Medical College of Louisiana, and became by law in 1847 the Medical Department of the University of Louisiana, and in 1884 the Medical Department of the Tulane University of Louisiana. The faculty and all other instructors number 40. By acts of legislature the Charity Hospital, with its 900 beds, has been opened to the students of this school for clinical study not only in medicine and surgery, but also in obstetrics and gynecology. In the year 1901 there were 8368 cases treated in the wards of this hospital; these were indoor patients, and, in addition, 21,164 outdoor patients were treated in the free dispensary department. The Milliken Memorial Hospital, with a capacity for 200 children, is also available for study of clinical cases. Bedside instruction is given by the attending physicians to these hospitals, and postmortem examinations are held before the students. The requirements for admission to this college are those of the Southern Medical College Association. The laboratories are large and well equipped, and the lecture and recitation rooms are ample. The course of study covers four years of six months each. Total fees for the first two years are $135 each, and for the third and fourth, $145 and $165, respectively. The Dean is Dr. Stanford E. Chaille, New Orleans. The total number of students registered for 1901-2 was 361; graduates, 53. The sixty-seventh session begins Oct. 23, 1902, and will close April 29, 1903.

Flint Medical College of New Orleans University.—Colored. This school was organized in 1889. The faculty is made up of 8 professors, 3 lecturers and 3 instructors, 14 in all. Clinical material is supplied by the Sarah Goodridge Hospital and by an outdoor clinic. This college is a member of the Association of American Medical Colleges. The curriculum covers a graded course of four years, twenty-six weeks each. T[illegible]ecture rooms are ample. Examinations are hel[illegible]s for the first year are $34; for the second, [illegible] and $40 for the last year. The Dean is [illegible] New Orleans. Total enrolment for 1901-2 was 47; graduates, 4. The thirteenth college year began Sept. 3, 1902, and will end March 6, 1903.

MAINE.

Maine, population 694,466, has one medical college:

Portland.

Medical School of Maine.—This is the Medical Department of Bowdoin College. It was organized in 1820. It has 13 professors and 5 instructors, total 18. Students of the first and second years are instructed in Brunswick, a town with 6800 inhabitants. The third and fourth year classes are taught in Portland, a city of 50,000 inhabitants and where are situated the Maine General Hospital and other clinical advantages. Applicants for admission, unless they possess a diploma, are examined in English, arithmetic, algebra, geometry, United States history, physics, chemistry and Latin. The course covers four years of twenty-six weeks each. The total fees are $120 for the first year; for the second and third, $110, and $130 for the fourth year. Board and lodging cost from $3 to $5 a week. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1902, 90; graduates 4, under the former three-year requirement; no fourth-year graduates until 1903. The next session opens Dec. 25, 1902, and closes June 25, 1903.

MARYLAND.

Maryland, with a population of 1,188,044, contains eight medical colleges. They are all located in Baltimore, a city with 508,957 inhabitants, and they are as follows: School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore University School of Medicine, Baltimore Medical College, Woman's Medical College, Southern Homeopathic Medical College, Johns Hopkins Medical School and Maryland Medical College. The Bay View Hospital, having a capacity for 2000 patients, is open to students for clinical instruction, and furnishes good opportunities for practical demonstrations. Board and lodging can be obtained for from $3 to $5 per week.

Baltimore.

School of Medicine of the University of Maryland.—This institution was organized in 1807 as the College of Medicine of Maryland, and in 1812, other faculties having been added, the whole was chartered under the name of the University of Maryland. The faculty is composed of 14 professors, 21 clinical and associate professors, and 24 lecturers, demonstrators, etc., a total of 59. The University Hospital, a part of which is used for a hospital for foreign seamen and another portion for a free city hospital, offers excellent clinical facilities. Besides this, the Presbyterian Eye, Ear and Throat Charity Hospital, in which 10,734 patients were treated in 1900; the Hospital for the Relief of Crippled and Deformed Children, containing 40 beds; the Maternity Hospital, and a college dispensary furnish material for clinical study. This school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are ample and well equipped. The fourth-year class, divided into sections, receives special training in practical laboratory work in a well-appointed clinical laboratory. Didactic, laboratory and clinical instructions, special attention being paid to bedside work, make up the system of teaching. The course covers four years of seven months each, and is graded. The total fees for the first two years are $120 each; for the third year, $110, and $140 for the final year. The Dean is Dr. R. Dorsey Coale, Baltimore. The total number of students registered in 1901-2 was 366; graduates, 76. The ninety-sixth session begins Oct. 1, 1902, and will terminate May 15, 1903.

College of Physicians and Surgeons, Baltimore.—This school was organized in 1872, and in 1878 Washington University School of Medicine, established in 1827, was consolidated with it. The faculty numbers 50. The clinical facilities, besides those afforded in common with other schools, are supplied by the Baltimore City Hospital, the Hospital for the Colored Race, containing 100 beds; the Nursery and Child's Hospital, with 150 beds; the Maryland Lying-in Asylum, and a college dispensary. This school is a member of the Association of American Medical Colleges. The work covers a graded course of four years, seven months constituting a year. Total fees for the first three years are $115 each, and $135 for the last year. The Dean is Dr. Thomas Opie. The total number of students registered in 1901-2 was 305; graduates, 58. The next session opens Sept. 30, 1902, and closes April 16, 1903.

Baltimore Medical College.—This college was organized in 1881, and has a faculty of 52. The clinical material is furnished by the Maryland General Hospital, having a capacity of 200 beds; the Maryland Lying-in Hospital, the Mount Hope Retreat, which presents good opportunity for the study of nervous and mental diseases, and a college dispensary, which, besides the great number of ambulatory patients treated, has an outdoor department that permits of the advanced student taking care of charity cases and carrying out his own treatment. This college belongs to the Association of American Medical Colleges. The college buildings afford ample laboratory, clinical and lecture-room space. Bedside teaching in the hospital wards is carried on in sections and every member of the senior class is required to attend throughout the session. The course of study is graded and covers four years of seven months each. The Dean is Dr. David Streett. The total number of students registered in 1901-2 was 532; graduates, 93. The twenty-second session opens Sept. 25, 1902, and closes about April 27, 1903.

Woman's Medical College.—This school was organized in 1882 and has a faculty of 14 professors, 4 adjunct professors, and 9 assistants and lecturers, a total of 27. The Hospital of the Woman's Medical College, St. Mary's Asylum and a college dispensary furnish clinical material. The college is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are equipped with all necessary apparatus; the practical work is emphasized. Eight months constitute a school year, and the course covers graded work for four years. The total fees for the first three years are $105 each, and $85 for the last year. Total number registered for 1901-2 was 25; graduates, 4. The twenty-first session opens Oct. 1, 1902, and closes May 29, 1903.

Baltimore University School of Medicine.—This school, organized in 1884, has a faculty of 12 professors and 11 lecturers, demonstrators, etc., in all 28. The Baltimore University Hospital, Lying-in Hospital and the clinical material used in common with the other schools, supply the facilities for practical work. This college is a member of the Association of American Medical Colleges. The college dispensary affords much clinical material and the students, under the direction of the physician in charge, make calls and treat patients at their homes. The lecture rooms and laboratories are ample, and the course of instruction, which consists of graded work for four years of six months each, is practical. The total fees for the first two years are $100 each; for the third year, $80, and $110 for the fourth year. The Dean is Dr. Hampson H. Biedler, 119 W. Saratoga St. Total registration for year 1901-2 was 63; graduates, 31. The nineteenth session opens Oct. 1, 1902, and closes April 15, 1903.

Southern Homeopathic Medical College.—This school was organized in 1890, and has a faculty of 11 professors, 4 associate professors, and 19 lecturers and demonstrators, a total of 34. The clinical facilities are those offered by the Maryland Homeopathic Hospital, which has 55 beds, and the dispensary; the obstetric department also furnishes clinical material. Applicants for matriculation must pass a satisfactory examination in English, arithmetic, geography, history, and Latin, unless they possess satisfactory evidence that they have done a corresponding amount of work. The course covers graded work for four years, seven months to the year. The fees are $105 for the first year, $100 each for the second and third, and $130 for the last year; $350 in advance for the full four years' course. The Dean is Dr. George T. Shower, 421 Roland Ave. Total registration 1901-2 was 35; graduates, 9. The twelfth session begins Oct. 6, 1902, and ends May 2, 1903.

Johns Hopkins Medical School.—This is the Medical Department of Johns Hopkins University and was organized in 1893. The faculty comprises 11 professors, 17 clinical and associate professors, 16 lecturers and associates, and 25 instructors and assistants, a total of 69. The Johns Hopkins Hospital and Dispensary furnishes abundant and varied clinical material; the lying-in department of the hospital, opened in 1896, is in successful operation. The requirements for admission demand that the applicant either has, (a) completed the chemical-biologic course which leads to the A.B. degree in the University; (b) graduated at an approved college or scientific school, and can furnish evidence of an acquaintance with Latin and a fair reading knowledge of French and German, and such knowledge of physics, chemistry and biology as above indicated. If the candidate is unable to show this, he must pass a satisfactory examination covering this ground. This school is a member of the Association of American Medical Colleges. The anatomic, physiologic, pharmacologic, pathologic and clinical laboratories are large, well lighted and well equipped. The buildings are ample and built expressly for the purpose for which they are used. In the method of instruction special emphasis is laid upon practical work in the laboratories, dispensary and in the wards of the hospital. The first two years are devoted to practical work in the laboratories, combined with demonstrations, recitations and lectures, and during the remainder of the course opportunity for the personal study of cases is given. The work covers a graded course of four years and eight and a half months to the year. Final examinations, partly written and partly oral, include practical tests in laboratory and clinical work; the general character of the student's work is closely watched. The charge for tuition is $200 per annum, with no fees unless a microscope is rented; that fee is $5 a year. The Dean is Dr. William H. Howell, 232 W. Lanvale St., Baltimore. Total registration in 1901-2 was 229; graduates, 123. The tenth session begins Oct. 7, 1902, and ends June 15, 1903.

Maryland Medical College.—This school was organized in 1898, and has a faculty of 14 professors, and 14 associates, lecturers, etc., 28 in all. The Franklin Square Hospital and a college dispensary furnish clinical material. The course of study covers three years of eight months each, but after October, 1902, all students matriculating will be compelled to take a four years' course. A matriculation fee of $5 and total laboratory fees for the three years of $50 are charged; the tuition for full course is $75 each year. The Dean is Dr. J. Wm. Funck, 101 N. Fulton Ave. Total registration for 1901-2 was 128; graduates, 39. The fifth session begins Oct. 1, 1902, and closes in May, 1903.

MASSACHUSETTS.

Massachusetts, population 2,805,346, has four medical colleges: Medical School of Harvard University, Boston University School of Medicine, College of Physicians and Surgeons, and Tuft's College Medical School. They are all situated in Boston, a city of 500,892 inhabitants, and enjoy in common the following clinical advantages: The Massachusetts General Hospital, in which during the past year 5086 patients were treated in the wards and 31,003 in the out-patient departments; the

Boston City Hospital, where during that time 8719 ward patients and 22,640 out-patients were treated, and the Massachusetts Charitable Eye and Ear Infirmary, which furnished treatment for 22,349 patients during the past year. Library facilities are good. Board and lodging can be obtained for from $5 to $7 per week.

Boston.

MEDICAL SCHOOL OF HARVARD UNIVERSITY.—This was organized in 1872 as the Medical Department of Harvard University, and has a faculty composed of 23 professors, 12 associate and assistant professors, and 1 curator, a total of 36. Besides the clinical advantages mentioned, the Boston Lying-in Hospital, the Boston Dispensary, where 43,918 patients were treated last year; the Infants' Hospital, the Children's Hospital, Long Island Hospital, containing 250 beds, and the Marine Hospital all furnish excellent opportunity to the student for clinical study. Students are also permitted to visit the Free Hospital for Women and Carney Hospital on application to the physicians on duty. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons, of suitable age and attainments, as may be admitted by special vote of the faculty in each case." Each candidate is required to hand in the original note-book in which he recorded the work performed by him in qualitative analysis, and also to pass a written examination in theoretical and descriptive chemistry. If conditioned in chemistry one year is allowed in which to remove the condition. The laboratories and lecture rooms offer ample facilities and the equipment is good; special facilities are open to those desiring to pursue advanced or original work. The course of study covers four years of nine months each; the course is graded, and each correlated group as taken up presents sufficient variety to avoid monotony. A series of written, oral and practical examinations are distributed throughout the course of study. Fees: Matriculation, $5; for the first three years, $200 each, and for the last year, if the three previous years have been taken in this school, $130; total of other fees charged is $22. The Dean is Dr. William L. Richardson, 688 Boylston St. Total registration for 1901-2 was 496; graduates, 167. The 121st session begins Sept. 25, 1902, and ends June 24, 1903.

BOSTON UNIVERSITY SCHOOL OF MEDICINE.—Homeopathic. This school was organized in 1873; in 1874 the New England Female Medical College, founded in 1848, was merged into it. The faculty includes 20 professors, 20 associates and lecturers, and 18 instructors and assistants, a total of 58. Clinical material is furnished by the Massachusetts Homeopathic Hospital, containing 225 beds, a dispensary, a maternity hospital, and the Westborough Insane Hospital; 800 patients. Candidates who have taken their degree in arts, philosophy or science, are not examined; all others are examined in English, Latin, French or German or history, mathematics, physics and chemistry. The instruction is graded and covers a period of four years, eight months each. Total fees for the first year are $105; for the second and third, $125 each, and for the last year, $155. The Dean is Dr. John P. Sutherland, 295 Commonwealth Avenue. Total registration for 1901-2 was 125; graduates, 23. The thirtieth session opens Oct. 2, 1902, and closes June 3, 1903.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1880, and has a faculty of 21 professors, and 15 lecturers and assistants, a total of 36. Clinical facilities are furnished by the North End Hospital and Dispensary, Union General Hospital, and the city and state institutions. This school is a member of the Association of American Medical Colleges. The course of study covers graded work for four years of eight months each. The total fees for the first year are $100, and for each of the other years about $110, with a graduating fee of $30. The Registrar is Dr. John H. Jackson, 155 Franklin St., Fall River. Total students registered 1901-2, 131; graduates, 9. The twenty-third session begins Sept. 25, 1902, and ends June 26, 1903.

TUFTS COLLEGE MEDICAL SCHOOL.—This school was organized in 1893 as the Medical Department of Tufts College. It has a faculty of 16 professors, 6 assistant professors and 31 lecturers, instructors and assistants, a total of 53. Clinical material is furnished by the Boston Dispensary, Cambridge Hospital, St. Elizabeth's Hospital, Carney Hospital and the college dispensary; the student has also the advantages derived from an out-department in connection with the Boston Dispensary. "Graduates of a high school, college or university, and students having certificates of entrance to a college or university, or holding the state of New York Regents' certificate," also certain approved preparatory school graduates, are admitted without examination; all others must pass an examination in English, Latin, physics and mathematics, including arithmetic, elementary algebra and plane geometry. The laboratories and lecture rooms are ample in their equipment and capacity. Teaching is carried on by means of lectures, recitations and practical work in the laboratories and clinics; frequent examinations are held during a course and a final examination on completing the subject. Graded instruction covering four years of eight months each makes up the full course. The total fees are $125 each year; dissecting material is furnished at cost. The Dean is Dr. Harold Williams, 528 Beacon St. Total number of students for 1901-2 was 335; graduates, 35. The tenth session begins Oct. 2, 1902, and ends May 28, 1903.

MICHIGAN.

Michigan, population 2,420,982, has seven medical colleges. Two of these, University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a town of 14,509 people. Board and lodging cost from $2.50 to $5 a week. Detroit, a city of 285,704 inhabitants, contains three medical colleges, as follows: Detroit College of Medicine, Detroit Homeopathic College and the Michigan College of Medicine and Surgery. Board and room can be obtained for $3 a week upwards. Grand Rapids Medical College is located in Grand Rapids, population 87,565, and here the cost of room and board is from $3 to $3.50 a week. The other school, Saginaw Medical College, is located in Saginaw, a city having a population of 42,345. Board and lodging can be procured for from $3 to $4.50 a week.

Ann Arbor.

UNIVERSITY OF MICHIGAN, DEPARTMENT OF MEDICINE AND SURGERY.—This department of the state university was organized in 1850, and has a faculty composed of 17 professors and junior professors, 15 associates and lecturers, and 35 instructors, assistants, etc., a total of 67. The University Hospital together with the lying-in department furnish the clinical facilities. There is now in process of erection a large ward to be known as the Palmer Ward, and also a psychopathic ward to accommodate 40 patients. The requirements for admission provide that the applicant, either by certificate or examination, show a sufficient knowledge of the following: English grammar, rhetoric and composition; United States and general history; algebra, through quadratics, plane and solid geometry and plane trigonometry; physics, biology and chemistry, these subjects to be accompanied by laboratory work; German or French, and Latin. The laboratories and their equipment are good, and the training in them and in didactic work is thorough. A large building, now nearing completion, and to be used for laboratory instruction and investigation, will be ready for occupancy at the beginning of the next session. This school is a member of the Association of American Medical Colleges. The curriculum embraces four years of nine months each. A combined course leading to degrees in both arts and medicine in six years is offered. The total fees for Michigan students for the entire course of four years is about $300, and for others $350. The Dean is Dr. Victor C. Vaughan, Ann Arbor. Total registration for 1901-2 was 508; graduates, 84. Next session begins Sept. 23, 1902, and will end June 18, 1903.

HOMEOPATHIC COLLEGE, UNIVERSITY OF MICHIGAN.—This department of the University was organized in 1875 and has a faculty of 6 professors, 3 assistants and 2 non-resident lecturers; the remainder of the teaching force utilized is that of the other departments of this University. The Homeopathic Hospital, containing 140 beds, furnishes material for clinical teaching. The course covers four years of nine months each. The total fees for Michigan students are about $240 for the four years, and for other students about $295. The Dean is Dr. W. B. Hinsdale. Total enrolment for 1901-2 was 55; graduates, 8.

Detroit.

DETROIT COLLEGE OF MEDICINE.—This school was formed in 1885 by the union of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, established 1880. The faculty embraces 21 professors, 44 lecturers, instructors, etc., and 30 clinical professors, a total of 95. Clinical facilities are offered by the following hospitals: St. Mary's and Harper, each of which contain a free dispensary; Woman's, St. Luke's, the Children's Free Hospital and the House of Providence. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The work includes laboratory, didactic and clinical study. Fees: Matriculation, paid once, $5; tuition, each term, $65; hospital and laboratory tickets, each $10; and diploma fee $30. The secretary is Dr. H. O. Walker. Total enrolment for 1901-2 was 242; graduates, 48. The next session begins Sept. 24, 1902; and will close May 7, 1903.

MICHIGAN COLLEGE OF MEDICINE AND SURGERY.—This school was organized in 1888, and has a faculty of 17 professors and 13 assistants, 30 in all. Clinical facilities are offered by a college dispensary, the Emergency Hospital and Detroit Eye and Ear Infirmary. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of seven months each. Fees: For the first two years, $85 each; third year, $70, and $95 for the fourth year. The Dean is Dr. Hal. C. Wyman, 46 W. Adams Ave., Detroit. Total registration for 1901-2 was 75; graduates, 13. The fifteenth session begins Sept. 18, 1902, and will end May 1, 1903.

DETROIT HOMEOPATHIC COLLEGE.—This was organized in 1899, and has a faculty of 37. Grace Hospital and a college dispensary are available for study of clinical cases. Unless possessing certificate of an equal amount of work completed, applicants for admission will be examined in English, arithmetic, history, geography and elementary Latin. The course embraces work for four years of seven months each. Fees: First year, $92; second, $85; third, $70, and $90 for the fourth year. The Dean is Dr. D. A. MacLachlan. Total enrolment for 1901-2 was 45; graduates, 6. The next session begins Sept. 24, 1902, and will close April 21, 1903.

Grand Rapids.

GRAND RAPIDS MEDICAL COLLEGE.—This was organized in 1897 as a three-year school, but the catalogue shows that all students matriculating after Jan. 1, 1901, will be compelled to take a four-year course of six months each. The faculty is made up of 21 professors and 6 assistants, in all 31. Clinical cases in the U. B. A. Hospital, St. Mary's, Woman's Butterworth hospitals, and St. John's Orphan Asylum and a college dispensary are available for study. The total fees are about $65 for each year. The Dean is Dr. C. H. White. Total enrolment for 1901-2 was 73; graduates, 47. Next session opens Oct. 1, 1902, and closes June 1, 1903.

Saginaw.

SAGINAW VALLEY MEDICAL COLLEGE.—This school was organized in 1896; it has a teaching force of 30. Clinical material is supplied by a college hospital and a college dispensary. Education equivalent to graduation from a recognized high school is required for admission. The course covers four years of seven months each. Fees: Matriculation, paid once, $5; tuition, each year, $50; laboratory and hospital and dissecting ticket each, $10, and graduation fee, $25. The Secretary is Dr. W. B. Cornell, Saginaw. Total enrolment for 1901-2 was 100; graduates, 41.

MINNESOTA.

Minnesota, population 1,751,394, contains three medical colleges: College of Homeopathic Medicine and Surgery, Hamline University College of Medicine, and College of Medicine and Surgery. They are all situated in Minneapolis, a city with a population of 202,718, and owing to its proximity to St. Paul, the following clinical advantages are available to them: City Hospital, Minneapolis; City Hospital, St. Paul; St. Luke's and St. Joseph's hospitals, both in St. Paul. The average cost of board and lodging is $20 a month. An agreement as to requirements for admission has been entered into between the University of Minnesota and Hamline University. They are (a) proof that the candidate has completed work in English composition and rhetoric; history, both ancient and modern; physiology, physics, algebra, geometry, and Latin equal to one year's work, or (b) ability to pass a satisfactory examination in these subjects.

Minneapolis.

College of Medicine and Surgery.—This is a department of the University of Minnesota and was organized in 1883. Until 1883 its work was only to examine for the degrees of B.M. or M.D., but at that time, with the absorption of the Minnesota Hospital Medical College and the St. Paul Medical College, it was reorganized and its present function assumed. Its faculty is made up of 26 professors, 10 clinical professors, 23 instructors and lecturers, and 22 assistants, a total of 81. Besides the clinical advantages enjoyed in common with other schools, St. Mary's, St. Barnabas and Asbury Methodist hospitals, the City and County hospitals of St. Paul and the St. Paul Dispensary, as well as the college dispensary, all furnish valuable material for clinical study. This college is a member of the Association of American Medical Colleges. The medical buildings, four in number, offer good laboratory and lecture-room facilities, and the equipment is all that is needed for thorough instruction. The curriculum covers four years of nine months each and the work is carefully graded. The total fees for each year is $100. The Dean is Dr. Parks Ritchie, Minneapolis. Total number of students registered for 1901-2 was 362; graduates, 61. The next session opens Sept. 17, 1902, and closes June 4, 1903.

Hamline University College of Medicine.—This was organized in 1883. Its faculty is composed of 24 professors, 6 associate and clinical professors, and 17 instructors and assistants, a total of 47. The laboratories and lecture rooms are large, well lighted and supplied with all the necessary equipment. Besides the hospitals mentioned, clinical work is offered to the student in City Hospital, Asbury Methodist Hospital, St. Barnabas and St. Mary's Hospitals in Minneapolis, Bethesda Hospital, City and County, and St. Joseph's, in St. Paul, and the college dispensary. This school belongs to the Association of American Medical Colleges. The course of study covers graded work for four years, nine months making a year. Total fees, first year, $85; second year, $87.50, and for each of the last two, $80. The Dean is Dr. L. M. Crafts, Minneapolis. Total number of students 1901-2 was 139; graduates, 34. The next session begins Sept. 17, 1902, and ends June 11, 1903.

College of Homeopathic Medicine and Surgery.—This is a department of the University of Minnesota and was organized in 1888. The faculty comprises 15 professors and 14 assistants, 29 in all. The primary branches are taught by the professors of the College of Medicine and Surgery. The course is graded, extending over four years of eight and one-half months each. The total fees for the first two years are $100 each, and $80 each for the last two years. The Dean is Dr. Alonzo P. Williamson, Minneapolis. Total number of students registered in 1901-2 was 21; graduates, 3. The next session opens Sept. 16, 1902, and closes June 5, 1903.

MISSOURI.

Missouri, population of 3,106,665, has fifteen medical colleges. St. Louis, population 575,238, contains six of these, viz.: St. Louis College of Physicians and Surgeons, American Medical College, Homeopathic Medical College of Missouri, Marion-Sims-Beaumont College of Medicine, Washington University Medical Department, and Barnes Medical College. Board and lodging can be procured for from $3.50 to $5 a week. Kansas City, with 163,752 inhabitants, has six colleges, namely: Kansas City Medical College, University Medical College, the Hahnemann Medical College of Kansas City, Woman's Medical College, Medico-Chirurgical College and Eclectic Medical University. Room and board can be obtained in this city for from $3 to $5 a week. Ensworth Medical College and Central Medical College are located in St. Joseph, population 102,979; board and room can be had for from $2.50 to $5 a week. The Department of Medicine of the University of Missouri is at Columbia, a town of 5651. Board and lodging can be obtained at Columbia for from $2 to $5 a week.

St. Louis.

St. Louis College of Physicians and Surgeons.—This school was organized in 1878, and has a faculty of 21 professors, 19 lecturers, demonstrators, and clinical instructors, and 4 special lecturers, a total of 44. The resources for clinical instruction are Jefferson Hospital, which is open to students of this college only; City Hospital, with 600 beds; Female Hospital, having 250 beds; City Insane Asylum; City Poorhouse and the college dispensary. This college is a member of the Association of American Medical Colleges. The laboratory and lecture-room space and the equipment are ample. The course of study covers four years of seven months each, and is graded. Total fees for the first year are $70, second $60, and third $60, and $75 for the fourth year. The Dean is Dr. Waldo Briggs, 1405 Olive St. Total number of students registered, 1901-2, was 280; graduates, 50. The twenty-fourth session begins Sept. 16, 1902, and ends April 9, 1903.

American Medical College.—Eclectic. This was organized in 1873, and has a faculty of 18 professors and 15 clinical instructors, a total of 33. Metropolitan Hospital, containing 40 beds, St. Louis City Hospital and a college dispensary supply ample clinical material. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of seven months each. The total fees are: tuition $75 per year, dissecting material $5 per year for three years, final examination and graduation fee $25. A scholarship, including four years, $250, paid $100 first year, $100 second year, $50 third year. If paid cash in advance, $240. Total registration for 1901-2 was 69; graduates, 14. The Dean is Dr. E. Lee Standlee. The present session opens Sept. 22, 1902, and closes April 22, 1903.

Homeopathic Medical College of Missouri.—This was organized in 1857 and has a faculty of 26 professors and 5 assistants, total 31. Clinical facilities are offered by the City Hospital, Children's Free Hospital and a college dispensary. The curriculum covers four years of seven months each. Fees: First year, $80; second, $75; third, $60, and $85 for the fourth year. The Dean is Dr. W. B. Morgan. Total registration for 1901-2 was 67; graduates, 12. The next session opens Sept. 22, 1902, and closes April 9, 1903.

Marion-Sims-Beaumont Medical College.—By the union of Marion-Sims, organized in 1890, and Beaumont Hospital Medical College, organized in 1886, the present school was founded. The faculty is composed of 38 professors, 33 lecturers and assistants, and 5 demonstrators, a total of 76. Clinical facilities are offered by Alexian Brothers' Hospital, with 250 beds; Rebekah Hospital, having a capacity for 50 patients; Josephine Hospital, 50 beds; Mt. St. Rose Throat and Chest Hospital, 150 beds; Good Samaritan Hospital, 50 beds; St. Mary's Infirmary, containing 150 beds; the City Hospital and Insane Asylum, each with a capacity of 600 patients. Grand Avenue Dispensary also furnishes good material for practical instruction. This school is a member of the Association of American Medical Colleges. The buildings afford ample laboratory and lecture-room space and they are well equipped. The course of study embraces laboratory and clinical instruction, with recitations and lectures. The curriculum covers four years of seven months each. The total fees for the first year are $80; for the second and third, $75 each, and $100 for the fourth. The Secretary is Dr. H. W. Loeb. Total number of students registered for 1901-2 was 488; graduates, 55. The next session opens Oct. 1, 1902, and closes May 1, 1903.

Washington University Medical Department.—This school was organized in 1891 from the St. Louis Medical College, which was founded in 1842. In 1899 the Missouri Medical College, organized in 1840, was added. The faculty comprises 36 professors, 19 clinical professors and lecturers, and 5 instructors, a total of 60. Clinical material is furnished by the St. Louis Mullanphy Hospital, St. John's Hospital, Polyclinic Hospital, Bethesda Hospital and O'Fallon's Dispensary. In addition to these, the City Hospital, Female Hospital, Insane Asylum and Poorhouse, are used in common with the other schools. The requirements for admission are those of the Association of American Medical Colleges. The college buildings, of which there are two, furnish good laboratory and lecture-room facilities. The course is four years of seven and one-half months each, and the system of study embraces laboratory, didactic and clinical teaching. The total fees for the first year are $121; second, $105, and for the third and fourth years, $100 each. The Dean is Dr. Robert Luedeking. Total registration of students for 1901-2 was 263; graduates, 43. The next session opens Sept. 25, 1902, and closes May 14, 1903.

Barnes Medical College.—This school was organized in 1892, and has a faculty of 24 professors, 9 lecturers and 11 assistants and instructors, a total of 44. The clinical advantages are those offered by Centenary Hospital, with 150 beds; City Hospital, the college dispensary and the outdoor obstetrical department. This college is a member of the Association of American Medical Colleges. The laboratories are well equipped and other facilities ample. The course of study includes graded work for four years of seven months each. The total fees for the first three years are $75 each, and $85 for the fourth year. The Secretary is Dr. Pinckney French, Century Bldg. Total registration for 1901-2 was 501; graduates, 78. The eleventh session opens Sept. 8, 1902, and closes April 9, 1903.

Kansas City.

Kansas City Medical College.—This was established in 1869, and has a faculty of 23 professors, and 22 lecturers, demonstrators, etc., in all 45. The clinical facilities are those of St. Joseph's Hospital, which also contains an out-patient department; the City Hospital, Bethany Hospital, Scarritt Hospital, St. Anthony's Home for Children and the college dispensary. This college is a member of the Association of American Medical Colleges. The building is large and well equipped, the course is graded and the classes in practical work are divided into small sections and required to personally conduct series of obstetric, medical and surgical cases as a condition of graduation. The curriculum embraces four years of seven months each. The total fees for the first three years are $75 each, and $85 for the fourth. The Dean is Dr. Robt. T. Sloan, Rialto Bldg. Total registration for 1901-2 was 111; graduates, 21. The thirty-fourth session begins Sept. 16, 1902, and ends March 25, 1903.

University Medical College.—This was organized in 1881 as the University of Kansas City Medical Department and in 1888 was reorganized under its present name. Its faculty comprises 21 professors, 11 adjunct professors and lecturers, and 14 assistants, a total of 46. Clinical material is furnished by the University Hospital, owned by the college, with 100 beds; the City Hospital, German Hospital, Home for the Aged, containing 147 beds; the Sisters' Hospital, Scarritt and St. Margaret's hospitals, the Children's Home, St. Joseph's Orphan Asylum, and the college dispensary and obstetric department. Instruction is given by means of lectures, recitations, demonstrations, and laboratory work and clinics. The school is a member of the *Association of American Medical Colleges*. The college building, which has been recently enlarged, furnishes ample accommodations for laboratories and lecture rooms. The course of study covers four years of six months each, and the work is graded. The total fees for each of the first two years are $80, for the third $60, and $85 for the fourth year. The Dean is Dr. Samuel C. James, Bryant Bldg. The total number of students registered in 1901-2 was 225; graduates, 27. The twenty-second session begins Sept. 9, 1902, and ends March 27, 1903.

Kansas City Hahnemann Medical College.—*This school was* formed by the union of the Kansas City Homeopathic Medical College, organized in 1888, and the Kansas City University College of Homeopathic Medicine and Surgery. It has a faculty of 32. The City Hospital, Homeopathic Hospital, the Sanitarium, Scarritt, University, Women's and Children's, German, Bethany and Children's hospitals are open to its students for clinical study. The college dispensary and clinics also supply clinical material. Applicants for admission must show by diploma, certificate or examination that they have a sufficient knowledge of English, arithmetic, geography, United States history, and Latin equal to one year's work. The course covers four years of seven months each. Total registration for 1901-2 was 72; graduates, 10. The fifteenth session begins Sept. 9, 1902, and closes April 9, 1903. The Dean is Dr. S. H. Anderson, 1214 Main St.

Woman's Medical College.—This school was organized in 1895, and has a faculty composed of 33 professors, 11 lecturers and assistants, a total of 44. Material for clinical study and demonstration is furnished by St. Joseph's, Scarritt, German, Sisters', Agnew, St. Margaret's and City hospitals, and the college dispensary. The requirements for admission are those of the Association of American Medical Colleges. The course of study embraces graded work for four years of seven months each. The total fees for the first year are $68; second, $60; third, $55, and $80 for the fourth year. The Dean is Dr. Nannie P. Lewis, 1219 Wyandotte St., Kansas City. Total number of matriculants for 1901-2 was 216; graduates, 6. The eighth session opens Sept. 17, 1902, and closes March 26, 1903.

Medico-Chirurgical College.—This school was organized in 1897 as the Kansas City College of Medicine and Surgery of Kansas City, Kan., and was reorganized the following year under its *present name. Its faculty embraces a total of 41. Clinical facilities* are furnished by the hospitals of Kansas City used in common by the medical colleges, and a college dispensary. The course *covers four years of six months each. The fees are: For the first* year, $70; second, $65; third, $55, and $75 for the fourth year. The Dean is Dr. George O. Coffin, 400 New Ridge Building. Total registration for 1901-2 was 87; graduates, 13. The *present session* opens Sept. 17, 1902, and closes March 20, 1903.

Eclectic Medical University.—This was organized in 1898 *and has 20 in its faculty. The curriculum covers four years of* six months each. Fees, about $70 each year, with a graduation fee of $15. The Dean is Dr. Theodore Doyle. Total students for 1901-2 was 49; *graduates, 12. The next session begins Sept.* 15, 1902, and ends March 13, 1903.

Columbia.

Department of Medicine of the University of the State of Missouri.—This department was organized at Columbia ni 1872. The *faculty includes* 12 professors, 18 assistants, lecturers, etc., a total of 30. Clinical facilities are supplied by the Parker Memorial State Hospital and the Boone County Infirmary. A new $40,000 building for the medical laboratories has just been completed and has excellent equipment. Special emphasis is laid on thorough training in the scientific branches which constitute the foundation of medicine. Four years' course, nine months each, *carefully graded.* The University offers also a combined course of six years, conferring degrees in both arts and medicine. The entrance requirements are a diploma from a good high school, or the full equivalent. There is no charge for tuition, the only expense being a library fee of $5 each year, and small laboratory fees. The Dean is Dr. A. W. McAlester. Total registration of students for *1901-2* was 90 (no graduates). The next session opens Sept. 9, 1902, and closes June 3, 1903.

St. Joseph.

Ensworth Medical College.—This was organized in 1888, and has a faculty of 19 professors and 12 lecturers and assistants, 31 in all. St. Joseph's Medical Hospital, with 250 beds; City Hospital, containing 40 beds; the State Hospital No. 2, which is open to the students once a week, and a college dispensary furnish clinical material. Applicants for *admission* must show by certificate or examination, that they possess a sufficient knowledge of English, arithmetic, algebra, physics and Latin equal to one year's instruction. The building furnishes ample laboratory and lecture-room facilities. The curriculum covers a graded course of four years of six months each. The fees are about $55 each for the first three years, and $75 for the fourth year. The Dean is Dr. Jacob Geiger, St. Joseph. Total enrolment for 1901-2 was 80; graduates, 14. The present session opened Sept. 1, 1902, and closes March 1, 1903.

Central Medical College.—This school was organized in 1894, and has a faculty made up of 16 professors and 14 lecturers, in all 30. The Methodist and St. Joseph's hospitals, State Hospital No. 2, and the City and County hospitals are available for clinical study; a college dispensary also supplies clinical material. The requirements for admission are the possession of a certificate for work completed, or an examination. The curriculum embraces four years of six months each. Fees: First year, $55; second, $50; third, $50, and $75 for the fourth year. The Secretary is Dr. T. E. Potter. Total enrolment for 1901-2 was 82; *graduates, 11.* The eighth session began Sept. 1, 1902, and will end March 1, 1903.

NEBRASKA.

Nebraska, population 1,066,300, has three medical colleges: Omaha Medical College, and John A. Creighton Medical College, in Omaha (population 102,555); and Lincoln Medical College, at Lincoln (population 40,169).

Omaha.

University of Nebraska College of Medicine.—This was organized in 1881 as Omaha Medical College. The name was changed this year and, *as soon as practicable, the first two years' work will* be done at the University at Lincoln. The last two years will continue to be conducted at Omaha, population 102,555. The faculty is composed of 28 professors, 18 adjunct professors and lecturers, a total of 46. The Douglas County Hospital, accommodating 300 patients; Bishop Clarkson Memorial Hospital, Immanuel Hospital, the Omaha Methodist Hospital and the college dispensary furnish good material for clinical study and demonstration. This college is a member of the Association of American Medical Colleges. The college building is well adapted for its purpose and the laboratories and lecture rooms are commodious and completely equipped. The course of work embraces graded studies covering four years of eight months each. The method of instruction is made up of didactic and clinical lectures, demonstrations, quizzes and laboratory work. The total fees for the first two years are $80 each, and $85 for each of the last two years. Board and lodging can be obtained for from $3 to $5 a week. The Secretary is Dr. Ewing Brown, Omaha. Total number of students registered in 1901-2 was 153; graduates, 38. The twenty-second session begins Sept. 10, 1902, and will end May, 1903.

John A. Creighton Medical College.—This school, organized in 1892, is the Medic[illegible] University, and has a faculty of 27 [illegible] lecturers, and 7 assistants, a total of [illegible] are those of St. Joseph's Hospital, containing 300 beds and having a clinical amphitheater connected with it; St. Bernard's Hospital, with 160 beds; Douglas County Hospital, Presbyterian Hospital, and the college dispensary; the material is abundant and varied. The school is a member of the Association of American Medical Colleges. The building, which was completed in 1898, contains excellent facilities for laboratory and lecture-room work, and the equipment is good. In the methods of instruction, including clinical, didactic and laboratory work, special emphasis is laid on practical work. The course of study embraces four years of eight months each. The total fees for the first two years are $80 each, and $85 for each of the last two years. The Dean is Dr. D. Bryant, McCague Bldg. Total number of students registered in 1901-2 was 151; graduates, 37. The tenth session opens Sept. 23, 1902, and closes May 1, 1903.

Lincoln.

Lincoln Medical College.—Eclectic. This was organized in *1889 and has a faculty of 25. The City Hospital and the college* dispensary furnish clinical material. The requirements for admission are those of the National Confederation of Eclectic Medical *Colleges, of which this college is a member. The course of study* covers four years of thirty-two weeks each. The total fees for the first year are $83; second, $78; third, $70, and $65 for the fourth year. The Dean is Dr. J. M. Keys, Omaha. Total number of students for 1901-2 was 98; graduates, 21. The present session begins Sept. 15, 1902, and ends May 21, 1903.

NEW HAMPSHIRE.

New Hampshire, population 411,588, contains one medical college.

Hanover.

Dartmouth Medical School.—This is the Medical Department of Dartmouth College, located in Hanover, population 1884. The school was organized in 1797. Its faculty is made up of 15 professors and 5 instructors, 20 *in all. The Mary Hitchcock Memorial* Hospital and a cottage hospital of 36 beds, supply the clinical material. Applicants for admission must possess an education at least equivalent to *graduation from a registered high school.* The laboratories afford good facilities for work in physics, biology, chemistry and physiology. The course covers four years of thirty-two weeks each. *Total fees for the first three years are* $110, and $135 for the fourth year. The Dean is Dr. William T. Smith. The total number of students registered for 1901-2 was 72; graduates, 15. The work for the entering class begins with that of the academic department, commencing Sept. 12, 1902, and closing April 9 and June 21, 1902; for the advanced classes it begins in July and ends in February.

NEW YORK.

New York State, population 7,268,894, has ten medical colleges. Seven of these, College of Physicians and Surgeons, Long Island College Hospital, New York Homeopathic Medical College, New York Medical College, Eclectic Medical College, Cornell University Medical College and the University and Bellevue Hospital Medical College are located in New York City, population 3,437,202. This city, with its hospitals and dispensaries, offers abundant clinical material. Board and lodging can be obtained for from $5 to $7 a week.

Albany Medical College is located in Albany, a city of 94,151 people, where board and room can be had for from $4 to $5 a week.

The University of Buffalo Medical Department is situated in Buffalo, population 352,387; here board and lodging can be obtained for from $3.50 to $5 per week.

The College of Medicine, Syracuse University, is in Syracuse, a city with 108,374 inhabitants. Board and lodging can be procured for from $3.50 a week upwards.

The laws of the state of New York require of the prospective student of medicine a preliminary education equivalent to that obtainable in a four years' course in any of the public high schools recognized by the regents as maintaining a satisfactory standard. Upon proof of at least this amount of education, a medical-student certificate will be issued by the state authorities. The colleges, therefore, have a common standard for the requirements of admission.

New York City.

College of Physicians and Surgeons.—This school was organized in 1807 and its present relation, that of Medical Department of Columbia University, was assumed in 1860. The faculty embraces 11 professors, 23 clinical and adjunct professors and 75 demonstrators, instructors, etc., a total of 109. The Vanderbilt Clinic, where 47,156 patients were treated during the year 1901, and which is equipped with all modern appliances for the study and treatment of disease, and Sloane Maternity Hospital, containing 116 beds, offer exclusive clinical advantages to students of this school. Besides these, Roosevelt Hospital, containing 238 beds; New York Hospital, with 150 beds; Bellevue, 850 beds; Presbyterian, 330 beds; St. Luke's, General Memorial, and New York Foundling hospitals, together with the Eye and Ear Institute, containing 40 beds, St. Mary's Free Hospital for Children, and the Hospital for the Ruptured and Crippled, all offer free clinical teaching to matriculants of this school. The laboratories, lecture rooms and amphitheaters are ample in equipment and accommodation; special provisions are made to equip each student thoroughly in each of the laboratories and thus make the work individual. The work is graded, covering four years of eight months each. The total fees for the first year are $205; for the second and third, $200 each, and $225 for the fourth year. The Dean is Dr. James W. McLane. Total registration for 1901-2 was 778; graduates, 145. The next session begins Oct. 6, 1902, and ends June 10, 1903.

Long Island College Hospital.—This was organized in 1858, and has a faculty of 11 professors, 13 adjunct and clinical professors and 45 lecturers, instructors, etc., a total of 69. Long Island College Hospital, containing 300 beds and being connected with a four-story maternity hospital; Polhemus Memorial Clinic, and Hoagland Laboratory, completely equipped with the most modern apparatus, are all a part of the college. Besides the clinical facilities furnished by these, members of the faculty attend at Kings County, St. John's, Brooklyn, Norwegian, Williamsburg, Methodist Episcopal and the Brooklyn Eye and Ear hospitals, where the students are offered opportunities for clinical study. Many of these also contain out-patient departments, thus permitting advanced students to attend personally to cases. Bedside instruction is also given in the wards. The course covers four years of thirty weeks each. Fees: First year, $190; second, $195; third, $160, and $145 for the fourth year. The Secretary is Dr. Joseph H. Raymond, New York City. Total registration, 1901-2, was 245; graduates, 31. The forty-fifth session opens Oct. 1, 1902, and closes May 15, 1903.

New York Homeopathic Medical College and Hospital.—This school, organized in 1861, has a faculty of 27 professors and 21 lecturers, instructors, etc., 48 in all. Flower Hospital, adjoining the college and having a completely equipped out-patient department, Metropolitan Hospital, New York Ophthalmic Hospital and the Laura Franklin Free Hospital for Children furnish the clinical facilities. The course covers four years of seven months each. Total fees for the first year, $110; second, $130; third, $125, and $155 for the fourth year. The Dean is Dr. W. H. King, 64 W. 51st St. Total number of students registered for 1901-2 was 106; graduates, 23. The next session begins Sept. 30, 1902, and ends May 7, 1903.

New York Medical College and Hospital for Women.—Homeopathic. This school was organized in 1863, and has a faculty of 21 professors, 3 adjuncts, and 14 lecturers, and 6 assistants, a total of 44. The college hospital and dispensary, the Memorial Hospital for Women, Metropolitan, Flower and the Laura Franklin Free Hospital for Children afford clinical material. The course covers four years of twenty-six weeks each. Fees: First year, $100; second, $110; third, $100, and $130 for the fourth year. The Dean is Dr. M. Belle Brown, 30 W. 51st St. Total registration for 1901-2 was 32; graduates, 6. The next session opens Sept. 30, 1902, and closes May 12, 1903.

Eclectic Medical College.—This was organized in 1865 and has a faculty of 12 professors and 23 lecturers, demonstrators, etc., 35 in all. A college dispensary, Beachonian Dispensary, Manhattan and Red Cross hospitals and Muncie Sanatorium supply clinical facilities. The work covers four years of seven months each. Total fees: First year, $125; second, $125; third, $125, and $155 for the fourth year. The Dean is Dr. George W. Boskowitz. Total registration for 1901-2 was 100; graduates, 7. The next session opens Sept. 24, 1902, and closes May, 1903. This school is a member of the National Confederation of Eclectic Medical Colleges.

Cornell University Medical College.—This department of Cornell University was established in 1898. The faculty is composed of 21 professors, 10 clinical professors, 36 instructors, and 67 clinical instructors and assistants, a total of 134. The City Hospital, having 1000 beds; Bellevue Hospital, New York Hospital, Presbyterian, Willard Parker and Reception, with 200 beds; New York Skin and Cancer; St. Francis, having a capacity of 230 beds; St. Vincent's, with 200 beds; the Manhattan Eye and Ear Hospital, and the Eye and Ear Infirmary, in addition to a large college dispensary, furnish the clinical resources; the material is abundant and varied. The first two years of the course are taken at New York or at Ithaca and the work is devoted to the fundamental scientific subjects. The last two years are spent mostly in practical and clinical work and the hospital advantages are utilized. The Loomis Laboratory, a five-story modern building, is well equipped and supplies ample practical laboratory facilities required in the advanced work. "The essential feature of the entire system is the division of the classes of the several years into small sections." Fees: First year, $190; second and third, $180 each, and $200 for the fourth year. The Dean is Dr. William M. Polk. Total registration for 1901-2 was 415; graduates, 53. The next session opens Oct. 1, 1902, and closes June 3, 1903.

University and Bellevue Hospital Medical College.—This is a department of the New York University, and was founded in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. The faculty is composed of 30 professors, 33 clinical professors and lecturers, and 50 instructors, demonstrators, etc., in all 113. Bellevue and City hospitals, hospitals of the Workhouse and Almshouse, Manhattan State Hospital for the Insane, Willard Parker and Reception hospitals, Riverside Hospital for Contagious Diseases, Randall's Island, Presbyterian, St. Luke's, St. Vincent's, General Memorial, Gouverneur, Columbus, Harlem, New York Foundling, and the Society for the Lying-in hospitals, the New York Eye and Ear Infirmary, and a large college dispensary are open to students of this school for a study of clinical cases. The Carnegie building, a new five-story structure adjoining the college, is devoted to laboratory instruction and investigation, and, with the other two large college buildings, affords good laboratory and lecture-room facilities. The course of instruction covers four years of eight months each. Actual clinical teaching, in conjunction with and founded on laboratory work, recitation and didactic teaching, is emphasized to the greatest possible degree. Fees: First year, $185; second and third, $180 each, and $195 for the fourth year. The Dean is Dr. Edward G. Janeway. Total registration for 1901-2 was 319; graduates, 48. The next session opens Oct. 1, 1902, and closes June 4, 1903.

Albany.

Albany Medical College.—This school was organized in 1838, and in 1873 it assumed its present relations, as Medical Department of Union University. The faculty is composed of 14 professors, 7 adjunct and clinical professors, and 30 lecturers, instructors and assistants, a total of 51. Albany, St. Peter's, Child's and County hospitals, South End Dispensary, Eye and Ear Infirmary and the Albany Hospital for Incurables, also the free dispensaries connected with each, are open to students for clinical study. The curriculum embraces graded work for four years of seven and one-half months each. Teaching is carried on in the laboratories, clinics and lecture rooms. Examinations are held twice a year in all subjects. Fees: Third year, $110, and $130 for each other year. The Dean is Dr. Albert Vander Veer. Total registration for 1901-2 was 154; graduates, 26. The next session opens Sept. 23, 1902, and closes May 5, 1903.

Buffalo.

University of Buffalo Medical Department.—This was organized in 1846 and has a faculty made up of 7 professors, 41 adjunct and clinical professors, and 31 lecturers, etc., a total of 79. Buffalo General Hospital, Hospital of the Sisters of Charity, Erie County and German hospitals and the German Deaconess' Hospital supply ample clinical material for study. A college dispensary, recently organized, is also of value in practical work. The buildings and hospitals are well equipped for clinical and laboratory work. Bedside instruction is insisted on and the senior students are permitted to assist in operations and give anesthetics. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The total fees are: First year, $455; second, $55, and $15 each for the third and fourth years. The Dean is Dr. Matthew D. Mann, 37 Allen St. Total registration for 1901-2 was 239; graduates, 38. The fifty-seventh session opens Sept. 29, 1902, and closes May 6, 1903.

Syracuse.

College of Medicine, Syracuse University.—This school was organized in 1872, as the Medical Department of Syracuse University. The faculty is composed of 16 professors and 29 lecturers, instructors, etc., in all 45. Clinical facilities are furnished by St. Joseph's Hospital, with a capacity of 200 patients; Hospital of the House of the Good Shepherd, Syracuse Hospital for Women and Children, Onondaga County Orphan Asylum, and the Syracuse Free Dispensary. The laboratories and amphitheaters are large and well equipped. This school is a member of the Association of American Medical Colleges. The curriculum embraces a four years' graded course, eight months making a school year. The total fees for each of the four years are $130. The Dean is Dr. Henry D. Didama, 424 S. Salina St. Total number of students registered for 1901-2 was 128; graduates, 9. The next session opens Oct. 7, 1902, and closes June 10, 1903.

NORTH CAROLINA.

North Carolina, population 1,893,810, has three medical schools. They are, Leonard School of Medicine, North Carolina Medical College, and the University of North Carolina Medical Department.

Raleigh.

Leonard School of Medicine.—This school was established in 1882 by the American Baptist Home Mission Society, for the purpose of training colored students of medicine. It is located in Raleigh, a city of 13,643, and has a faculty of 8 teachers. A free hospital and dispensary supply clinical material. A preliminary entrance examination is given to applicants not possessing a certificate or diploma of educational requirements. The course covers four years of six months each. The total fees for each year are $75. The dormitory plan is adopted generally, and board and room costs $2 a week. The Dean is Dr. James McKee. Total enrolment for 1901-2 was 106; graduates, 21. Next session opens Oct. 1, 1902, and closes April 14, 1903.

University of North Carolina Medical Department.—This school was organized in 1891, and formerly gave only the work of the first two college years, at Chapel Hill. In 1902 the course was extended to four years by the establishment of a department at Raleigh in which the last two years are given. Degrees will now be conferred and the faculty in the completed school of medicine numbers 25. It is a member of the Association of American Medical Colleges. The number of students enrolled in 1901-2 was 62. The President is Dr. F. P. Venable, Chapel Hill.

Davidson.

North Carolina Medical College.—This school was organized in 1893 and has a faculty of 16. It is located at Davidson, a village of 904 people, and a small hospital supplies the clinical facilities. The course covers but three years of eight months each. The requirements for admission claimed are those established by the Association of American Medical Colleges. Fees: First and second years, $85, and $100 for the third year. The President is Dr. J. P. Monroe. The total registration for 1901-2 was 55; graduates, 18. The session began Sept. 4, 1902, and closes May 11, 1903.

OHIO.

Ohio, population 4,157,545, has eleven medical colleges. Five of these, the Medical College of Ohio, Eclectic Medical Institute, Miami Medical College, Pulte Medical College and the Laura Memorial Woman's Medical College, are located in Cincinnati, a city of 325,902 inhabitants. The clinical advantages of Cincinnati are good; beside many smaller hospitals, the Cincinnati Hospital is open to the students for study. Board can be procured in Cincinnati for from $3 to $5 per week.

Cleveland, population 381,768, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. The City Hospital, with 275 beds, is used in common by them for clinical study. Board and lodging can be had for from $2.50 to $5 a week.

Columbus, population 125,560, contains two: Starling Medical College and Ohio Medical University. Board and lodging cost from $2.50 to $5 per week.

Toledo, with 131,822 people, has one medical school: Toledo Medical College. It has good clinical advantages. Board and room can be had for from $3 to $5 per week.

The laws of Ohio require that in order to practice medicine in this state, any student not possessing a diploma or certificate showing that he is possessed of the educational advantages required, must pass a satisfactory examination, under the direction of the State Board of Medical Registration and Examination, in the following subjects: English, including rhetoric and spelling; geography, arithmetic, algebra, physics, botany, United States history and Latin equal to a year's work. This is the standard adopted by all the medical colleges in the state.

Cincinnati.

Medical College of Ohio.—This is the Medical Department of the University of Cincinnati, organized in 1819, and has a faculty made up of 22 professors, 33 lecturers and assistants, a total of 55. Good Samaritan Hospital, with 150 beds; Cincinnati Hospital, with 550 beds, and a well-equipped college dispensary furnish clinical facilities. The buildings supply ample laboratory and lecture-room space, and their equipment is good. The course of study is graded and covers four years of seven months each. This school is a member of the Association of American Medical Colleges. The total fees are, for the first year, $105; for the second and third, $100 each, and $125 for the fourth year. Total registration of students for 1901-2 was 180; graduates, 47. The Dean is Dr. P. S. Conner, Cincinnati. The eighty-fourth session begins Oct. 1, 1902, and ends May, 1903.

Eclectic Medical Institute.—This school, organized in 1845, has a faculty of 29 members. The Seton Hospital, Cincinnati Hospital, and a college dispensary furnish clinical material. It is a member of the National Confederation of Eclectic Medical Colleges. The course covers four years of twenty-eight weeks each. The fees are $75 for each year, with a graduation fee of $25. The Dean is Dr. F. J. Locke, Newport, Ky. Total enrolment, 1901-2, was 143; graduates, 36. The next session begins Sept. 22, 1902, and closes April 14, 1903.

Miami Medical College.—This school was organized in 1852 and has a faculty of 23 professors and 27 lecturers and demonstrators, a total of 50. The clinical facilities are furnished by the Cincinnati Hospital and a college dispensary. This college is a member of the Association of American Medical Colleges. The curriculum embraces a four-year graded course of seven months each. The total fees are, for the first year, $115; for the second and third, $110, and $130 for the fourth year. The Secretary is Dr. J. C. Oliver, 628 Elm St. The total registration for 1901-2 was 97; graduates, 31. The next session opens Oct. 1, 1902, and closes May 6, 1903.

Pulte Medical College.—Homeopathic. This was organized in 1872 and has a teaching force of 19 professors and 19 assistants, 38 in all. Pulte Hospital, Cincinnati Hospital, Bethesda Hospital, Home of the Friendless and Foundlings, and a college dispensary supply clinical material. The curriculum covers four years of seven months each. Fees: First year, $80; for the second and third, $75 each, and $100 for the fourth. The Dean is Dr. J. D. Buck. Total enrolment for 1901-2 was 40; graduates, 10. The next session opens Oct. 1, 1902, and closes May 5, 1903.

Laura Memorial Woman's Medical College.—This school was formed in 1895 and has a faculty of 26. Presbyterian and Cincinnati hospitals and an extensive college dispensary supply material for clinical study. The out-patient department of the Presbyterian Hospital and interneship in the same hospital are open to students in this school exclusively. A special feature of instruction is a thoroughly equipped department in radiography. This college is a member of the Association of American Medical Colleges. The course embraces four years of study of seven months each. The total fees are $50 for each year. This includes all laboratory courses, which are ample in every facility. The Dean is Dr. John M. Withrow, Cincinnati. Total registration of students for 1901-2 was 26; graduates, 9. The next session opens Oct. 1, 1902, and closes May 5, 1903.

Cleveland.

Western Reserve University Medical College.—The Medical Department was organized in 1843. Its teaching faculty includes 18 professors, 21 lecturers and demonstrators, and 12 assistants, a total of 51. Clinical facilities are offered students of this school by Lakeside Hospital, having 250 beds; St. Vincent's Hospital, having about 135 beds; City Hospital, with 250 beds; St. Alexis Hospital, with 100 beds, and the Home of Maternity, with the dispensary service at Lakeside and Charity hospitals. The new clinical laboratory has recently been added, where a systematic course of instruction is given. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. The total fees are $125 for each year. The Dean is Dr. B. L. Millikin, 278 Prospect St. Total enrolment for 1901-2 was 126; graduates, 36. The next session begins Oct. 1, 1902, and ends June 23, 1903.

The Cleveland College of Physicians and Surgeons.—This was organized in 1863 as Charity Hospital Medical College, became the Medical Department of Wooster University in 1869 and became the Medical Department of Ohio Wesleyan University in 1896. The faculty is composed of 25 professors, 33 associates, lecturers and assistants, 58 in all. Cleveland General Hospital, City Hospital, St. Alexis Hospital, St. John's Hospital and a college dispensary are available for clinical teaching. This school is a member of the Association of American Medical Colleges. The school holds a continuous session, two terms of four months each constitute a year's work. The total fees for the first two years are $130 each, and for the last two years, $117 and $110, respectively. The Dean is Dr. N. S. Scott, 531 Prospect St. Total enrolment for 1901-2 was 86; graduates, 30. The next term opens Sept. 17, 1902.

Cleveland Homeopathic Medical College.—This school was founded in 1890 by a consolidation of Cleveland University of Medicine and Cleveland Medical College. The faculty includes 27 professors and 21 adjuncts, lecturers, etc., 48 in all. The clinical facilities are obtained from the Cleveland Homeopathic Hospital, and a college dispensary. The course embraces four years of thirty weeks each. Fees: First year, $110; second and third years, $105 each, and $125 for the fourth year. The Dean is Dr. Gaius J. Jones. Total number of students registered, 1901-2, was 112; graduates, 23. The next session opens Sept. 17, 1902, and closes April 15, 1903.

Columbus.

Starling Medical College.—This school was organized in 1847 and has a faculty composed of 13 professors and 16 lecturers, associates, etc., a total of 29. St. Francis Hospital, which is under the control of this faculty, Hawke's Hospital, of Mt. Carmel, the Lawrence Hospital for Women, and a college dispensary are available for clinical study. This college is a member of the Association of American Medical Colleges. The work covers four years of seven months each. Fees: First year, $73; second, $71; third, $60, and $80 for the fourth year The Dean is Dr. Starling Loving. Enrolment for 1901-2 was 162; graduates, 32. The next session opens September, 1902, and closes April, 1903.

Ohio Medical University.—This school was organized in 1890 and has a faculty of 23 professors and 9 assistants, 32 in all. The Protestant Hospital, Ohio Penitentiary Hospital and a college dispensary provide material for clinical work. The amphitheaters and laboratories are well equipped. This school is a member of the Association of American Medical Colleges. The course is four years of seven months each. Fees: First year, $86; second year, $79; third, $51, and $61 for the fourth year. The Dean is Dr. George M. Waters Total students for 1901-2 was 232; graduates, 61. The present session begins Sept. 17, 1902, and ends April 16, 1903.

Toledo.

Toledo Medical College.—This school was organized in 1882 and has a faculty of 18 professors, 15 lecturers and 6 assistants, in all 39. Toledo Hospital, St. Vincent's and Robinwood hospitals, Lucas County Infirmary Hospital, Toledo Hospital for the Insane, and a free dispensary supply good clinical facilities. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of seven months each. The fees are $75 for each year with a matriculation fee of $5, payable once. The Secretary is Dr Park L. Myers, 1921 Franklin Ave. Total enrolment for 1901-2 was 52; graduates, 10. The next session opens Sept. 25, 1902, and closes April 23, 1903.

OREGON.

Oregon, population 413,536, has two medical colleges: Medical Department Willamette University, and University of Oregon, Medical Department.

Salem.

Medical Department Willamette University.—This school is situated in Salem, a town of 4,258 people, and was organized in 1864. The faculty consists of 15 teachers. Clinical facilities for study are supplied by Salem Hospital, and a college dispensary. This school is a member of the Association of American Medical Colleges. The course embraces four years' work of six months each. Fees: First year, $110; second, $100; third, $75; and $50 for the fourth year. Board and lodging costs from $3 to $5 a week. The Dean is Dr. W. H. Byrd, Salem. Total enrolment for 1901-2 was 27; graduates, 5. The next session begins Oct. 1, 1902, and ends April 2, 1903.

Portland.

University of Oregon Medical Department.—This department of the State University was organized in 1887 and has a faculty of 15 professors and 11 special lecturers, a total of 26. It is situated in Portland, population 98,000. Good Samaritan and St. Vincent's hospitals, containing 200 and 350 beds, respectively, furnish good material for clinical study. The requirements for admission are those of the Association of American Medical Colleges. The college building is modern and well equipped, presenting ample teaching facilities. The course is four years of six months each. Fees: First year, $142.50; second, $107.50; third, $137.50, and for the fourth the only fee is $7.50 for examination fee. Board and room can be obtained for from $4 to $6 a week. The Dean is Dr. Simeon E. Josephi, Portland. Total number of students for 1901-2 was 80; graduates, 20. The next session opens Oct. 1, 1902, and closes April, 1903.

PENNSYLVANIA.

Pennsylvania, population 6,302,115, has six medical colleges. Of these Philadelphia, having a population of 1,293,697, contains five, as follows: University of Pennsylvania Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, and the Medico-Chirurgical College of Philadelphia. The clinical facilities of Philadelphia present abundant and varied material for study. Besides the individual hospitals connected with each of the schools the charity hospitals are open to all the students in common. Board and lodging costs from $4 a week upwards.

The other school, Western Pennsylvania Medical College, is situated in Pittsburg, a city of 321,616 people. The cost of board and lodging is from $4 to $6 a week.

A preliminary examination is required of all applicants for a license to practice medicine or surgery in the state. This examination is held at stated intervals by the State Examiners, and includes: (a) English composition, grammar and rhetoric; (b) mathematics, covering algebra and plane geometry; (c) elementary physics; (d) United States history, and (e) Latin equivalent to a year's study. Upon passing a successful examination a medical student certificate is issued to the applicant. This certificate will admit the possessor to matriculation in any medical college in the state.

Philadelphia.

University of Pennsylvania Department of Medicine.—This is the first medical college established in this country, having been organized in 1765 as the Medical Department of the College of Philadelphia; the first degrees were granted in 1768. When from the College of Philadelphia the University of Pennsylvania was organized in 1791, it became the Medical Department of the University, its present relation. The faculty is made up of 19 professors, 6 clinical professors, and 76 assistants, lecturers, etc., a total of 101. Abundant and varied clinical material is furnished by the University Hospital, where during 1900 there were 14,936 cases treated; Maternity Pavilion, with 50 beds; Philadelphia Hospital, containing 1000 beds; Pennsylvania, Children's and German hospitals, and the Southeastern Hospital and Dispensary. Special attention is paid to bedside instruction and to thoroughly practical work. Applicants for admission must furnish evidence of the education required to enter the academic department of the University. The buildings known as Medical Hall, Laboratory Hall and the Laboratory of Hygiene supply excellent laboratory and lecture-room facilities and they are well equipped. The course embraces study for four years of nine months each. The total fees for each year are $200 each, with a matriculation fee of $5 for the first year. The Dean is Dr. John Marshall. Total enrolment for 1901-2 was 542; graduates, 151. The next session opens Sept. 26, 1902, and closes on the third Wednesday in June, 1903.

Jefferson Medical College.—This school was organized in 1826, and has a faculty of 15 professors, 11 clinical and adjunct professors, and 58 lecturers, demonstrators, etc., a total of 84. Jefferson Hospital, together with its Maternity Department, are used exclusively by students of the school for clinical study. Bedside instruction is given daily to small sections of the senior class. In addition, the following hospitals are open for study of clinical cases: Pennsylvania, Philadelphia, St. Joseph's, German, Municipal and Wills Eye hospitals. This college is a member of the Association of American Medical Colleges. The course of study covers graded work of four years of eight months each. The laboratories are large and well equipped, a new five-story laboratory building having recently been added; the lecture rooms and amphitheaters are also ample. The tuition is $150 a year, with a matriculation fee of $5, paid but once. The Dean is Dr. James W. Holland. The total number of students for 1901-2 was 724; graduates, 140. The net session opens Oct. 1, 1902, and closes May 29, 1903.

Hahnemann Medical College and Hospital.—Homeopathic. This was organized in 1848 and has a faculty of 15 professors and 42 lecturers, instructors, etc., in all 57. Hahnemann College Hospital and Pennsylvania Hospital furnish material for clinical work. The requirements for admission are those established by the Intercollegiate Committee of the American Institute of Homeopathy. The work covers four years of thirty weeks each. Fees: For each year, $125; matriculation, $5; graduation, $30. Total number of students for 1901-2 was 269; graduates, 58. The Dean is Dr. Pemberton Dudley, Philadelphia. The next session begins Sept. 30, 1902, and will end May 14, 1903.

Woman's Medical College of Pennsylvania.—This school was organized in 1850, and has a faculty of 11 professors, 19 clinical and assistant professors, and 23 lecturers, etc., in all 53. Clinical facilities are offered exclusively to this college by the Woman's Hospital, West Philadelphia Hospital for Women. Other clinical advantages offered are those of the Pennsylvania, German, Children's and Philadelphia hospitals, Wills Hospital for Diseases of the Eye and the Philadelphia Lying-in Charity. This school is a member of the Association of American Medical Colleges. The lecture-room and laboratory equipment is good. The curriculum covers four years of eight months each. Fees: First year, $141.50; second, $138.50; third, $135.50, and $100.50 for the fourth year. The Dean is Dr. Clara Marshall. Total enrolment for 1901-2 was 157; graduates, 28. The fifty-third session begins Sept. 24, 1902, and will end May 20, 1903.

Medico-Chirurgical College of Philadelphia.—This school was organized in 1881 and has a faculty made up of 16 professors, 13 emeritus, clinical and associate professors, and 45 lecturers, demonstrators, etc., 74 in all. Opportunities for clinical study are offered exclusively to students of this school by the Medico-Chirurgical Hospital, with 130 beds; Children's Hospital, containing 40 beds, and a maternity hospital having 40 beds. In common with other schools the following are used: Philadelphia, Pennsylvania, German, Samaritan, St. Joseph's, St. Agnes', St. Mary's, Methodist and the Philadelphia Lying-in hospitals. This school is a member of the Association of American Medical Colleges. With new laboratories, lecture rooms and fine clinical amphitheater this college is amply provided and the equipment is good. The work embraces four years of eight months each. Fees: $150 per annum. The Dean is Dr. Seneca Egbert, 4814 Springfield Ave. Total enrolment for 1901-2 was 447; graduates, 87. The next session opens Oct. 1, 1902, and will close May 23, 1903.

Temple College Department of Medicine.—This department was opened in 1901 and has a faculty of 27. Besides the hospitals of Philadelphia, open to all students, Samaritan Hospital supplies clinical material. The course is five years of nine months each and instruction is given at night. The fees are $125 per year, matriculation, $5, paid once. The Dean is W. W. Fritz. Enrolment, 1901-2, was 35. The next session begins Sept. 15, 1902, and ends June 9, 1903.

Pittsburg.

Western Pennsylvania Medical College.—This is the Medical Department of the Western University of Pennsylvania, and was organized in 1886. The faculty is composed of 29 professors, and 39 associates, assistants, etc., 68 in all. Clinical material for study is furnished by a college dispensary, and the Emma Kaufman Clinic, Reineman Maternity Hospital, Mercy, South Side and St. John's hospitals. This school is a member of the Association of American Medical Colleges. Well-equipped laboratories provide ample facilities for individual work; the lecture-room space is sufficient. The course of study embraces graded work for four years of eight months each. Special attention is given to practical bedside work. The total fees are $130 for each year. The Dean is Dr. J. C. Lange. Total enrolment for 1901-2 was 327; graduates, 57. The next session begins Oct. 1, 1902, and will close May 28, 1903.

SOUTH CAROLINA.

South Carolina, population 1,340,316, has one medical college.

Charleston.

The Medical College of the State of South Carolina.—This is situated in Charleston, a city of 55,807 people, and was founded in 1823. The faculty is made up of 10 professors and 11 assistants, etc., 21 in all. The clinical facilities are those offered by the City Hospital, where surgical, obstetrical and medical instruction is given. Applicants for matriculation must show by certificate or examination that they possess the education required of second-grade teachers in the public schools. The course covers four years of six months each. The total fees for each of the first two years are $100, and $75 each for the last two. Board and room can be obtained for from $12 to $16 a month. The Dean is Dr. Francis L. Parker. Total enrolment for 1901-2 was 89; graduates, 4. The next session opens Oct. 1, 1902, and closes April, 1903.

TENNESSEE.

Tennessee, population 2,020,616, has ten medical colleges. Of these the Medical Department of the University of Nashville, Vanderbilt University Medical Department, University of Tennessee Medical Department, and Meharry Medical College are situated in Nashville, a city with a population of 80,865. The City Hospital, containing 100 beds, is used by all the schools in common for clinical study. Board and lodging cost from $3 to $4 a week. Knoxville, population 32,637, contains two colleges, Tennessee Medical College and Knoxville Medical College. The cost of room and board in that city is from $2.50 to $4 a week. Chattanooga Medical College and Chattanooga National Medical College are situated in Chattanooga, a city of 30,154 people. Board and lodging cost there from $1.50 a week upwards. There is one college, Memphis Hospital Medical College, located in the growing city of Memphis, population 102,320. Good board can be obtained for from $3 to $4 a week. The other school, the Sewanee Medical College, is located at Sewanee, a mountain town of 1200 people.

Nashville.

Medical Department University of Nashville.—This school, established in 1850, has a faculty of 14 professors and 13 lecturers, assistants, etc., in all 27. This school is a member of the Southern Medical College Association. The course of study covers four years of twenty-six weeks each. The total fees for each of the four years are $65. The Dean is Dr. William G. Ewing. Total enrolment for 1901-2 was 257; graduates, 34. The next session begins Oct. 1, 1902, anu ends April 2, 1903.

Vanderbilt University Medical Department.—This school was founded in 1874, and in 1895, when the present medical building was completed, the course was extended, the standard raised, and the present faculty, consisting of 15 professors and 20 associates, lecturers, etc., appointed. The school is a member of the Southern Medical College Association. The course covers four years of six months each. The total fees for the first three years are $105 each, and $130 for the fourth year. The Dean is Dr. William L. Dudley, Nashville. Total enrolment for 1901-2 was 160; graduates, 16. The next session begins Oct. 1, 1902, and ends April 3, 1903.

University of Tennessee Medical Department.—This was organized in 1876 as the Nashville Medical College; its present relations were assumed in 1879. The faculty is composed of 14 professors and 13 lecturers, assistants, etc., 27 in all. The school is a member of the Southern Medical College Association. The course of study includes work for four years of six months each. The total fees for each of the first three years are $90, and $65 for the fourth year. The Dean is Dr. Paul F. Eve, 614 Broad St. Total enrolment for 1901-2 was 162; graduates, 18. The next session begins Oct. 1, 1902, and ends April, 1903.

Meharry Medical College of Walden University.—Colored. This school was organized in 1876 as the Medical Department of Central Tennessee College, now Walden University, "for the purpose of furnishing to the colored people of the South an opportunity of obtaining a medical education." The faculty is made up of 9 professors and 11 instructors, demonstrators, etc., 20 in all. This school is a member of the Association of American Medical Colleges. The work embraces a four-year graded course, six months to the year. The total fees for the first three years are $40 each. and $50 for the fourth year. The Dean is Dr. G. W. Hubbard. Total registration for 1901-2 was 233; graduates, 55. The twenty-seventh session begins Sept. 3, 1902.

Knoxville.

Tennessee Medical College.—This school was organized in 1889, and has a faculty of 13 professors and 6 assistants, 19 in all. City General Hospital and a free dispensary supply material for a study of clinical cases. This school is a member of the Southern Medical College Association. The curriculum includes graded work for four years of six months each. Fees: First year. $75; second, $70; third, $67.50, and $94 for the fourth year. The Secretary is Dr. Henry J. Kelso. Total number of students for 1901-2 was 49; graduates, 23. The fourteenth session begins Oct. 1, 1902, and closes April 1, 1903.

Knoxville Medical College.—Colored. This school was established in 1900, following the discontinuance of the Medical Department of Knoxville College, organized in 1895. The teaching force comprises 11 professors. The City Hospital and a college dispensary supply clinical material. Applicants for admission not possessing a certificate of the necessary educational requirements "must pass a satisfactory examination." The course covers four years of six months each. Fees: First year, $42; second, $37 third, $30, and $40 for the fourth year. The Dean is Dr. E. L Randall. Total number of students for 1901-2 was 37; graduates, 3. The next session opens Dec. 1, 1902, and closes May 26, 1903.

Chattanooga.

Chattanooga Medical College.—This is the Medical Department of Grant University and was organized in 1889. The faculty is made up of 10 professors, and 22 demonstrators, instructors. etc., 32 in all. Clinical facilities are supplied by the wards of Erlanger Hospital, County Poor Asylum, free public dispensary of the college, and the City Physician's Office, which is maintained in the college building. The requirements for entrance are those of the Southern Medical College Association. The facilities have been increased by the completion of another four-story building at a cost of over $25,000, in which much new equipment has been installed. The course of work covers four years of six months each and is graded. The total fees for the first, third and fourth years are $75 each, and $85 for the second year. The Dean is Dr. E. A. Cobleigh. Total enrolment for 1901-2 was 252; graduates, 41 The fourteenth session begins Oct. 8, 1902, and ends April 13, 1903.

Chattanooga National Medical College.—Colored. This was organized in 1898. It has a teaching force of 18. The course covers four years of seven months each. The total fees are $50 each year with an additional graduation fee of $20. Total enrolment for 1901-2 was 26; graduates, 7. The Dean is Dr. T. W. Haigler 602 E. 8th St. The present session began Sept. 2, 1902, and ends March 28, 1903.

Memphis.

Memphis Hospital Medical College.—This school, organized in 1878, has a faculty of 10 professors and 18 assistants, beside quiz masters. Excellent clinical facilities are furnished by the City Hospital, Presbyterian Hospital, St. Joseph's Hospital and the East End Dispensary, the latter being located in the college building. The course includes graded work for four years of six months each. The total fees for the first three years are $75; for the fourth, $105. The Dean is Dr. W. B. Rogers. Total registration for 1901-2 was 687; graduates, 171. The twenty-third annual session will begin Nov. 1, 1902, and close April, 1903.

Sewanee.

Sewanee Medical College.—This is a three-year school, the Medical Department of the University of the South. It was organized in 1891 and has a faculty of 22. The college is a member of the Southern Medical College Association. The course has been three years of six months each, but beginning with 1902 four years will be required. The fees are $65 for each of the first two years, $55 for the third and $75 for the last year. The Dean is Dr. John S. Cain. Total enrolment for 1901-2 was 227; graduates 81. The eleventh session commenced May 1, 1902, and will close the last of January, 1903.

TEXAS.

Texas, population 3,048,710, has four medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 37,789 inhabitants. Good board and room can be procured for from $15 to $20 a month. The Medical Department of Fort Worth University is at Fort Worth, population 26,888. The cost of board and room in that city is from $12 to $15 a month. The other two colleges, University of Dallas Medical Department and Dallas Medical College, are situated in Dallas, population 42,638.

Galveston.

University of Texas Medical Department.—This department of the State University was organized in 1891 and has a faculty of 22. The John Sealy Hospital, also having an outdoor department, and St. Mary's Infirmary supply good material for clinical study. *The requirements for admission* are proof, either by certificate or examination, that the candidate is sufficiently proficient i English, *including* grammar, composition and rhetoric; mathematics through *plane geometry and* algebra including quadratics, and general history. The curriculum embraces graded work for four years of eight months each. Fees, *to residents of the state*: First year, $50; second and third *each $20*, and $5 for the fourth. Non-residents of the state are required to pay an additional fee of $50 each year. The Dean is Dr. Henry P. Cooke. Total registration for 1901-2 was 167; graduates, 13. The twelfth session begins Oct. 1, 1902, and ends May 30, 1903.

Fort Worth.

Medical Department of Fort Worth University.—This school was organized in 1894, and has a *faculty of 17 professors*, and 14 lecturers, assistants, etc., in all 31. Clinical facilities are supplied by St. Joseph's Hospital, with 200 beds; the Benevolent Home, containing 75 beds; the Delia Collins' Rescue Home, having 50 beds, and *a college dispensary*. The school is a member of the Southern Medical College Association. Instruction is carried on by laboratory, didactic and clinical study. The course covers four years of six months each. The total fees for each of the first three years are $75, and $100 *for the fourth.* year. The Dean is Dr. Bacon Saunders. The total enrolment for 1901-2 was 141; graduates, 17. The next session opens Oct. 1, 1902, and closes April 7, 1903.

Dallas.

University of Dallas Medical Department.—This school has completed its second year. *The faculty* numbers 27. Parkland Hospital, with 90 beds; St. Paul's Sanitarium, Good Samaritan, and Policlinic Infirmary and a college dispensary and hospital are utilized for clinical study. The course *covers four years* of six months each. The school is a member of the Association of Southern Medical Colleges. The fees *are $75 for each of the four* years, with a matriculation fee of $5, paid once, and a graduation fee of $25. The Dean is Dr. E. H. Cary. *Total registration* for 1901-2 was 98; graduates, 9. The third session opens Oct. 1, 1902, and closes April 1, 1903.

Dallas Medical College.—This school became the Medical Department of Trinity University in 1901 and has completed two sessions. It began as a three-year school but now requires four years *of six months each.* It has a faculty of 30 professors and 13 adjuncts and assistants. The Parkland Hospital with 90 beds; St. Paul Sanitarium, with 150 beds; *The Medical College* Hospital and College Dispensary *supply clinical material.* The requirements for admission are those of the Association of American Medical Colleges. Fees are $75 each year; *matriculation fee,* $5, payable but once; graduation fee. $25. The Dean is Dr. Hugh L. McNew. Total enrolment, 1901-2, was 91; graduates, 10. The third session begins Oct. 1, 1902, and ends April 1, 1903.

Physio-Medical College of Texas.—This new school has a *faculty of 26. The requirements for admission* are a diploma or its equal or an examination in English *grammar, arithmetic, elementary* physics, United States history, geography and Latin. The course is four years of twenty-six weeks each. The fees are, first year, $70; fourth year, $85; other years, $65. Enrolment, 1901-2, 20; graduates, 3. The next session opens Oct. 14, 1902, and closes April 16, 1903. The Secretary is Dr. R. L. Spann.

VERMONT.

Vermont, population *343,641*, has one medical school.

Burlington.

Medical Department, University of Vermont.—This school is located at Burlington, a town of 18,640 people; it was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 20 professors, and 14 adjuncts, instructors, etc., in all 39. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must show by certificate or examination sufficient knowledge of the following: English, including grammar, orthography and composition; geography, United States history, arithmetic and elementary physics. The laboratory and lecture-room space and equipment are good. The course of study embraces graded work for four years of six months each. The total fees for each of the first three years are $115, and $140 for the fourth year. Board and room costs from $3.50 to $5 a week. The Secretary is Dr. B. J. Andrews. Total registration of students for 1901-2 was 210; graduates, 32. The fiftieth session begins Jan. 2, 1903, and ends June 26, 1903.

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges. The University of Virginia Department of Medicine is situated in Charlotteville (population 6449). Board and room can be obtained for $18 a month and upward. The other two colleges, Medical College of Virginia and University College of Medicine, are located at Richmond (population 85,050). The clinical facilities are good. Board and room can be obtained for from $12 to $20 a month.

Charlotteville.

University of Virginia Medical Department.—This school was organized in 1825, and has a faculty of 27. A free dispensary and the new four-story hospital furnish clinical facilities. The requirements for admission are those of the Association of American Medical Colleges. The course is four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. Total enrolment for 1901-2 was 211; graduates, 53. The seventy-ninth session opens Sept. 15, 1902, and closes June 17, 1903.

Richmond.

Medical College of Virginia.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, and in 1854 the present name was assumed. The faculty is made up of 15 professors, and 21 lecturers, instructors, etc., a total of 36. Clinical material is furnished by the Old Dominion Hospital, Maternity Hospital, and the City Free Dispensary; an outside obstetric department also furnishes opportunities for clinical work. The magnificent new Memorial Hospital, which will be completed at about the opening of the session of 1902-3, will be under the exclusive control of this college for clinical purposes. The State Penitentiary, City Almshouse, and other public charities and asylums of the city, also afford opportunities for clinical work. This school is a member of the Southern Medical College Association. The buildings are large and contain well-equipped laboratories and amphitheaters. The course embraces four years of seven months each. The fees are $65 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins. Total registration for 1901-2 was 212; graduates, 13. The next session begins Sept. 30, 1902, and will end May 12, 1903.

University College of Medicine.—This school was organized in 1893 and has a faculty of 18 professors, 34 lecturers, assistants, etc., a total of 52. Good clinical facilities are furnished by Virginia Hospital, with a maternity department and annex which was built especially for the purpose of affording clinical instruction; Richmond Eye, Ear and Throat Infirmary, containing 34 beds; the City Hospital, and a college dispensary. Applicants for matriculation must show by certificate or examination to be possessed of a certain proficiency in English, mathematics and Latin. The laboratory and lecture-room space and equipment are ample, but the school lays especial importance on the careful instruction and guidance of each student. The curriculum covers four years of seven and one-half months each. The total fees are $85 for each year. The Dean is Dr. J. Allison Hodges, Richmond. Total enrolment for 1901-2 was 194; graduates, 8. The next session begins Sept. 30, 1902, and ends May 14, 1903.

WISCONSIN.

Wisconsin, population 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 285,315 people. Clinical facilities are furnished them in common by the County Hospital, with 175 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee.

Milwaukee Medical College.—This school was organized in 1893, and has a faculty of 22 professors, 7 associates, and 28 lecturers, instructors, etc., a total of 57. Good clinical material is furnished by Trinity, St. Mary's, and the County hospitals, Milwaukee Hospital for the Insane, and a college dispensary. This school is a member of the Association of American Medical Colleges. Ample laboratory and amphitheater facilities are afforded. The course covers four years of seven months each. The total fees are $120 each for the first three years, and $130 for the fourth year. The President is Dr. William H. Earles. Total number of students for 1901-2 was 184; graduates, 28. The ninth session begins Oct. 1, 1902, and will close May 4, 1903.

Wisconsin College of Physicians and Surgeons.—This college was organized in 1893, and has a faculty composed of 28 professors, and 23 associates, assistants, etc., a total of 51. St. Joseph's Hospital, containing 150 beds; Wisconsin Maternity Hospital, a college dispensary and the material used in common with the other school supply ample facilities for clinical study. The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped. The curriculum includes four years of eight months each. Fees: Matriculation, paid once, $5; general ticket $100; for the use of microscope, a fee of $2 is charged for each course. The Secretary is Dr. W. H. Washburn. Total enrolment for 1901-2 was 125; graduates, 19. The next session begins Sept. 30, 1902, and ends May 28, 1903.

OKLAHOMA.

Oklahoma, population 398,331, may have one medical college in the immediate future. A charter has been obtained, a partial faculty of 18 selected and plans laid to open Oct. 1, 1902. The name will be the Oklahoma City Medical College and it will be controlled by the rules of the Association of American Medical Colleges. The session will close April 1, 1903. The city of Oklahoma has a population of 10,037 and contains two hospitals, aggregating 100 beds.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The requirements for admission to be maintained by colleges belonging to this Association are as follows:

Section 1.—Each college holding membership in this Association shall require of each student, *before admission* to its course of study [illegible]um of which shall be as follows:

1. [illegible] some subject of general interest. This [illegible] by the student at the time of the examination, and should contain at least 200 words. It should be criticised in relation to thought, construction, punctuation, spelling, and handwriting.

2. In *Arithmetic*, such questions as will show a thorough knowledge of common and decimal fractions, compound numbers, and ratio and proportion.

3. In *Algebra*, such questions as will bring out the student's knowledge of the fundamental operations, factoring, and simple quadratic equations.

4. In *Physics*, such questions as will discover the student's understanding of the elements of mechanics, hydrostatics, hydraulics, optics, and acoustics.

5. In *Latin*, an examination on such elementary work as the student may offer, showing a familiarity usually attained by one year of study; for example, the reading of the first 15 chapters of Cæsar's Commentaries, and the translation into Latin of easy English sentences involving the same vocabulary.

Sec. 2.—In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official *certificates of reputable* literary and scientific colleges, academies, high schools, and normal schools, and also the medical student's certificate issued by any state examining board covering the work of the foregoing entrance examination.

Sec. 3.—Colleges, members of this Association, may allow students *who fail in one or more branches* in this entrance examination the privilege of entering the first-year course, but such students shall not be allowed to begin the second course until the entrance *requirements are satisfied.*

Sec. 4.—Colleges, members of this Association, are free to honor official *credentials issued by medical colleges of equal requirements,* except in the branches of study embraced in the last year of their own curriculum.

Sec. 5.—Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least *four courses* of medical instruction, each course of at least six months' duration, no two courses of which shall have been in the same calendar year.

Sec. 6.—Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional *credit for time* on the four years' course as follows: (*a*) To students having the A.B., B.S., or equivalent *degree* from reputable literary colleges, one year of time; (*b*) To graduates and students of colleges, of *homeopathic or eclectic* medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in materia medica and therapeutics; (*c*) To graduates of reputable colleges of *dentistry, pharmacy,* and *veterinary* medicine, one year of time.

Sec. 7.—A college not giving the whole four courses of the medical curriculum, and not graduating students, but otherwise eligible, may be admitted to membership.

Further information may be had of the Secretary, Dr. W. S. Hall, Berwyn, Chicago.

THE SOUTHERN MEDICAL COLLEGE ASSOCIATION.

The following extracts from the Constitution show a portion of the regulations controlling matriculants:

Art. IV. Sec. 3. He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate from some legally constituted high school, general superintendent of state education, or superintendent of some county board of public education, attesting that he has been regularly examined and is possessed of at least the educational attainments required of first grade teachers of public schools or a certificate that he has passed the entrance examination to a university; and a student may be given one month, from the date of his admission, to submit his certificate of qualification.

A candidate for graduation, among other provisions, "must have attended, in a regular and reputable medical college, four full courses of lectures, of not less than six months (26 weeks) each, in four separate years, which is construed to mean, that no two courses shall either commence or close in the same calendar year—that is, between the 1st of January and the ensuing 31st of December." (Art. VI, Sec. 2.)

The Secretary is Dr. G. C. Savage, Nashville, Tenn.

AMERICAN INSTITUTE OF HOMEOPATHY.

The minimum requirements for entrance into the freshman class of all homeopathic medical colleges, as adopted in 1901, are, with abbreviation, as follows:

1. English Composition. Exercise on assigned theme, not less than 200 words. Exercise in reading. Exercise in correction of ungrammatical sentences.

2. Mathematics. Arithmetical exercises in (a) vulgar fractions; (b) decimals; (c) percentage; (d) proportion; (e) square and cube root; (f) weights and measures; (g) decimal system. Mensuration. (a) Definition of terms; (b) exercises under the more fundamental rules.

3. Geography (general facts about North America).

4. History. General, with particular reference to human progress in art, science and letters. (The examination to avoid exact dates and minor details.)

5. Latin Language. (a) Grammar; (b) four books of Cæsar, or its equivalent.

The colleges recognized as in good standing by this organization are: [illegible] College of the Pacific; Denver Homeopathi[illegible]ahnemann Medical College, Chicago; Chicago [illegible] College; Hering Medical College; Homeopathic Medical Department of the State University of Iowa; Southwestern Homeopathic College; Kansas City Hahnemann Medical College; Southern Homeopathic Medical College; Boston University School of Medicine; Homeopathic Medical College of University of Michigan; College of Homeopathic Medicine and Surgery of University of Minnesota; Homeopathic Medical College of Missouri; New York Homeopathic Medical College; New York Medical College; Cleveland Homeopathic Medical College; Pulte Medical College; Hahnemann Medical College of Philadelphia.

CANADA.

The Dominion of Canada, with a population of 5,335,055, distributed through seven provinces and the Northwest territories, an area which reaches from the Atlantic to the Pacific, contains only 12 medical colleges. Of these, 5 are situated in Ontario, 4 in the province of Quebec, 2 in Nova Scotia, and one in Manitoba. One of the five colleges in Ontario is merely a teaching body; it does not confer degrees, since it is not in

affiliation with any university. The distinction between university and college in Canada is definite, namely, the latter is a teaching body only and has no right to grant a degree. Most of these colleges are mentioned below.

Toronto, Ontario.

UNIVERSITY OF TORONTO, MEDICAL FACULTY.—All the lectures and *demonstrations are given in the laboratories* and lecture rooms of the University; more than two-thirds of the instruction in the 3d and 4th years are given in the wards and in the pathological and *clinical laboratories.* A 5th year is now demanded by the Ontario Medical Council, for which provision will be made. Clinical instruction is given in the Toronto General Hospital. Mercer Eye and Ear Infirmary, Burnside Lying-in Hospital, Hospital for Sick Children, and St. Michael's Hospital. Before commencing students must satisfy, as to qualifications, the College of Physicians and Surgeons of Ontario (Provincial Board). Fees are: Registration (payable once), $5; each of the first four years, $100; fifth year, $50; for the degree of M.B., and M.D., each $20. Number of students registered last session, 405; graduates, 48. The sixteenth session, since the re-establishment of the Medical Faculty of the University, will commence October 1.

TRINITY MEDICAL COLLEGE.—This college is in affiliation with Trinity University, the University of Toronto, Queen's University, and the University of Manitoba. It is situated in Toronto. Toronto General Hospital, Hospital for Sick Children, St. *Michael's Hospital,* Burnside Lying-in Hospital, and the Eye and Ear Hospital are open to the students for clinical instruction. The entering candidate must pass the examination required by the Provincial College of Physicians and *Surgeons. The fee for each* session of eight months is $100, exclusive of fees for examinations and hospitals. Matriculates during last session were 147; graduates, 29. The thirty-second "consecutive winter session" will begin September 25, and continue for eight months.

ONTARIO MEDICAL COLLEGE FOR WOMEN.—This college is located Toronto, and is not empowered to grant degrees in Medicine, but it qualifies students fully to take the examinations in any university. The college requires no certificate of matriculation examination, but will accept that of the university selected by the student. The fee for each year is $100, exclusive of all hospital and university fees. The number of undergraduates, 1901-2, was 339; graduates, 52. The nineteenth session will open September 16 and continue for eight months.

London, Ontario.

MEDICAL DEPARTMENT OF THE WESTERN UNIVERSITY.—This college makes use of Victoria Hospital for its clinical work. The fee each year is $90, and $25 for graduation. The requirements for matriculation are those demanded by the College of Physicians and Surgeons of Ontario, and the full course is one of five years. The matriculates of last session were 84; graduates, 15. The twenty-first session opens Sept. 9, 1902, and ends May 7, 1903.

Montreal, Quebec.

UNIVERSITY OF BISHOP'S COLLEGE, FACULTY OF MEDICINE.—The course leading to the degree of C.M., M.D., extends over four years of nine months each. The annual fees are $100, which include all practical classes and material for the same. Students must, on en*tering the study of medicine,* pass the college matriculation examination, or if the license for the Province of Quebec is desired, that of the College of Physicians and Surgeons of that province. Special *facilities are offered for the practical teaching of obstetrics, and* undergraduates are obliged to take entire charge of several accouchments before being allowed to take the final examination. Other clinical facilities are offered in the Montreal General Hospital, the Royal Victoria Hospital, the Western Hospital, the Hotel Dieu, and the Women's Hospital. During the last session the students numbered 76; graduates, 7. The session for 1902-3 will open October 1.

MCGILL UNIVERSITY, FACULTY OF MEDICINE.—This college has a course of four years of nine months each. The total fees for the course are $500. Clinical instruction is given in the Montreal General Hospital, Royal Victoria Hospital, and Montreal Maternity Hospital. Students, except university graduates in arts, must pass the preliminary examination equivalent to that required by the Provincial College of Physicians and Surgeons. Last year's matriculates numbered 473; graduates, 96. The seventy-first session will *commence September* 23.

Quebec, P. Q.

UNIVERSITE LAVAL, FACULTE DE MEDECINE.—The course consists of four years. The fees for the entire course are $220 and $300, *according to preliminary qualifications. The matriculates during* last session were 97; graduates, 19.

Halifax, Nova Scotia.

FACULTY OF MEDICINE OF DALHOUSE UNIVERSITY.—The course consists of four years of eight months each, and leads to the final M.D. and C.M. examination. Prospective students must pass the preliminary examination of the Provincial Medical Board, a university examination or a recognized equivalent. During last session there were 88 students, of which 21 belonged to the graduating class.

NOTES.

In the Table indicating homes of students, those marked foreign include Canadians. This will explain the number in the "foreign" column, in certain colleges located near the

border. Some colleges were unable or failed to enumerate students by states. These do not appear in this table.

There are a number of medical schools not given here because they do not grant degrees. Many of them conduct only the first two years of the medical course.

In the Canadian schools given on page 572 no detailed mention was made of the following colleges, from which catalogs or other data were not received: Faculty of Medicine, Queen's University, Kingston, Ont.; Manitoba Medical College, affiliated with the University of Manitoba (the course of the latter is four years of eight months each); Ecole de Medecine et du Chirurgie. (This college is the Montreal branch of the Medical Faculty of the Universite-Laval in Quebec. It is a French school and was incorporated in 1845. Its students in all classes now number from 280 to 300 each year); and Halifax Medical College. The last mentioned college supplies no "preliminary examiners"; students are referred for examination to the Registrar of the Provincial Medical Board. The course consists of four years of eight months each. The fees for the full course are $300, and $30 for graduation.

The changes in colleges this year are the consolidation of Denver College of Medicine and Gross Medical College, the suspension of Northwestern University Woman's Medical College, Chicago, and Cincinnati College of Medicine and Surgery and the establishment of Oakland College of Medicine and Surgery, Oklahoma City Medical College, Department of Medicine of Temple College, Philadelphia, and the Physio-Medical College of Texas. Some minor schools, which hardly could be said to exist before, have gone out of existence.

The only three-year medical school remaining is the North Carolina Medical College. The restriction of the state boards of registration are leaving few states available for practice to the graduates of this school. Sewanee Medical College, Tenn., was a three-year school but begins a four-year system this year.

A Note on Teaching the History of Medicine.—William Osler observes, in the *British Medical Journal,* that in the everyday work of the wards, and of the out-patient department, the student may be helped to get into the habit of looking at a subject from the historical standpoint. In his out-patient class this is made a special feature of the teaching. A case of exophthalmic goiter comes in—the question at once is put: Who was Graves? Who was Parry? Who was Basedow? Of course the student does not know; he is told to bring, on another day, the original article, and he is given five to ten minutes in which to read a brief historical note. Osler takes from the class-book at random the titles of some subjects which have been presented this session, very often to the edification of the teachers as much as the students: Sydenham's description of chorea, Valsalva's method of treating aneurism, Tufnell's method of treating aneurism, the history of our knowledge of lead poisoning, Abram Colles and his law, Dr. King's safety valve action of the tricuspid valve, Bright's original description of the disease which bears his name, Glisson's original description of rickets, Blaud and his pill, the history of hemophilia in America, the history of diabetes. Once a week he meets his clinical clerks in an informal conference on the events of the week. For half an hour he gives a short talk on one of the "Masters of Medicine," in which, as far as possible, the original editions of the works are shown. In the present crowded state of the curriculum it does not seem desirable to add the "History of Medicine" as a compulsory subject. An *attractive course will catch the good men and do them good,* but much more valuable is it to train insensibly *the mind of* the student into the habit of looking at things from the historical standpoint, which can be done by individual teachers.—From the *St. Louis Med. Review.*

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street :: :: Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, SEPTEMBER 6, 1902.

THE MEDICAL COLLEGE STATISTICS FOR 1902.

One hundred and fifty-six medical colleges, with 6,776 instructors, enrolled 27,501 students and graduated 5,002 students in the school year 1901-2. In the year previous. 1900-1, 156 colleges, with 5,958 teachers, enrolled 26,417 students and graduated 5,444. Twenty years ago there were 89 medical schools with 14,934 students and 4,115 graduates. The increase in the number of schools and students is far in advance of the increase in the number of graduates. The graduates twenty years ago were 4,115: in 1900, 5,314; in 1901, 5,444, and in 1902, 5,000. The attendance in twenty years has therefore increased nearly 200 per cent. and the number of graduates has increased less than 25 per cent. The decrease in the number of graduates in the last year is assigned to the increased length of course of study and increased requirements by state boards. It is considered by many a temporary decrease and one that will be changed to an increase as soon as the temporary check is overcome. The decrease in graduates is classified thus: There were 4,879 graduates from the regular colleges in 1901; 387 from the homeopathic: 148 from the eclectic, and 30 from the physio-medical and nondescript; total, 5,444. In 1902, 4,498 graduated from regular schools; 336 from the homeopathic; 138 from the eclectic, and 27 from the others; a decrease in every class. The increase in students is classified thus: There were 23,846 students registered at the regular colleges during the year ending July 1, 1901; 1,683 at the homeopathic; 664 at the eclectic, and 224 at the physio-medical and nondescript; a total of 26,417. During the year ending July 1, 1902, 24,878 students registered at the regular colleges; 1,617 at the homeopathic; 765 at the eclectic, and 241 at the physio-medical and nondescript; total, 27,501. This is an increase among all but the homeopathic schools. In the year the regular schools increased in enrolment 1,032 and decreased in number of graduates 381. The homeopaths lost in enrolment 66 and in graduates 51; the eclectics gained in enrolment 99 and lost 10 in graduates; all other schools gained 17 in enrolment and lost 3 in graduates.

THE MODERN UNIVERSITY MEDICAL SCHOOL.

In another part of this issue will be found a most excellent, thoughtful and practical paper on the modern university, with special reference to the part the medical department should play in the university as a whole and in its relations to the other special departments. Whatever the ideal university may be, and there is room for some difference of opinion in regard to this, the author of the paper has fairly stated his ideas on the status of the medical school in the university and the function of the university body as a whole in its relations to the medical department. We wish to speak, however, about two features: the author's views in regard to the facilities for medical education and the innovation of the continuous course.

THE JOURNAL has long maintained that it is quality and not quantity that is demanded in the American medical profession, and that our systems of medical education have heretofore worked directly against this desideratum. We have multiplied medical colleges, reduced expenses and in every way sought to facilitate entrance into the profession. If the university medical school is to continue this policy it seems to us that its real usefulness to the profession and the public will be to that extent reduced. Nevertheless, this seems to be in a measure one of the ideas advanced by the author of the paper. He offers his ideal of requirements that should be demanded for admission, a high-school course and two years of college, and while admitting the advantages of a full collegiate course, holds that it would be unfortunate if all the high grade medical schools should adopt such a requirement.

None of us ever exceed our ideals in practice, unless, indeed, they are so low that circumstances force us to do so, and such a condition of affairs is not to be here considered. If we lower our ideals we lower conduct still more, and this is as true as regards medical education as anything else. The author admits that provisions must be made for exceptions in which his standard is not to be required, and it will be very easy in practice to make such exceptions prove to be the rule. There would be every temptation to such a course. If a man has a real vocation to medicine and the needed virile energy, he will get his medical education if he has to get a college degree first. It should not, in our opinion, be the aim in medical education to in any way lower the standard or to render the entrance into the profession less difficult than is demanded by a course that will be equal to that given in any part of the world. Let the high-school course and the two years of college be the minimum and not the ideal requirement for admission.

We wish, however, to protest against another view advanced. The author speaks of the continuous course as beyond question one of the features of the future university school of medicine, which may be true, but the arguments advanced for it do not strike us favorably. It may be more profitable to keep open house for medical aspirants all the year round, but this is not the highest sort of argument for the course. In several of the state medical practice laws it is particularly specified that the three or four medical courses must be in separate years, and similar provisions are included in other states in the regulations which the registration boards are authorized to make. This has been rendered necessary, or at least so considered, in the past, and very likely will be still so considered in the future. We do not therefore fully appreciate the force of the plea for the continuous course that it should be adopted because it will enable the ambitious, progressive student to shorten the period between his matriculation and graduation, or that this ought to be made possible. The specially able student ought, in a university, to be able to profitably spend four years' study time, even if he has to exceed the minimum requirements of a pass examination by so doing, and we believe it will be more profitable for him and beneficial to the profession generally to make it compulsory so to do. The continuous course should not mean in any sense a short cut into the medical profession. Neither do we think that it is so intended by the author.

There is very much in Dr. Dodson's article that we can cordially approve, and its very excellence as a whole makes it appear the more necessary to call attention to this point. In the past, American medicine has suffered before the world because, while its focal brightnesses have been conspicuous, its average illumination has been considered low. We should therefore in the work, in which we all are so earnestly concerned, of elevating its standing, be most jealously critical of any and every tendency, however recondite or insignificant it may appear, that may defeat our object.

THE EXTRAMURAL CLINIC.

The problem of providing a sufficient amount of clinical material for the adequate instruction of students is coming to be a serious one. The exhibition of patients, medical or surgical, in an arena clinic, before large classes, can no longer be deemed an adequate means of training as a preparation for practical life. It would perhaps have been better if the term "clinic" had never been applied to such an exercise. As ordinarily conducted it might be more properly termed an illustrated didactic lecture. The word clinic, signifying as it does, etymologically, the bedside, ought to indicate an exercise in which the students singly, or in small groups, are brought actually to the bedside of the patient so that each individual is allowed to examine by sight, hearing and touch the phenomena presented. Only by such methods can the eye, the ear, the tactile and other senses be properly educated. The provision of cases in sufficient numbers to teach in this way large classes of students, means a very large number of hospital beds and dispensary patients. We know of no medical school which possesses these facilities to anything like the degree necessary. The maintenance of hospitals, under the absolute control of the college, is enormously expensive—far and away the most costly item in the conduct of the institution. On the other hand, there are, in every large city, many hospitals to which the admission of students, under suitable restrictions, would inevitably result in the more thorough and careful examination of the patients and the stimulation of the attending staff to better work. It is a trite but true observation that only the very rich and the very poor receive the best medical attention—the rich because they are able to pay well for it, and the poor because they are largely to be found in teaching hospitals under the care of the most able and painstaking diagnosticians—the medical teachers.

Here, then, are physicians on the staff of unattached hospitals who are willing and anxious to teach, students greatly in need of clinical material and instruction and patients who will be benefited in every way by being made the subjects of such examination and demonstration. How can these several groups be mutually helpful to each other? The extramural clinic, so long in vogue in Edinburgh and other foreign schools, seems to offer a solution, and is being utilized in some of our American colleges. Clinics are offered at these outlying hospitals by members of the staff, to which the students of a neighboring school or schools are admitted, the physicians giving such courses becoming extramural members of the faculty of the college. Certain provisions are necessary to the perfect success of the plan. The elective system greatly facilitates its successful operation, for such work must be made elective on the course for the degree, credit being allowed in proportion to the amount and character of the work. The exercises in each hospital and for each group of students must be so arranged that there is the least possible loss of time in going back and forth. This is best accomplished by arranging for exercises at one place to occupy a half day. When so arranged experience has shown that students will cheerfully go several miles to attend them. The classes must be small, seldom exceeding eight or ten, for the chief inducement to the student is the opportunity afforded him to come into immediate contact with the patients. The teachers must be carefully selected with regard to their ability and faithfulness; never should an extramural appointment be made simply because the appointee commands a large amount of material.

Great care must be exercised in the careful handling and the courteous treatment of the patients, and when this is done they not only do not resent, but eagerly welcome the opportunity to be presented to the class. There are few exceptions to this rule. It is rarely necessary or best, for either patients or students, that the latter be taken into the large wards of a hospital. All of the advantages of "walking the wards" with the clinician may be much better secured by having patients brought to an examining room—one, two or three at a time—to be studied there, away from the noise and distractions of the large ward.

Numerous hospitals aggregating thousands of beds are within easy access of the medical schools. Only the persistent, tactful education of the public, and especially of the managing boards, is necessary to open their doors for clinical instruction, which, with ment, must inevitably result in the benefit of all concerned. It is safe to predict a large field of usefulness for the extramural clinic.

MEDICAL HISTORY.

Over a year ago[1] we directed attention to the need of more general study of the historical side of medicine. In view of the importance of the subject and the almost universal interest being awakened in it at present, it will not be amiss to refer to it again, and to mention some recent additions to medical history in America. In "The Relation of Yale to Medicine," delivered at the two hundredth anniversary of the founding of the college,[2] Prof. Wm. H. Welch of Baltimore has added another article to the list of those relating to American medical history. In this paper he writes in his usual interesting manner about the founding of Yale Medical Department and the men who have been active in advancing its interests. He emphasizes the value of a good practical knowledge of chemistry, physics and general biology in the preliminary training of prospective medical students, and gives to Yale the credit of first clearly recognizing and supplying this want in the Sheffield Scientific School.

The history of American medicine has received many valuable contributions through the activities of the Johns Hopkins Historical Club. These have been published in the *Johns Hopkins Hospital Bulletin* and have served to familiarize American physicians with the work of men concerning whom they had previously known but little. A recent article by J. G. Mumford[3] has added a biographical sketch of Dr. Jacob Bigelow, which is worthy of a place among the previous ones. Mumford says that the Massachusetts Institute of Technology, with its splendid curriculum, its strong staff and its host of highly trained and successful graduates, stands to-day a monument, in part at least, to the energies of Jacob Bigelow. In an article on "The Work of Jenner and His Most Faithful Disciple, Waterhouse." Wm. M. Welch of Philadelphia has introduced, for the first time to a large part of the profession, the man through whose efforts vaccination was introduced into almost every city and town in the country. I. N. Danforth[4] furnished our readers a valuable, although necessarily incomplete history of Samuel Fuller, "the earliest practitioner of medicine in Massachusetts."

These recent writings on the history of American medicine and medical men are an indication of the interest being taken in the history of the medical affairs of our own country, and should serve to stimulate similar efforts by others who are in positions to contribute anything of value and interest.

Instruction in medical history should be given in every medical school. Provision for this has been made in several, but it is far from general. Such instruction by a well-informed lecturer could certainly be made very popular among students, and would have the effect of enlarging the interests and elevating the ideas of many students regarding their chosen profession.

In the Italian universities, medical history seems to have occupied a better position than elsewhere, regular lectures upon this subject being given in most of the Italian schools. The editor of the *British Medical Journal*[5] made the statement that there was no professor of medical history in England, Germany or Holland. In a later issue[6] it appears that lectures on this subject are given in the universities of Vienna, Berlin and Würzburg. Formerly such lectures were provided by many of the German universities, but for some reason they have been largely discontinued. E. Braatz[7] urges the German universities to resume instruction in medical history. The agitation of the subject in England and Germany may be expected to lead to more general interest, and with it medical history will take its proper place in the medical course.

In America our own medical history is receiving the attention of some of our most talented men, and it is to be hoped that every medical school will soon have a professor of medical history who shall be sufficiently remunerated for his work so that he may be a man with special ability and preparation for the place.

DISINFECTION OF THE URINE IN TYPHOID FEVER.

If a physician were to neglect disinfection by some simple, recognized method of the stools in typhoid fever, he would be held blamable, and justly so. If he were to omit cautioning the consumptive in regard to the dangerously infectious character of the sputum, he would be regarded as careless and negligent. Again, if the physician were to permit his scarlet fever patients to run about in the neighborhood before desquamation is completed, it would spread consternation through the community and the general condemnation of such action would not be slow in making itself effectively heard.

Numerous other instances could be mentioned of equally glaring sins of omission and commission in the preventive treatment of infectious diseases against which the general professional conscience would protest. How is it in the case of the urine in typhoid fever? It is demonstrated beyond doubt that in a considerable percentage of the patients suffering with typhoid fever, typhoid bacilli occur in the urine in large quantities, frequently so numerously that the urine is rendered turbid on that account alone. It is furthermore known that typhoid bacilli may persist in the urine for months and even years after an attack of typhoid fever, such persons being in reality perambulating disseminators of bacilli, which are deposited wherever urine falls. In this way, unless precautions are taken, the cause of typhoid fever may be perpetuated locally and new foci of disease started as the bacillophorous urine finds its

way into the sources of water supply. With the springing up of brisk endemics of typhoid here and there the question arises, are physicians using proper precautions in regard to the urine of their typhoid patients? Has the proper care of the urine become a matter of definite routine as is the case with the stools? Probably much more ought to be done than is being done. Certainly a convalescent typhoid patient should not be allowed to leave the hospital or be discharged from supervision before the condition of the urine as to the absence or presence of typhoid bacilli has been established. This would require a bacteriological examination of the urine, at least in many cases, and this the vast majority of private practitioners are unable to do as thoroughly as modern sanitary ideas require. In the case of hospitals, however, such examination ought to be a matter of routine. We are in need of further reports concerning the presence and persistence of typhoid bacilli in urine after attacks of typhoid fever. Careful observations should be made with the view to the establishment of easily practicable methods by means of which the practitioner can determine for himself the condition of the urine of his typhoid patients. In the meantime, it is our plain duty to do all in our power to prevent the spread of typhoid fever by the urine. Much may be done by the systematic use of reliable urinary disinfectants, such as urotropin, which should be administered for a reasonable time to every typhoid convalescent. Patients should be informed of the fact that their urine may be dangerous. No doubt some of them would feel the responsibility thus placed on them and exercise a certain degree of care.

This is another striking example of the direct and real value of bacteriological laboratory methods applied to practical medicine. As the matter now stands it is quite clear that practitioners of medicine, in order to do their full duty in this matter of typhoid fever, must possess or control sufficient bacteriologic skill and apparatus to determine whether or not the urine of their typhoid patients is free from typhoid bacilli before returning to their usual modes of life.

A TESTIMONY.

The *Hahnemannian Advocate,* a publication whose name indicates its character and aims, is disturbed by the statistics of medical education given in our last year's educational number. It says editorially:

> We have not the space to show the summaries from which the *per cent. of gain* made by the dominant school for the past ten years may be drawn, but the fact remains and must be faced. A study of these summaries reveals the fact that:
>
> 1. There are only five allopathic to one homeopathic college, although their alumni are more than ten to one.
> 2. Their teaching force outnumbers our own, because their laboratories are more extensive and better-equipped.
> 3. Their average attendance is about one hundred and ninety, while we have only seventy-five.
> 4. The similarity in the course of study during the first two years naturally leads the student to select that institution offering the most comprehensive laboratory facilities
> 5. The similarity in the course of instruction during the last two years naturally leads the student to stay where he is.
>
> We believe these five conclusions tell the whole story. There are too many homeopathic colleges for the present support, hence they are compelled to draw on private resources for the necessary means to carry on their work. Their laboratories are incomplete and clinical facilities inadequate. Only such students are drawn to their classes as have been impressed with superiority of homeopathic principles before they become medical students.

We do not often quote this contemporary, but the above testimony is perhaps of some interest on account of its source.

THE RETIREMENT OF GOVERNOR GAGE.

The country is to be congratulated on the failure of Governor Gage of California to receive a renomination by his party. His course in regard to the existence of plague in San Francisco, the ostrich policy he adopted and the measures he seems to have advocated for the suppression of the facts should each and all condemn him to retirement from public life at the present time. We do not know at this distance and at the present time what were all the factors in the contest, but may allow ourselves to legitimately infer that Governor Gage has not won all the popularity he anticipated from his zeal in suppressing facts that seemed to him against the commercial interests of the city of San Francisco. The fact, also, that the successful nominee, Dr. Geo. C. Pardee, is a physician is perhaps significant. So far as we have yet heard there is nothing in his record that would indicate that he would put himself in opposition to his profession and continue a policy that is full of danger not only to the state of California but of all regions in connection with it. Plague, properly managed, does not in these modern times seem to be such a general peril in civilized countries as in times past. If, however, its existence is wilfully ignored or due precautions are not employed, there is no telling when an outbreak of the disease may not occur, rivaling in severity those of the past. The existence of an Oriental population in California, herding by itself under the most unsanitary conditions in its cities and concealing rather than reporting infectious disease, renders the existence of such an infection as bubonic plague among them a very serious problem, demanding the most earnest attention on the part of all who have to do with the administration of state affairs. Whatever Governor Gage's merits may have been in other respects, he was wilfully and culpably lacking in his duty in this particular regard. This is not an unimportant matter; it is the one question of all others that has arisen in his administration, that concerns not only California but all the rest of the country. Any change would therefore be welcome as an end of what has been, and the nomination of a medical man in sympathy, as we trust, with the best element of his profession, is the strongest possible rebuke to the ostrich policy of the past.

PATENT INSIDES FOR MEDICAL JOURNALS.

Medical journals with "patent insides," like the daily papers that are published in country towns, are almost in sight. Two concerns in an eastern city announce that they are going to syndicate a group of medical journals which will pretty well cover the United States. They propose to employ medical writers who will contribute to the papers controlled by the syndicate. The matter thus produced is to be made into plates at headquarters and furnished to each of the journals once a month. They announce that they have employed translators and abstractors, and that they will occupy with their matter some twenty-four pages in each issue of each of the journals entering into the arrangement. There is to be no charge for this service, except that the syndicate managers are to have absolute control, without cost to them, of a certain number of advertising pages in each of the journals. Up to the present time the promoters of these schemes are not asking the journals to pay them in this way much over three times what their service would be worth when rated at the highest notch. The scheme is a bad one, because it will tend to stereotype medical literature and to crush original work in medicine, that is, in case it were generally adopted, which, of course, is not at all likely. Very few journals will agree to such a one-sided arrangement, and those that do will necessarily be marked by the profession as being almost moribund. But the most objectionable feature of the proposition lies in the fact that any journal accepting it thereby places a certain amount of its space for original matter and a certain number of its advertising pages under the control of laymen who have no interest in maintaining ethical standards, but whose chief aim will be to make money out of the scheme, even if in doing so they send out as original articles papers which are written chiefly for the purpose of benefiting some advertiser. The medical profession can certainly not be expected to take a kindly view of such a proposal, and it does not seem possible that success will come to it. It is certain that hereafter readers of medical journals will examine them critically in order to discover which ones may have been deluded.

Medical News.

Owing to the space taken by the educational matter in this issue, all regular departments are greatly reduced and some are omitted.

CALIFORNIA.

Maternity Ward.—Through the generosity of Mrs. Robert J. Burdette, the building of a maternity ward for the Pasadena Hospital is assured.

More Plague in San Francisco.—During August, 2 new cases of bubonic plague were reported in San Francisco, making a total for 1902 up to this date of 13, with 12 deaths.

Riverside Hospital Incorporated.—Articles of incorporation of the Riverside Hospital Association were filed, August 20. The company is capitalized at $25,000, of which $6275 has been subscribed.

Dr. Lane's Estate.—The value of the estate of the late Dr. Levi Cooper Lane, San Francisco, has been appraised at $301,108.56. His widow, who died August 9, has left the bulk of the estate to Cooper Medical College.

Lane Medical Lectures.—The seventh annual course of Lane medical lectures was held this week. The lecturer was Charles B. Ball, M.Ch. Ireland, F.R.C.S. England, and regius professor of surgery in the University of Dublin.

CONNECTICUT.

Personal.—Dr. Brownlee R. Ward, U. S. Navy, has resigned and will devote his attention to private practice in New Haven.

Cancer Doctor Restrained.—In the case of A. Stanley Maine of Hampton, charged with practicing medicine without a license, the defendant was bound over to the Superior Court under $200 bonds, Maine agreeing to suspend practice until the Superior Court renders its decision.

Deaths in the State.—During July, 1394 deaths occurred, 333 more than in June, 97 more than in July, 1901, and 55 above the average of July for the five preceding years. The annual death-rate per 1000 for the larger towns was 19.9, for the smaller towns, 14.5, and for the whole state, 18.5. The deaths from infectious diseases number 527, or 37.7 per cent. of the total mortality.

The Hubbard Deeds.—The New Haven Medical Association stands in a queer relation to the property of Dr. Stephen G. Hubbard, which consists of grounds and a dwelling valued at $50,000. Dr. Hubbard, on May 11, 1901, deeded the property to the trustees of the New Haven Medical Association on condition that the association erect within three years after his death a building for its uses to cost not less than $10,000, the plans for which are to be submitted to him. The association recorded the deed. It was then discovered that a deed of the same property had been previously recorded conveying the property to a niece of Dr. Hubbard. Dr. Hubbard reserved the life use of the estate in both deeds.

ILLINOIS.

Personal.—Dr. Henry V. Bailey, Pekin, sailed for Glasgow, August 23.

Epileptic Home Burned.—The Illinois Home for Epileptics at Arlington Heights was burned, August 30. Through the efforts of the resident physician the inmates were rescued without casualty.

Lincoln Asylum Changes.—Dr. John R. Barnett, assistant superintendent of the Illinois Asylum for Feeble-Minded Children, Lincoln, has resigned, and Dr. Charles B. Taylor, Elkhart, appointed in his stead.

Chicago.

Personal.—Dr. Nicholas Senn has returned from his mission to St. Petersburg and a long journey to the Orient.

The University of Chicago.—At the recent convocation, President William H. Harper reported that the medical department had been paid a gift of $50,000, and that the expenses of the department for the year had been less than the estimated amount.

Deaths During August.—There were 2330 deaths from all causes reported to the health department during August, 1902, or 161 more in number and 3.9 per cent. more in the annual rate per 1000 of population, compared with the figures of August, 1901. The annual death-rate per 1000 was 15.06. The report shows that 610 children under one year old, died: that 597 deaths were caused by acute intestinal diseases; 193 by typhoid fever; 177 by violence; 181 by consumption and 136 by heart diseases.

Medical Arrangements for Labor Day.—On the line of march on Monday last five emergency tents were located, with thirteen physicians and five nurses in attendance. Three of these nurses were from the Visiting Nurses' Association and two from the Frances Willard Hospital. Dr. S. W. Cox was in charge of the headquarters tent at Michigan avenue. The day was free of serious accidents and fewer than a score of persons were in need of treatment, most of those treated being slight cases of overheat.

Efforts at Suppression of Typhoid.—When the excessive incidence of typhoid first forced itself on the attention of the department and study showed the so-called "storm center" to be located in the ghetto district, efforts for suppression were concentrated in those areas. But the work the department was able to do served mainly to show how futile and inadequate were its resources. Food, chiefly fruit and vegetables, unfit for human consumption, was condemned and sprinkled with kerosene, but the department had no authority similarly to sprinkle with kerosene the 20 per cent. of dwellings found in these areas unfit for human habitation.

Excess of Typhoid Fever.—Of the excess typhoid fever deaths contributed nearly 70 per cent., the respective numbers being 83 last August and 193, or 110 more, in the month just ended. This is the greatest number of August typhoid deaths ever recorded in Chicago. The highest previous August typhoid deaths were 182, in 1891. Since then the August deaths have been 179, 76, 52, 59, 64, 42, 45, 62, 34 and 83 for the respective years 1892-1901. These figures are cited to show that the department has been fomenting no unwarranted scare in its utterances on the typhoid situation during the last three or four weeks. They show an increase of fully 57 per cent. in the typhoid mortality of August, 1902, over the average August typhoid of the previous ten years.

NEW YORK.

New Medical Building for Cornell.—The contractor announces that the new medical building for Cornell will be ready for occupancy at the opening of the fall term.

Telephone-Receiver Infection.—Dr. Bissell, city bacteriologist of Buffalo, is to make bacteriologic examinations of receivers of public telephones with the idea of planning some method whereby infection from this source may be averted.

Buffalo Personals.—Drs. Roswell Park and Blair have returned from Europe.——Dr. Arthur J. Patek, Milwaukee, was the guest for a few days of Dr. Julius Ullman.——Dr. Jane W. Carroll was recently appointed supreme medical examiner of the Ladies' Catholic Benevolent Association.

Physiologic Laboratory Building.—The University of Buffalo Medical Department is building an additional story for the physiologic laboratory, at a cost exceeding $5,000. When the laboratories have been completed a prominent Buffalonian will completely equip them, thus making this laboratory one of the most complete in the country.

Fumigation of School Books.—The health department of Buffalo has undertaken to fumigate the 250,000 books used in the public schools. The old books will be placed in large receptacles and fumigated thoroughly with formaldehyd. Health Commissioner Green believes that danger of infection from communicable diseases will be averted in this way.

OHIO.

Bequest to Hospital.—By the terms of the will of the late Mrs. Katherine Aultman, $100,000 is bequeathed to the Aultman Hospital, Canton.

Youngstown Hospital Opened.—The new City Hospital at Youngstown, which has accommodation for 139 patients, and was given to the city by Myron C. Wicks, has been formally opened.

Declines Merger.—The efforts of President Thwing to make the medical department of Ohio Wesleyan University a part of the Western Reserve Medical School have been without result, as the university refuses to sell at the present time.

Personal.—Dr. Thomas A. Burke, Cleveland, has returned after a long course of special study abroad.——Dr. Royce D. Fry, Cleveland, has returned from Europe.——Dr. Frederick D Barker, Dayton, has resigned from the medical department of the Ohio National Guard.

Found Guilty and Sentenced.—Dr. James H. Ferrell, Marion, who was found guilty of an attempt to commit an operation which contributed to the death of Miss Laura Hite of Wyandot County, some time ago, has been sentenced to the penitentiary for two years.

Did Not Substantiate Charges.—The society which caused the arrest of Dr. John L. Hoyer of Cleveland failed to substantiate its charges at the trial. The warrant charged that the physician failed to qualify under any section of the statute regulating the practice of medicine. He was accordingly acquitted.

Dr. Brand at Last Successful.—Health Officer Dr. Walter W. Brand of Toledo, who has been untiring in his efforts to secure for Toledo a contagious disease hospital, has at last succeeded. The mayor signed the ordin [illegible] the issue of $20,000 in city bonds for the [illegible] the hospital.

Faculty Changes.—At Ohio Medical University, Columbus, Dr. John H. J. Upham has resigned as professor of principles of surgery and clinical surgery, and Dr. James U. Barnhill, elected in his stead; Dr. William McPherson was elected professor of chemistry, vice Prof. E. T. Watson, resigned; Dr. Theodore W. Rankin has been made full professor of therapeutics and clinical medicine.

PENNSYLVANIA.

Typhoid in Pittsburg.—Fifteen new cases of typhoid fever were reported in Pittsburg, August 22.

Many Apply.—The White Haven Sanatorium for Consumptives is overwhelmed with requests for admission. There are many on the waiting list. President Flick believes that at a cost of $6,000,000 tuberculosis could be stamped out of Pennsylvania in 15 years.

Personal.—Dr. Lena A. Benjamin, Bradford, sailed August 23 on the *Kroonland* for Antwerp, en route for India, where she is to take charge of a hospital at Nellore in the Madras Presidency.——Dr. Harris R. Lecrone sailed for Europe, August 16. He will take a three months' post-graduate course in Vienna.

Philadelphia.

Deaths of the Week.—Within the week ended August 30 there were 417 deaths from all causes as compared with 379 deaths for the previous week.

Personal.—Dr. George E. de Schweinitz has returned from a European trip.——Dr. John A. Passmore is seriously ill at his home.——Dr. and Mrs. Francis Correa of Germantown recently returned.——Dr. J. William White has made a trip over the Swiss Alps this summer.

Typhoid Epidemic Feared.—There are some grounds for fear of an epidemic of typhoid fever. For the week ended August 30 92 new cases and 10 deaths were reported. Only 56 new cases occurred the preceding week. The cases are distributed throughout the city and are probably due to an impure water supply.

Hospital Endowments.—By the will of the late Mary E. Jackson $5000 each, for the endowment of free beds, is bequeathed to the Pennsylvania Hospital and to the Protestant Episcopal Hospital. A reversionary bequest of $6000 is made to the Protestant Episcopal City Mission, in trust for the Hospital for Diseases of the Lungs, the purpose being the endowment of a free bed.

GENERAL.

New Resident at Molokai.—Dr. W. J. Goodhue, at present the physician and surgeon to Eleele plantation, Kauai, has been appointed resident physician to the Leper Settlement, Molokai, by the Hawaii Board of Health.

Discuss Cholera Situation in Manila.—The Board of Health held a joint meeting with the local physicians in Manila, July 11, for the purpose of considering the cholera question and to adopt measures for preventing the spread of the disease.

To Revise Regulations.—Dr. Arthur H. Glennan, U. S. M.-H. Service, Havana, has been appointed a member of the board of officers who have been selected to revise the regulations of the new Public Health and Marine-Hospital Service, and has started for New York.

Dysentery and Dhobie Itch Disappearing.—Surgeon-General Forwood has received recent advices that dysentery, which heretofore has caused more sickness and deaths than any other disease among the troops in the Philippines, has practically disappeared. It has succumbed to the strenuous efforts of the medical department for its eradication. Strict sanitary measures have been enforced, including the boiling of all drinking water, and rules for bathing, and particularly the washing of hands before handling food. Another source of great satisfaction to the medical department is the eradication of a tropical skin disease commonly called "dhobie itch." This disease, while not fatal, was considered almost in the nature of a scourge among the troops in the islands.

Cholera Situation Unchanged.—All hope of staying the cholera epidemic in the Philippines has been abandoned until the typhoon season sets in. Only light rains have yet fallen, serving only to stir up the streams and diffuse the cholera germs, and Surgeon-General Forwood says that no material change for the better can be expected until the heavier storms begin. He lays much of the blame for the spread of the cholera and its great mortality to the incapability of the majority of the Filipino doctors. So long as these were under the direct supervision of American officers they rendered valuable assistance in staying the epidemic, but when left to their own devices, through the reductions of the American force in the islands, he says, they have failed to carry out instructions, ignored the simplest rules of sanitation, and in many instances done more harm than good. The trickery of the natives in concealing new cases has also assisted in the spread of the disease.

Smallpox.

CONNECTICUT: In July 40 cases were reported in 4 towns. Thompson had 29 cases, New Britain 9, and Stamford and Waterbury each one.

ILLINOIS: Springfield is the only city reporting a case of smallpox to the State Board of Health during last week; the patient came from Patoka, Indiana.——There were but nine cases of smallpox discovered in Chicago during August, and of these only two were residents; of the remainder, three were importations from Cleveland, one from Wisconsin, one from Indiana and one from the state outside Chicago. None had ever been vaccinated; there were no deaths from the disease, and at the close of the month there were only nine cases under treatment in the isolation hospital.

Maryland: Another case of smallpox is reported near Williamsport in the western part of the state. Several cases have previously existed in the suburbs of that town, which are still under quarantine and special treatment.

Pennsylvania: The town of Parryville, Carbon County, is suffering from an epidemic of smallpox; nearly one-tenth of the population of 500 is affected by the disease. A strict quarantine has been established.

Canada: There are now but four cases in the Montreal Hospital, and the disease will be wiped out in a very short time.

England: The Metropolitan Hospitals, London, now contain only 305 cases of smallpox against numbers decreasing from 1515 to 369 on the 14 preceding Saturdays; 44 new cases were admitted in the last week against 51, 48, 23 in the three preceding weeks. During the second quarter of the year the number of fatal cases amounted to 507, against 35, 193 and 734 in the three preceding quarters, and an average of 11 in the second quarters of the ten preceding years. During the quarter 3215 cases were admitted to hospital against 286, 1491 and 4873 in the three preceding quarters.——The medical officer of health for Swansea has reported to the sanitary committee that smallpox, which has been prevalent at that port for some months, has assumed serious proportions, and is now in epidemic form.

Barbadoes: Smallpox has again made its appearance in this island, there being now 15 cases strictly isolated at the quarantine station, located on Pelican Island, separate from the mainland. The prevailing opinion among the physicians is that the disease is under control and will not become epidemic. No deaths have been reported by the Board of Health.

CANADA.

Montreal Death Roll.—The mortality statistics for the past week in Montreal show a total of 123 deaths. The principal causes of death were: Phthisis and other chest diseases, 29; infantile debility, 49; croup, 1; typhoid fever, 2; measles, 2.

Appointed Autopsist for Montreal District.—Dr. C. A. Dugas, who for some years was assistant to the late Dr. Wyatt Johnston, the autopsist for the district of Montreal, has been appointed by the Attorney General of the province of Quebec to succeed Dr. Johnston. He will have as his coadjutor Dr. D. D. MacTaggert.

Heavy Infant Mortality in Toronto During August.—The returns from the Toronto cemeteries during the month of August show a total of 246 interments, or 15 more than for the month of July. The total deaths from contagious diseases were three, all diphtheria. There were 111 children under five years of age interred, and 11 adults over 82 years, one over 90 and one 92 years of age.

Enforcing Montreal's Vaccination By-Law.—A case of some importance has been decided by Recorder Porier in regard to the right of the city of Montreal to enforce the by-law calling upon the employers of labor to compel employes to be vaccinated. The action was taken by the medical health officer to compel the vaccination of an employe of the Dominion Cotton Company. The recorder imposed a fine of $5 on the company.

FOREIGN.

Merida Hospital.—The contract for the construction of the Merida, Yucatan, hospital, for the sum of $900,000, has been given to Mexican contractors.

Esmarch's Birthplace.—The house in which Esmarch was born at Tönning, in Schleswig-Holstein, has been marked with a tablet by the local authorities.

Forged Diplomas at Barcelona.—The faculty at Barcelona have discovered that several persons are in possession of forged diplomas conferring degrees in medicine or law. All the diplomas issued in the last twenty-five years are now being revised and verified.

Recrudescence of Plague in Sydney.—On July 11 a rat infected with plague was discovered in Sydney, and a week later another rat dead from plague was found. It is reported that rats are dying in the district, and thorough inspection and cleansing of the affected locality have been made.

Prophylaxis Against Mosquitoes in France.—The French Conseil d'Hygiène recommends the usual measures against allowing stagnant water to accumulate, etc., and adds that fish should be kept in all public fountains, etc., and that a drop of tincture of iodin or of a 1 per cent. solution of guaiacol should be applied to every mosquito bite.

Statistics from the German Universities.—The number of medical students in Germany was 8141 in 1897, while at present it is only 6749, *a decline of nearly 17 per cent.* in the last five years. Berlin and Munich have about the same number of medical students as in previous years, 1018 and 1046 respectively, and the attendance at Rostock, Kiel and Heidelberg has increased. The decline is most apparent at Würzburg, Leipsic, Greifswald and Breslau.

The Prizes Offered by the Brazilian Academy of Medicine.—The Academy offers a gold medal and diploma for the best and second best works received during the academic year on the following subjects: Influence of malaria as a determining factor in aortic heart affections; fevers at Rio de Janeiro; clinical study of intestinal sutures; treatment of umbilical hernia; carcinoma of uterus; puerperal eclampsia; rôle of vegetable oxidases in therapeutics, and study of the mineral waters of Brazil, besides a few topics of merely local interest.

Golden Jubilees of German Physicians.—Our German exchanges this week bring a list of eight physicians whose friends have recently celebrated the fiftieth anniversary of their entrance upon their professional career. Among them is Dr. C. Schweigger of Berlin, who was decorated with the order of the Red Eagle on the occasion. L. W. Liersch of Kottbus was another. His name is well known by his works on ophthalmology and the history of medicine. Aufrecht of Frankfort a. O. closes the list. Several are "privy sanitary councillors" and one retired from active life two years ago.

Correspondence.

Gastroptosia not Gastroptosis.

New York, Aug. 19, 1902.

To the Editor:—In my letter which appeared in your issue for August 16 I noticed an error which may be either the printer's or my own slip of pen in manuscript. It reads "*epi* means on, upon or touching," while I wish to say "*peri* means on, upon or touching."

Being prepared to meet opposition—since it is generally believed that "*peri*" means around only—I ask you to insert this correction.

I know some of the Greek dictionaries are not explicit enough in regard to this word, and therefore allow me to say that not only in Greek spoken at present, but also in classical writers peri may distinctly mean "*upon.*" Περὶ, λίθον τεσέιν (Aristophanes, Acharnians v. 1180). Περὶ νῆσον ἀλώμενοι (Odyssey 4, 368).

A. Rose.

[Dr. Rose's original letter shows that he was responsible for the error.—Ed.]

The Relief of Itching in Ivy Poisoning.

Attleboro Falls, Mass., Aug. 28, 1902.

To the Editor:—Another remedy for the condition mentioned on page 441 of The Journal of August 23, itching of ivy poisoning, is to apply cloths rung out in a solution of grindelia robusta or eucalyptol and hot water, 1 to 10.

Respectfully, Willis L. Hale.

Book Notices.

American Edition of Nothnagel's Encyclopedia. Diphtheria. —By Wm. P. Northrup, M.D., of New York. Measles, Scarlet Fever, and German Measles.—By Professor Dr. Th. von Jurgensen, Professor of Medicine in the University of Tubingen. Edited, with Additions, by William P. Northrup, M.D., Professor of Pediatrics in the University and Bellevue Medical College, New York. Handsome Octavo, 672 Pages, Illustrated, Including 24 Full-page Plates, 3 of Them in Colors. Cloth, $5.00 net; Half Morocco, $6.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This latest volume in the Nothnagel's series is devoted to the most common of the diseases met by the general practitioner, namely, diphtheria, measles, scarlet fever and German measles. The monograph on diphtheria, consisting of nearly 200 pages, is not from the German edition, but is written especially for this volume by Dr. W. P. Northrup, of New York. The author is to be congratulated on the exhaustive and practical manner in which he presents the subject. The remarkably favorable results from the use of antitoxin is shown by statistics which are presented in a convincing manner and whose reliability can not be denied. The plates illustrating the introduction and removal of the intubation tube show in a most practical and helpful manner the various steps in this often necessary, but to the novice, dreaded operative procedure. As the author says, every general practitioner, and especially one who lives far from cities, should be familiar with the process of intubation, and the text and illustrations in this monograph will make the operation one of comparative ease. The bibliography at the end of the article is practically a complete one. The articles on measles, scarlet fever and German measles by Von Jürgensen are exhaustive treatises on these diseases, with numerous additions by the American editor. The so-called "fourth disease" is not mentioned by the German author but the American editor discusses the question briefly and apparently does not believe that the existence of the disease as an entity has been proven. All that has been said in regard to former volumes in this series should be repeated here, and as volume by volume is added to this English translation, the enterprise of the publishers is more and more appreciated.

A Manual of Otology. By Gorham Bacon, A.M., M.D., Professor of Otology in Cornell University Medical College, New York. With an Introductory Chapter by Clarence J. Blake, M.D., Professor of Otology in Harvard Medical School, Boston. New (3d) Edition. In One Handsome 12mo. Volume of 437 Pages, with 120 Engravings and 7 Plates in Colors and Monochrome. Cloth. Price, $2.25 net. Philadelphia and New York: Lea Brothers & Co.

This condensation of the general principles of otology is designed as a work of easy reference for the student, and the book has been considerably enlarged and a number of original illustrations added and some new topics introduced, including lumbar puncture and the significance of leucocytosis in oral diseases.

The Roller Bandage. By William Barton Hopkins, M.D., Surgeon to Pennsylvania Hospital. With Illustrations. Fifth Edition, Revised. Cloth. Pp. 162. Price, $1.50. Philadelphia: J. B. Lippincott Co. 1902.

While this little volume, which here appears in its fifth edition, is called the "Roller Bandage," it is in fact a treatise of bandaging in covering the general principles. It is nicely illustrated with completely new illustrations.

State Boards of Registration.

Report of Examination in Indiana.—Dr. W. T. Gott, secretary of the Indiana State Board of Medical Registration and Examination, reports the examination held at Indianapolis. July 8 to 10, as follows: Number of subjects, 18; number of questions, 130; percentage required to pass, 75. The examination was written. Number examined, 73; passed, 67; failed, 6.

William Foster, Jr., M.D., Princeton, N. J., to Miss Helen Dunham Stewart of Warren, Ohio, September 3.

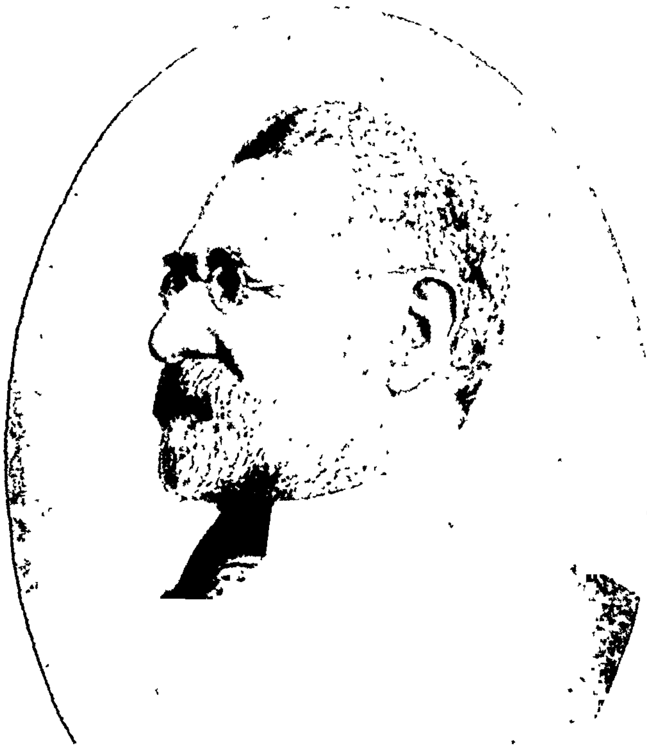
Deaths and Obituaries.

Aaron Friedenwald, M.D.

Dr. Aaron Friedenwald died at Baltimore, August 26, from the effects of an operation undertaken for the relief of cancer of the stomach, aged 65. He had suffered from gastric symptoms for some months past. Early in May he went to Europe, and, August 1, the diagnosis of carcinoma was made. Dr. Friedenwald at once returned to Baltimore. August 20 an operation revealed such extensive involvement of the structures about the pylorus as to make only a gastro-enterostomy possible. The operation was concluded with satisfaction and hopes were entertained that he would recover from it. But vomiting set in, with uncontrollable hiccough, and he died six days later.

Dr. Friedenwald held a high rank in the medical profession of this country. He was born in Baltimore, Dec. 20, 1836. He obtained his medical degree at the University of Maryland in 1860, and was a student in the office of Prof. Nathan R. Smith. He then spent two years in Germany preparing himself under Von Graefe and other great specialists in Berlin, Vienna, Prague and Paris for the practice of his chosen specialty. Returning to Baltimore he entered upon practice as an ophthalmologist and otologist, which he continued up to the time of his last illness. In 1873 he became a member of the faculty of the College of Physicians and Surgeons, and was always one of its most steadfast supporters. To him in very great degree the college owed its success. He also held the position of treasurer and chairman of the executive committee of the institution for many years.

Dr. Friedenwald was a public-spirited physician and took an active part in professional and civic work. He was a member of the American Medical Association; a member, and in 1889-1890, president of the Medical and Chirurgical Faculty of Maryland; first president of the Maryland Ophthalmological Society. It was on his motion, as a representative of the College of Physicians and Surgeons, that the Association of Baltimore Medical Colleges, in 1890, became a national organization at Nashville. He was a frequent contributor to the medical journals and to the proceedings of medical societies.



DR. AARON FRIEDENWALD.

Andrew M. Armstrong. M.D. Willoughby Medical College, Fairfield, N. Y., 1832, one of the oldest physicians in Ohio, died at his home in Doylestown, August 21, aged 94. Dr. Armstrong located in Doylestown in 1837, and practiced his profession there for over sixty years. In 1880 he was elected to the state legislature, serving two terms.

Ellis Clarence Garee, M.D. College of Physicians and Surgeons, Baltimore, 1890, died at Baltimore, from typhoid fever, August 30, aged 41. He was a health warden of the city and president of the Southwest Baltimore Improvement Association.

George Whitfield Kemper, M.D. University of Pennsylvania, Philadelphia, 1836, died at Madison Hall, Port Republic, Va., August 19, aged 87. He had practiced in Rockingham County continuously for sixty years.

Edward N. Riggs, M.D. Cincinnati College of Medicine and Surgery, 1874, died at his home in Bridgeport, from the effects of a self-inflicted gunshot wound of the head, August 21, aged 57.

Philip Shaffer, M.D. Rush Medical College, Chicago, 1864, died at his home in North Manchester, Ind., August 22, after an illness of several months.

Frank J. Seabourne, M.D. Medico-Chirurgical College, Philadelphia, 1899, died, August 17, at his home in Bordentown, N. J., aged 33.

Jacob K. Hecker, Jr., M.D. Medico-Chirurgical College, Philadelphia, 1901, died at his home in Philadelphia, August 13, aged 27.

Miscellany.

No physician can afford to be indifferent regarding the accurate filling of his prescription.—*St. Paul Medical Journal.*

Tests of Uric Acid Solvents by Solubility of Their Urates.—Vicario reports in the *Gaz. des Hop. de Toulouse*, No. 22, that assuming the efficacy of a uric acid solvent to be proportional to the solubility of the urate which it forms, lycetol takes the highest place, lysidin second, while piperazin and urotropin came third in his tests. They were followed in turn by potassium bicarbonate, lithium carbonate and sodium bicarbonate. Lycetol is the tartrate of dimethylpiperazin.

A Remarkable Case of Fecundity.—"At the present time when so many medical writers are deploring the fact that so large a proportion of our native women refuse to bear children, it might be well to record the case of one who has done more than her share of duty toward the state." Thus speaks the *Medical Age* and tells of an intelligent American-born woman of 43, who was married at 13, and in these 30 years has borne 24 children, of whom 20 are living. The question arises: Are these children all of such health and character that the birth and rearing of each was really a service to the state?

Opium Eating in Hawaii.—Hawaii is said to be a paradise for the opium eater. Nowhere else is its sale so unrestricted or its use so widespread as in this territory since its annexation. Under the provisional government opium was in the sole control of the Board of Health. After annexation these laws were declared obsolete, and, according to the *Boston Transcript*, there is no restriction now as to the use of the drug or its sale. Nearly as much of the drug is taken to the islands as to the entire United States. An effort is to be made to enact some law against its use which will stand in the courts.—*American Medicine.*

Treatment of Lupus by Potassium Permanganate.—A recent Paris thesis states that Hallopeau has been very successful since 1900 in treating lupus with permanganate. He applies it as a powder on non-ulcerated lupus after washing the patches with soap and drying. He covers with dry cotton and leaves it for 15 minutes. He then rinses it off with warm water and applies a wet compress. A single application is usually sufficient, if not it can be repeated after an interval of a few days to allow healing and cicatrization. He sometimes uses a 1/50 solution, applying it on a compress and covering with oiled silk for 15 minutes. It is then rinsed off and replaced by a wet compress. This is repeated every day until cure is complete. The solution is not painful but the powder causes slight smarting, and in two cases the pain was severe until cocain or chloral was applied.

Meat-Juice and Marking Ink.—Of all places in the world a hospital for the sick should be administered with rigid attention to detail and order. That such is not always the case is abundantly shown by the reports of the coroners' courts. Hardly a week elapses without the tale of some death in a public institution of the kind due to gross negligence and want of method. Not very long ago we commented severely upon the carelessness which allowed strong carbolic acid to be left lying about in a ginger-beer bottle at one of our leading London hospitals. The result was the death of a workman who took a pull at the bottle under the impression it contained some harmless beverage. The latest scandal of the kind comes from the fever hospital near Bromsgrove, where marking ink was given in mistake for meat juice to two scarlet fever patients. Will it be believed that in a public hospital marking ink was habitually kept in a meat juice phial and left where it could be administered to a patient! It is all very well for a hospital committee, wise after the event, gravely to censure a nurse for stowing away the marking ink along with medicines and food. The fault lies with the system, or lack of system, that allows marking ink to be placed in any but a properly labeled and distinctive bottle of its own. Most marking inks are poisonous. It would be interesting to know what are the ward regulations at the Bromsgrove Infectious Hospital regarding poison bottles and poison cupboards; or do the dispensers utilize odd bottles and phials for all poisons needed in the wards?—*Med. Press* (London).

The Food of the Infant.—It is all very well to say that an infant shall be fed day after day, week after week, month after month, a certain definite amount of food of a certain exact composition, at times regulated by the clock. . . . On the other hand, the perfectly healthy growing child should be allowed some choice as to the quantity, time and quality of its food. In the first place, the child should be satisfied after taking its bottle, so that the quantity should be somewhat adjusted by the capacity of the child's stomach. An excess in quantity is very soon indicated by regurgitation. The strength of the milk should be frequently increased, so that the child shall take the strongest milk that it can comfortably digest, and if a child is restless and hungry before the set time is up anticipation of the time of feeding will often save a nervous strain and consequent sleeplessness and restlessness, and so be a blessing to everybody. I not infrequently see children who are perfectly healthy, and yet are a burden to their whole family connection on account of sleeplessness and restlessness, when the entire trouble is that the children do not get enough to eat. They are being fed according to some very strict system, and they have probably outgrown the formula used for the modification of the milk. They are not getting enough to satisfy them, and the feedings are separated by a period of perhaps four hours, which is about the limit that any baby will stand. Let these children gorge themselves a few times with a large quantity of good food, even if they do regurgitate a little, and they will then have a few good sleeps, and the whole picture will change.—Bishop in *Medical Critic*.

Prophylaxis and Treatment of Affections of the Biliary Passages.—W. N. Clemm of Darmstadt states that the main point in prophylaxis is to maintain an almost continuous flow of bile by taking the food in such a way as to elicit a constant production. In case there is any stoppage of bile, the flow should be restored by energetic deep breathing, light massage or the rolling of the ball proposed by Rose and others for chronic constipation. All catarrhal gastrointestinal affections should be thoroughly treated. A glass or two of milk should be taken before rising in case of the slightest suspicion of stoppage of the flow of bile. While dressing, one or two cups of very hot physiologic salt solution should be sipped, and after exercises in deep breathing, a twenty to thirty minutes' walk in the open air should follow. There should not be more than two or two and a half hours' interval between meals, with milk between at least twice, and the deep breathing exercises should be repeated before dinner and before retiring. The patient should sleep on his left side to promote the flow of bile and the emptying of the large intestine. Abrupt movements should be avoided and the earliest and last meals should be principally albumin and fats. These measures should be supplemented by taking for at least three months at evening and morning and, during an attack, also at noon, .75 gm. of sodium oleate in solution, not pills, with or without tincture of valerian or validol. The sodium oleate or eunatrol has a cholagogue action and softens the gallstones and dissolves cholestearin. During a severe attack he advises Carlsbad water as hot as it can be sipped, taken every ten to fifteen minutes up to six or eight glasses, supplemented by flaxseed poultices to the region, while the patient reclines for three hours morning and afternoon.—From *Wiener Med. Presse*.

Clippings from Lay Exchanges.

THE NEWS FROM WATER VALLEY.

"We are glad to state that Mrs. Beulah Hutcherson is improving slowly, she has been confined to her room for eight weeks with Dr. Walker her attending physician.

"Mr. Ab Roach is still very feeble and not able to sit up, many are having chills.

"Mrs. Mary Booker is also very sick, she has been confined to her room for some months and is gradually growing weaker each day.

"Dr. Arnold is now making his home at Water Valley, he seems to be a very prominent young physician. The death angel visited the home of Mr. James Jones the 11th and called him away from his wife and three children. Mr. Jones has been for some time a victim to that great disease consumption, a week before he died he had an attack of meningetis and suffered oh so much, but we would say to his friends and relatives that we trust his sufferings are over for he seemed to be reconciled to die, said he was ready; what a blessed thought. Grieve not dear friends as your loss is his gain. He was buried at Finch Graveyard near Alexander with Brother Hensley and Gray conducting the funeral service, there was a very large crowd in attendance.

"Professor Beasley has moved to Etna Furnace, and is practicing medicine there, the people were very much disappointed in regard to his quiting his school so early as he only taught one month."—*Columbia* (Tenn.) *Democrat*, May 16, 1901.

REMARKABLE OPERATIONS.

"Eyes Removed from the Head, Washed and Restored to their Place—Sight Followed.—Toledo, O., April 17—Two remarkable operations on eyes were performed at St. Vincent's hospital. M——'s eyes had been destroyed in an explosion of gunpowder about 12 years ago, and since that time he has been totally blind. The physicians yesterday removed the blind eyes from their sockets, rubbed them, cut off a scum that had accumulated, and replaced them in their sockets.

"M—— blinked for a few seconds, rubbed his eyes and to the astonishment of everybody present, announced that he could see as well as he did before his eysight was destroyed. The physicians tested him for a few minutes in regard to color, and gave him knot of spun wool in varied hues to make comparisons and selections from, and he did so without a mistake. After the tests the physicians darkened the eyes so that the light might not destroy them.

"Another equally as startling an operation was that on P. F. W.'s 16-moths-old baby, which was born blind. The same physicians removed the eyes of the child, cleaned them, cut off a scum that resembled the shell of a nut, and then replaced the eyes. To the surprise of everybody the child began to observe things."—*Newark* (Ohio) *Tribune*, April 17, 1902.

A METALLIC SURGEON.

"Tom V—— of Mattoon was in the city Tuesday. Mr. V—— is manufacturing an aluminum surgeon's chair that is meeting with great sales. . . ."—*Greenup* (Ill.) *Press*, March 13, 1902.

TUBERCULOSIS AND PHTHISIS.

"Tuberculosis of the lungs carried off twenty-five of the victims of disease last month. Seven others died of tuberculosis and four of phthisis."—*Los Angeles* (Cal.) *Express*, Aug. 6, 1902.

GASTRONOMIC SURGERY.

"Dr. ——, who has been in Touro Infirmary for some time, being treated for cancer of the stomach, has been gradually getting worse. . . . It is feared that the patient will die under the knife, but it has been decided to attempt the operation as a last resort.

"This is a most interesting case from a scientific point of view, as the result may revolutionize gastronomic surgery."—*New Orleans* (La.) *Picayune*, Sept. 14, 1901.

LAPAROTOMY OF THE INTESTINES.

"The annual meeting of the New London County Medical Association was held Thursday afternoon. . . . Dr. —— of Norwich followed with a paper describing his now famous operation of laparotomy of the intestines."—*Norwich* (Conn.) *Bulletin*, April 4, 1902.

A WARNING TO CACHINNATORS.

"Westville, Ind., man rips his lining while cachinnating and condition is serious. La Porte, Ind., Dec. 6.—(Special.)—If

—— of Westville, this county, recovers he will eschew laughing. Yesterday his risibilities were affected to such an extent that he laughed so hard the inner membranes were torn loose from his lower ribs, according to the claims of the attending physician."—*Chicago Tribune*, Dec. 7, 1901.

WAS HE A SURGEON?

"Dr. ——, one of Huntsville's oldest citizens, died last evening at ten minutes past seven o'clock after suffering about two weeks with paralysis of the brain. . . . For many years he was one of the leading butchers of Huntsville, but during recent years he has spent his time in retirement."—*Huntsville* (Ala.) *Mercury*, Aug. 8, 1902.

CYSTED ABDOMIAL ABSCESS REMOVED.

"Monday, Drs. —— of Vincennes and —— of this city performed a delicate surgical operation on —— in this city. Six months ago —— was injured in the abdomial regions from which a cysted abscess formed. The physicians above mentioned made an incision and removed a large abscess almost the size of a gallon vessel."—*Lawrenceville* (Ind.) *Republican*.

DID SHE CATCH THE CAR?

"B. —— entered suit against Dr. —— for $50,000 damages. . . . She alleges the defendant was called to her home, December 19, 1900, to attend her and that he carelessly and negligently treated her, and then abandoned her while she was suffering great agony to catch a car."—*Pittsburg* (Pa.) *Dispatch*, Nov. 16, 1901.

(To be continued.)

Societies.

COMING MEETINGS.

Wyoming State Medical Society, Cheyenne, Sept. 9-10, 1902.
Medical Society of the State of Pennsylvania, Allentown, Sept 16-18, 1902.
American Association of Obstetricians and Gynecologists, Washington, D. C., Sept. 16-18, 1902.
Medical Society of the Missouri Valley, Sioux City, Iowa, Sept 18, 1902.
American Dermatological Association, Boston, Sept. 18-20, 1902.
American Academy of Railway Surgeons, Kansas City, Mo., Oct. 2-3, 1902.
Medical Association of District of Columbia, Washington, Oct. 7, 1902.
Idaho State Medical Society, Moscow, Oct. 9-10, 1902.
Vermont State Medical Society, Burlington, Oct. 9-10, 1902.
Mississippi Valley Medical Association, Kansas City, Mo., Oct. 15, 1902.

Woodford County (Ky.) Medical Society.—This society was organized at Versailles, August 15, with the following officers: Dr. John C. Lowry, Troy, *president*, and Dr. William C. McCauley, Versailles, secretary.

St. Louis Medical Society of Missouri.—The committee on Osler memorial address announces that Prof. William Osler of Johns Hopkins University, Baltimore, will deliver a memorial address on "William Beaumont, the First and Greatest American Physiologist," October 4.

Mississippi County (Ark.) Medical Society.—This society was reorganized last month, under the new constitution and by-laws, required by the American Medical Association, through Arkansas State Medical Society, and is officered as follows: Dr. Thomas G. Brewer, Osceola, president; Dr. Charles A. Turner, Osceola, vice-president; Dr. H. Clay Dunavant, Osceola, treasurer, and Dr. George A. Hennings, Butler, secretary.

Prince Edward Island Medical Society.—The annual meeting of this society was held at Charlottetown, July 9. After the general business was transacted, the society adjourned in order to attend the meetings of the Maritime Medical Association, which were being held at the same time and place. Dr. Frederick F. Kelly was elected president; Dr. Peter Conroy secretary, and Dr. Robert B. Shaw treasurer, all of Charlottetown.

International Surgical Association.—The approaching congress of the Belgian Surgical Society to be held at Brussels September 8, is to be distinguished by an earnest effort to organize an international surgical association. Dr. C. Willems, the president of the congress, is the prime mover in the matter. One of the aims of the international association is to establish a uniform outline for the study of the most important questions in surgery and to discuss them on a common basis.

French Medical Society of North America.—The first meeting of the French Medical Society of North America at Quebec, June 25 to 27, was mentioned in this column August 23. The next meeting is to be held in Montreal in 1905, under the following officers: President, Dr. A. Achille Foucher, Montreal; vice-presidents, Drs. Michael J. Ahern, Quebec; A. Wilfred Petit, Nashua, N. H., and Dr. Edward H. Rouleau, Calgary, N. W. T., and general secretary, Dr. Lesage, Montreal.

International Congress for the Care of the Insane.—This congress, now in session at Antwerp, is discussing the questions of the care of the insane at home and in institutions; which classes of insane belong in institutions; the scientific and economic fundamentals of the organization of official colonies and institutions for the insane, are the reasons for organizing new colonies, and the best means of founding and establishing such. Dr. F. Sano, rue Montebello 4, Antwerp, Belgium, is the secretary of the congress.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Granular Conjunctivitis.

B. Melconian, according to an abstract in Amer. Med., states that an application of a solution of iodin produces more satisfactory results in granular conjunctivitis than any other medication. He recommends the following:

℞.	Metallic iodi	gr. i	|06
	Liq. vaselini	℥i	30|

M. Sig.: To be used locally.

The foregoing solution may be modified to suit the case. In acute cases or in young individuals, the quantity of iodin should be reduced one-half. The affected eyes should *first* be cleaned with a tampon dipped in a boric acid solution. The lids should then be turned and the iodin applied to the granular areas by means of the end of the finger in order that light massage may be given to the lid at the same time. The lids should then be kept closed for five or ten minutes and protected from dust and strong light. This treatment should be repeated morning and evening and in the middle of the day one or two drops of the solution should be instilled into each eye as a collyrium, which may be *followed by light massage* over the closed lids. The author states that immediately after the *treatment* the eyes become red, there is lachrymation and some photophobia. These symptoms disappear in from one-half to one hour, as a rule. In some cases, however, the symptoms persist for several days. In such cases the treatment should be begun with a 1 per cent. ointment of yellow mercuric oxid. This treatment, he states, should be continued for three to six months.

Dropsy Due to Heart Disease.

According to the *Cyc. of Med.* digitalis is contraindicated in marked atheroma of the blood vessels, aneurism, apoplexy and other states of arterial excitement and in gastric irritation. The following *combination is, however, recommended* in dropsical conditions caused by an incompetent right heart:

℞.	Tinct. digitalis	ʒi	4
	Tinct. scillæ	ʒii	8
	Spts. juniperis co.		
	Pot. acetatis, āā	ʒiv	16
	Vini albi q. s. ad	℥vi	180

M. *Sig.: One tablespoonful three or four times a day;* or:

℞.	Pulv. digitalis		
	Pulv. scillæ, āā	ʒss	2
	Pot. nitratis	ʒi	4

M. Ft. pil. No. xxx. Sig.: One pill three times a day.

Prostatic Disease.

J. H. Dowd, in an abstract in *Med. Standard*, has introduced a new psychyrophore for the direct application of hot water to the prostate gland through the rectum. The instrument has a collar of hard rubber where it is grasped by the sphincter, thus making it a non-conductor of heat and making it possible to use much hotter water. Although pure water alone may be used, it is better to use the normal saline solution at a temperature of 100 to 110 F. To promote absorption of the inflammatory exudate the author recommends the use of the following suppository, to be inserted as soon as the tube is withdrawn.

R.	Ichthyol	gtt. ii	12
	Ext. belladonnæ	gr. ¼	015
	Ext. hyoscyami		
	Pot. iodidi. āā	gr. i	06

M. Ft. suppos. No. i. Sig.: To be inserted as directed.

Hemorrhages in Infectious Diseases.

Roger, in *Jour. des Praticiens*, as noted by *Amer. Med.*, states that in hemorrhages from the lungs and kidneys during the infectious diseases, the patient should be immobilized and bathing discontinued. If the patient is restless, delirious or if there is much cough he should be calmed by opiates. Following these precautions, acid drinks such as citric or sulphuric lemonade are often prescribed to increase the coagulability of the blood. The following has been used in hemorrhagic smallpox:

℞.	Acidi sulphurici		
	Alcoholis, āā	ʒss	2
	Syrupi	℥iii	90
	Aq. destil.	℥xiii	390

M. Sig.: To be used as a drink.

Calcium chlorid has, in some cases, given good results. This preparation, however, can not be employed hypodermically as it causes sloughing and eschars. The author prescribes it in doses of one dram daily, which is usually sufficient to control the hemorrhages, although the dose may be increased to three drams daily. He recommends it in the following form:

℞.	Calcii chloridi (crys.)	ʒi-iss	4-6
	Rum	℥i	30
	Tinct. cinnamomi	ʒi	4
	Aq. destil.	℥ii	60

M. Sig.: To be taken, during twenty-four hours, in divided doses. The alcohol should be omitted if lesion of the kidney exists. In hemorrhagic nephritis the hematuria disappears rapidly in two or three days. When the source of hemorrhage is accessible, very hot or very cold applications may be employed. Hemorrhages from the mucous membranes may be arrested by the application of antipyrin, which produces local constriction. Alum, tannin and rhatany are the astringents usually employed. *According to his statement*, Carnot has had good results from the use of the following in vaginal and nasal hemorrhages:

℞.	Gelatin (white)			
	Sodii chloridi, āā	ʒiiss	10	
	Hydrarg. bichlor.	gr. viiss		50
	Aq. destil.	℥iiiss	105	

M. Sig.: *Apply locally.*

Continuous Vomiting of Pregnancy.

M. R. Condamin, in *Indian Med. Record*, advises absolute rest of the stomach with complete suppression of all liquid and solid nourishment for eight or ten days. During this time three or four quarts of artificial serum are injected daily, preferably into the rectum. If intolerance should appear on the part of the rectum a few drops of laudanum may be added to the serum, or it may be administered subcutaneously. About the tenth day a few swallows of liquid food may be allowed, and the ordinary diet may be gradually resumed. The author reports one typical case, and believes that many cases may be carried to term in this way, in which, otherwise, abortion would result or would have to be induced.

Dietetic Treatment of Summer Diarrhea.

Dr. L. Fischer, in *Med. Record*, states that it is frequently necessary to stop milk feeding in cases of diarrhea of children or in the presence of fever or gastroenteric disorders. In such cases the author recommends for temporary use when vomiting or diarrhea persists either barley water, four ounces, or oatmeal water, four ounces, to be given every two or three hours. The feeding may be sweetened with granulated sugar half a teaspoonful to each bottle, or if fermentation is present as demonstrated by colic, eructations or green stools, half a grain of saccharin may be substituted for the sugar. To make barley water, Dr. Fischer recommends one tablespoonful of ground barley flour be added to one pint of water. This should be boiled for half to one hour, strained and enough water added to make a pint of barley water. If constipation should follow the use of the barley water, one teaspoonful of glycerin added to each teacupful of barley water will make it more palatable and will usually correct the constipation. Oatmeal water may be prepared in the same way as barley water. In cases where the child is underfed the white or yolk of a raw egg, well beaten, may be added temporarily. Whey feeding is necessary in some cases. His formula for making whey is as follows: Take a half pint of fresh milk heated luke warm (115 F.) and add one teaspoonful of essence of pepsin and stir slightly. Pour into custard cups and let it stand until it curdles; then beat with a fork until the curd is finely divided and strain. The whey may be administered as follows: For an infant under six months:

Whey, ℥ii; milk, ℥i.

Warm to 100 F. for three minutes and feed. This amount may be given every two or two and one-half hours.

For a child two to four months old:

Whey, ℥ii; milk, ℥ii.

Sig.: To be given every three hours. If this is well borne, it can gradually be increased to two and a half ounces of each. Or if the child appears hungry after feeding three ounces of each may be given once in three hours. The author states that some infants three months old can easily take six ounces of food. The weight should be noted, and if the child does not thrive properly the amount of milk may be increased and the whey decreased.

Infantile Diarrhea.

The following is recommended by H. C. Hahn in *Jour. des. Pract.* in the treatment of diarrhea of infancy:

℞.	Tinct. iodi	gtt. x-xv	65-1.
	Syr. simp.	℥ss	15
	Aq. destil. q. s. ad	℥v	150

M. Sig.: One teaspoonful every two hours.

Neuralgia.

The following combination is recommended by *Prog. Medical* in the treatment of neuralgia:

℞.	Ext. hyoscyami		
	Ext. cannabis ind.		
	Pulv. aconiti rad.		
	Pulv. belladonnæ rad., āā	gr. 1/3	02

M. pilula No. i. Sig.: One to three such pills daily.

Medicolegal.

Waiver of Privilege by Applicant for Insurance.—Where an insured, *on behalf of himself and those claiming an* interest in the policy, waived the provisions of law forbidding any physician or surgeon from disclosing *information* acquired while attending him in a professional capacity, the Court of Appeals at St. Louis holds, in Keller vs. Home Life Insurance Company, that such waiver was binding on the beneficiary in a suit on the policy, and that it was error for the trial court, in this case, to exclude testimony concerning the state of health of the insured by physicians who attended him shortly before his application. It is settled law, the court says, that a patient may waive for himself the protection of secrecy imposed by the Missouri statute (section 4659 of the Revised Statutes of 1899) on the physician or surgeon who attends the patient in a professional capacity, touching the disclosure of facts acquired by the former in that intimate relation. And if the patient himself may make such a waiver in advance, as seems in accord with principle, the court says that it does not see why he may not make such a waiver an element of his contract of insurance, and, having done so, the waiver will be binding on all who come within its terms. In other words, such a waiver may be made in advance, as in this instance, so as to be binding on a beneficiary of the contract other than the party making the waiver.

Appeal from Decision of Board of Medical Examiners.—The Supreme Court of Montana says, in State ex rel. Riddell and others, State Board of Medical Examiners, vs. District Court, that it was urged that a notice of an appeal to the District Court from a decision of the board should have been entitled by the name of the party appealing vs. The Board of Medical Examiners of the State of Montana, and that not being so entitled, it was not sufficient to give the District Court jurisdiction of the appeal. But the Supreme Court holds that there was no merit in this contention. It says that section 1892 of the Code of Civil Procedure provides, "An affidavit, notice or other paper, without the title of the action or proceeding in which it is made or with a defective title, is as valid and effectual for any purpose as if duly entitled, if it intelligibly refer to such action or proceeding." Though the proceeding on the appeal in such cases as that under consideration is not properly an action, in the strict sense of the term, but a special proceeding, it should, perhaps, have been entitled as contended; yet the failure of the clerk to so entitle it did not affect the merits of the controversy. Then it did not appear whether the board was represented at the trial. However, this was of no moment, the Supreme Court says, the notice in the case having been sufficient to meet the requirements of the statute. It contained intelligible reference to the decision of the board, by which the party appealing felt aggrieved, and his purpose to appeal therefrom. That the board allowed the appeal to go by default, if such be the fact, did not affect the case. Furthermore, upon the theory that the board was the person aggrieved by the action of the District Court in reversing the action of the board and declaring the applicant entitled to a certificate, the proper course to be pursued by it was to appeal to the Supreme Court from the judgment, as provided in the statute, or to move for a new trial. Under the statute no formal pleadings are required. Wherefore, the district had jurisdiction of the appeal from the board, and to render the particular judgment stated, and the board's application for a writ of certiorari must be denied.

Failure to Introduce X-Ray or Expert Evidence.—According to the fourth appellate division of the Supreme Court of New York, the party suing in the personal injury case of Kane vs. the Rochester Railway Company testified or gave evidence tending to show that his side was injured in such manner that a hernia resulted; that three fingers of the left hand and two of the right were put out of joint, and that his wrist was seriously injured, constantly pained and troubled him, and was in such condition at the time of the trial, two years after the accident, that he had to keep a leather bandage constantly around it when at work, stating that he could not use the wrist in his work without such bandage, which was exhibited to the jury. There was a sharp controversy between the medical experts as to whether or not any hernia existed; but they all agreed that at the time of the trial there were no objective symptoms of injury to the fingers or wrists that would account for the weakness and pain complained of and testified to by the party suing, and that, if there was any difficulty with the bones, an *x*-ray examination would disclose it. Upon the cross-examination of the party suing, it appeared that a certain physician made an *x*-ray examination of his wrist and fingers, and the physician, who was called by the party as a witness, testified upon his cross-examination that he did make such examination, and that he took *x*-ray photographs of the same, and that he then had such photographs, or the plates, in his possession; that he made the examination and took the photographs in December, 1899, or January, 1900. The accident occurred June 25, 1899. The party's counsel did not ask him or the physician what the *x*-ray examination disclosed as to the condition of the fingers or wrist, nor offer to produce the photographs showing their condition. The court holds that it was reversible error not to give a requested instruction to the jury substantially to the effect that, it appearing that the physician made an *x*-ray examination of the party's fingers and wrist, at his request, and the party having omitted to ask the physician, when called to the witness stand by him, what he discovered from such examination, the jury had the right to assume that the physician's testimony, if given, would have been adverse to the party upon that point. The court says that it was no answer that the company called out the fact that the *x*-ray examination had been made, and might have asked what the result of such examination was. It was not called upon to take the chances of an answer by a hostile witness. It was not bound to prove its defense by the other party's expert physician, who, at such party's request, made a careful examination of the injured parts to ascertain the extent of their injury; and the burden was upon the party suing not only to produce him, but also to interrogate him as to facts within his knowledge relating to the important issue, or expose himself to the hazard of unfavorable inferences. A party seeking to recover for serious injury to his side and wrist ought not to be permitted to call as a witness an expert physician, who at his request examined and learned the condition of both, and interrogate him only as to the condition of one, without exposing himself to the hazard of having the jury infer that, if the witness had been asked as to the condition of the other, his answer would have been unfavorable to the party calling such witness.

---

1. **Treatment of Chronic Nephritis.**—The method advocated by Rochester is stimulation of the excretions, the use of the stomach tube and hot-air baths. The technique of such a bath at home is very simple. The patient is placed entirely nude between blankets in bed covered by two extra blankets, and steam or hot air is introduced through a nozzle in the blankets and bed-covering. He reports six cases, several of them treated by hot air or steam baths with benefit, and remarks in regard to the surgical treatment that in progressive signs of kidney degeneration shown by persistent increase in albumin when it should be diminishing, surgical procedure seems worthy of consideration, but as a method of treating true chronic nephritis it is entirely out of place. The prognosis in given cases of chronic nephritis depends on the secreting power that may be developed in the kidney with proper treatment and is also materially affected by the condition of the circulatory apparatus. If the arteries are much diseased and the myocardial nutrition interfered with the prognosis is not good even though we may be able to cause free excretion through the skin and bowel. If there is no decided atrophy of the sweat glands interfering with their hypersecretion the prognosis is not good, and an excessive degree of anemia unimproved by treatment is also of bad signification as well as is the frequent occurrence of marked uremic symptoms. We should not try to stimulate into activity an organ that is inflamed or degenerated, by the use of drugs that excite functional activity of that organ. Therefore, we should rarely have recourse to stimulating diuretics or those which increase the arterial pressure. The diet should be looked after; the chief ingredient should be milk. In acute exacerbations or in uremic states milk should be the only article of food. To aid metabolism exercise is necessary; massage where active exercise is impossible should be employed. The dilution of catabolic materials by drinking large amounts of distilled water or one of the mildly alkaline mineral waters is also advised. When toxemia exists, with defective kidney action, wet cupping of the loins, a full dose of calomel, followed by a saline, and hot-air baths employed once or twice daily, preceded if necessary with a small dose of pilocarpin 0.003 to 0.005 gm. After the bowels have thoroughly moved there should be given hypodermically once or twice a day 500 to 1000 c.c. normal salt solution.

2. **Strychnin.**—In his preliminary communication, Salant has found that strychnin is not detectable in the stomach or intestinal canal of rabbits, and he calls attention to the practical bearing of this fact on its application in the human subject.

4. **Angina Pectoris.**—After reporting five cases, Perkins discusses the general subject, which he considers to be rather a disease entity than a group of symptoms. When its diagnosis is only the placing of the individual case under the proper head of true or pseudo angina, it is somewhat difficult, that is, diagnosing organic lesion from toxic-hysteria or vasomotor disturbances. In two of his cases he has some question whether the latter condition did not exist. The most important thing in the treatment is to search out the cause of the disease, the cause of the attacks and their relief. The iodid of potassium seems to be the most valuable drug given in moderate doses, 10 to 15 grains three times a day, for a long time. During the attack nitroglycerin is best in many cases, but frequently the only drug that will give relief is morphin, and sometimes a great deal of it. If the pain is not soon controlled by this, to avoid the possibility of its sudden overaction on cessation of pain he would use chloroform or ether.

10. **Treatment of Acute Rheumatism.**—Admitting that rheumatism is due to specific bacterial poisoning, Thomson asks what we can do to arrest the growth of the organism. He doubts that the salicylates have such an effect. In very many cases he believes that rheumatism is preceded by tonsillitis through which the microbes get into the system. His own observations would rate this frequency as high as 25 per cent. Much he thinks can be done by proper prophylaxis in this direction. Another fact in acute rheumatism is the development of remarkable sensitiveness of the skin and he ascribes the profuse sweats of this condition to the cutaneous nerves as much as to the presence of the poison in the blood. We should, therefore, treat the skin. All patients with rheumatic fever should be dressed in flannel and lie between blankets from the very first, and extra precautions be taken with the precardial surface for the same reason. He thinks that sedulous attention to the skin would prove a much better preventive of tedious relapses than the dosing with drugs, and as a prophylaxis to susceptible persons he speaks highly of the old Greek custom of daily bodily inunctions, especially of the feet. The alkalies are not curative of rheumatic fever, but an alkaline condition of the blood is a great safeguard against carditis, and they should not be withheld when the least signs of attending heart trouble develops. The anemia caused by rheumatic toxin is *sui generis*, and iron, instead of curing it, is mischievous. Cod liver oil does much better. Small doses of arsenic also sometimes seem to be of use. He has said nothing about the salicylates because they do not need recommendation. He prefers the strontium salt as being the least depressing and of equal efficacy when given in the same dose. In tedious subacute cases it is often advantageous to omit the salicylates altogether and prescribe lemon juice instead.

11. **Symptomatology and Diagnosis of Acute Articular Rheumatism.**—In considering the differential diagnosis, Weber specially mentions first the acute gonorrheal arthritis which may be multiple, but is more often monarticular, caused by the gonococcus and staphylococcus. It does not react upon salicylates, a helpful fact for diagnosis, which is an important point. He thinks it rather frequent, and there may also be a rheumatic arthritis complicating gonorrhea. Septic arthritis, puerperal or otherwise, from streptococcus infection, is generally purulent. The secondary multiple arthritis of acute infectious diseases, scarlatina, dysentery, cerebrospinal meningitis, perhaps also in rare cases of severe syphilis, will be recognized by careful examination of the history of the case. He had a case of multiple neuritis which had a close resemblance to acute rheumatism as far as pain and tenderness in

6. **Plague as a Soil Infection.**—Farrar remarks that plague is epidemic in certain districts of China. Given two villages not more than 500 yards apart, under precisely the same conditions as to elevation, exposure, etc., one may suffer and the other remain exempt. It is difficult to believe, with the mortality that we have, that plague epidemics remain strictly local, and that in spite of the nomadic habits of the people. The policy successfully adopted in India in dealing with epidemics has been that of evacuation, a policy fully sanctioned by the most enlightened experience. The removal of the inhabitants of an infected town to camps has magical effects. Farrar is inclined to think that the soil becomes infected and that infection takes place largely through going barefoot. Europeans who wear shoes are rarely affected, and this is true not only in regard to the ordinary population, but those who have to do with plague cases. He is, therefore, inclined to think that there is a soil infection and that direct personal contagion of the disease except through pneumonic cases is very rare.

9. **Pulmonary Tuberculosis.**—Latham reviews the treatment of pulmonary tuberculosis, calling attention to the futility of various remedies which have been employed from time to time and the importance of exercise, ventilation, etc., and good feeding, as can be best obtained in a sanatorium where no drugs are used in the routine management of cases, but only to meet complications such as hemorrhage, diarrhea, etc.

11. **Typhoid Inoculation.**—This statistical study by Crombie appears to show that a single inoculation has some protective power, but a double inoculation increases the susceptibility to the disease.

12. **Appendicitis.**—O'Conor insists on certain points: 1. As to the uselessness of allowing local suppuration to take its course in appendicitis. He does not think there is much danger in separating adhesions from the presence of pus; adhesions are only there to meet the conditions, and when these are removed they dissolve of themselves in many cases. He believes in a large incision, three or four inches, in opening appendiceal abscess and in cases of non-purulent appendicitis he makes a two-inch incision, which can be extended if the appendix can not be brought easily to the surface.

15. **Report on Apollinaris Water.**—The Academy passed on in 1868 and admitted Apollinaris water to France as a natural mineral water of a certain composition. The water has changed slightly since then and it is now artificially charged, so the Academy passed a resolution accepting the report of the committee to drop it from the list of natural mineral waters.

16. **Metalloid Iodin in Therapeutics.**—Billet has tried to remedy the fact that iodin in the officinal preparations in benzine, carbon sulphid and chloroform is not in a metalloid state. He endeavored to find some substance to combine with it which would not alter the physical nor chemical properties of the iodin. He found that these conditions were fulfilled by a special petroleum ether composed of pentane and hexane, which distils below 55 C. and boils below 60 C., with a density of 0.628 to 0.630. The solution is stable and the iodin in it retains its natural state and all its bactericidal and antiseptic properties. This ether will dissolve 60 gm. of iodin to the liter. He usually prefers a solution of bi-sublimated iodin, 25 gm. to 1 liter of this petroleum ether distilling below 55 C. This solution has no caustic properties and can even be applied to the face and sprays readily. The ether dissolves the fatty matter in the skin and by its superior osmotic powers penetrates to a remarkable depth and carries the iodin with it. The ether evaporates almost instantly and the iodin is deposited in the form of crystals.

17. **Gelatin in Food as Treatment for Deficient Plasticity of Blood.**—The authors of this article attribute the phenomena of glycosuria, albuminuria and hemophilia to a primary alteration of the blood, entailing some modification of its density, and they suggest as treatment the ingestion of a certain amount of gelatin. It is readily absorbed through the stomach and 15 gm. a day can be taken in this way without inconvenience. It has shown remarkable efficacy in controlling the tendency to hemophilia. In albuminuria and diabetes the effect is transient, that is, it ceases with the suspension of the gelatin, which should therefore be given more or less continuously. Lancereaux welcomes this new utilization of the coagulating and hemostatic properties of gelatin as a valuable contribution to therapeutics, effective while absolutely harmless.

18. **The Eruption at Martinique.**—Kermorgant summarizes the reports presented by the medical officers of the colonial troops at Martinique in regard to the eruption. In Saint Pierre every one was killed, the clothing burned completely off, the limbs detached in many instanes and the skulls burst and empty, the contents expelled through wide cracks. In some of the victims the abdomen had burst while the intestines depended intact. The tissues looked as if they had been burnt by a gas flame. The limbs were in exaggerated flexion, the hands in some of the cadavers twisted back on the forearm and this again on the upper part of the arm, while the head and trunk were almost invariably in actual opisthotonos. About two miles out from the city the victims seemed to have succumbed more to suffocation than to fire. The clothing was not all burned off, and parts of the body were intact. Farther still from the scene of the explosion the lesions were less severe and a large number of the victims were taken on the gunboat Suchet to the military hospital at Fort-de-France. Nine died on the way and thirty-two were received in the hospital. All were intensely excited and suffering such pain that they groaned or screamed constantly, and some complained that they could not swallow and respiration was difficult. The nostrils were obstructed by volcanic mud and patches of it on the skin looked like brown sealing wax after the blisters had broken. Attempts to clean the pharynx brought away debris of exfoliated mucosa. Several who had exhibited symptoms of internal burns succumbed during the night or next day. One native, severely burned, died in intense fever with anuria, another whose feet were burned died from tetanus. A woman with burns of the third degree on the legs and thighs had a temperature of 40 C. after the eschars had fallen, although the wounds were healing perfectly; diarrhea with dysenteriform stools followed and double broncho-pneumonia, but no albuminuria or nervous troubles. She died also. All the wounds were dressed with picric acid, which did not induce any

symptoms of intolerance notwithstanding the large extent of surface on which it was applied. The patients were all relieved at once, and the repair of the tissues was rapid and almost entirely without suppuration. All the survivors had left the hospital by the twenty-second day, and two-thirds of those who had been received were dismissed cured without presenting the slightest retraction or vicious cicatrix, interfering with normal movements. The deaths at Carbet, between two and three miles from the scene of the explosion in Saint-Pierre, were evidently due to suffocation from inhalation of gases emitted by the volcano under great pressure, and so hot that they caused the instantaneous coagulation of the blood, such as was observed at the burning of the Opéra-Comique at Paris. It is equally possible that death was due to electric phenomena.

19. **Hermophenyl in Treatment of Syphilis.**—Hermophenyl is the name given to the mercury phenol disulphonate of sodium by Lumière, who produced it by the same technic as is used in the production of the cacodylates. Contrary to the ordinary products of mercury, it does not precipitate the albuminoids, is not precipitated itself by hydrochloric acid, hydrosulphate of ammonia nor sodium, and is not altered by a temperature of 120 C. (249 F.) A sheet of gold leaf left in a 5 per cent. solution of hermophenyl for forty-eight hours was not affected. It forms a white very soluble powder, containing 40 per cent. mercury. It is very slightly toxic, the fatal dose for a guinea-pig by the mouth is 20 cg. per kilogram and by subcutaneous injection, 125 mg. A 1 to 5 per 1000 solution arrests all vegetation and kills the principal micro-organisms, and even a 1 to 2 per cent. solution does not induce local irritation nor pain. Hallopeau reports that he has used the hermophenyl in 20 cases of secondary syphilis and found that its action was fully equal to that of the ordinary mercurial preparations, while it has the advantage that it can be administered in large doses by the mouth without causing digestive disturbances. At first he tried it on 30 patients in intramuscular injections but found the buccal administration preferable. His experience superposed on that of others, indicates that the new preparation will find a useful field in therapeutics to alternate with other methods of mercurial treatment or substitute them under certain conditions.

20. **The Calorisateur.**—Glover's instrument is for the application of medicinal substances to the upper air and digestive passages. A current of superheated air is driven into a non-volatile medicinal fluid, heating it, sterilizing it and expelling it in the form of a medicated spray at body temperature.

32. **Bovine and Human Tuberculosis.**—Wolff had occasion to observe a case of fatal primary tuberculosis of the intestines in a man of 63, a master cabinet maker. It fulfilled in every particular the conditions declared necessary by Koch for the assumption of a primary tuberculous affection of the intestines. Two guinea-pigs were inoculated with matter from the spleen and both developed tuberculosis. A calf was then inoculated with the tuberculous organs of one of the guinea-pigs, after negative reaction to the tuberculin test. The calf was killed eighty-three days after the inoculation, and the internal organs were found the seat of the typical lesions of a severe case of bovine tuberculosis, that is, Perlsucht. Wolff's experiences further confirmed the fact, as he describes in detail, that animals and persons infected with tuberculosis by way of the alimentary canal may develop typical tuberculosis without exhibiting the slightest macroscopic lesion in the intestines. This explains the rarity of primary intestinal tuberculosis. He is also convinced that the infection from substances ingested occurs by way of the mouth in the majority of cases, principally through the tonsils.

33. **Paraffin Prothesis.**—Eckstein extols the advantages of using "hard paraffin," not melting below 57 to 60 C. He slips a piece of rubber tubing over the syringe to keep in the heat.

37. **"Antimorphin."**—Analysis of this medicine advertised as a cure for morphin addiction, shows that it contains a considerable proportion of morphin.

38. **Peroral Intubation.**—The laryngeal tube extends beyond the teeth in Kuhn's peroral intubation. It serves not only as a laryngeal tube but also as a speculum for the upper-air passages, a gag and a dilator. He advises it for use in anesthesias, etc.

60. **Gelatin Injections and Their Dangers.**—Hirsch relates two cases in which subcutaneous injection of gelatin proved fatal, and has collected five others. This raises to seven the total of deaths from this source in Germany, all succumbing with symptoms of tetanus. He also reports nine cases in which the gelatin injections proved a life-saving measure, mostly in cases of protracted hemoptysis.

66. **Anesthesia with "Anesthesin."**—Kassel is enthusiastic in his commendation of anesthesin for various purposes. It has proved especially useful in his experience for persons with dysphagia from ulcerations in the larynx. The anesthesia induced lasts two to twelve hours. The patients can inhale the anesthesin through an ordinary small inhaler. It thus advantageously substitutes orthoform for the purpose.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

MASSAGE AND THE ORIGINAL SWEDISH MOVEMENTS. Their Application to Various Diseases of the Body. Lectures Before the Training Schools for Nurses Connected with the Hospital of the University of Pennsylvania, German Hospital, Woman's Hospital, Philadelphia Lying-in Charity Hospital, the Philadelphia Polyclinic and College for Graduates in Medicine, and the Kensington Hospital for Women, of Philadelphia. By Kurre W. Ostrom, from the Royal University of Upsala, Sweden. Fifth Edition, Revised and Enlarged, with 115 Illustrations. Cloth. Pp. 181. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1902.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume VIII. Pediatrics and Orthopedic Surgery. Edited by W. S. Christopher, M.D., John Ridlon, A.M., M.D., and Samuel J. Walker, A.B., M.D. July, 1902. Cloth. Pp. 231. Price, $1.50. Chicago: The Year Book Publishers. 1902.

BIOLOGIC SCIENCE. Vital Force the Only Power and Active Principle That Can Operate the Living Human Organism. Thought Exercise for the Nineteenth Century. A Criticism on the Teachings of Prof. Rudolph Virchow of the University of Berlin, and Prof. Jacques Loeb of the University of Chicago. By W. R. Dunham, M.D. Paper. Pp. 50. Keene, N. H.: Published by the Author. 1902.

PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. A Series of Eighty Plates, Comprising More Than One Hundred Illustrations, with Descriptive Text and a Treatise on Cutaneous Therapeutics. By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, N. Y. Part XIV. Price, $1.50. Philadelphia and London: J. B. Lippincott Co. 1901.

APPLIED SURGICAL ANATOMY Regionally Presented for the Use of Students and Practitioners of Medicine. By George Woolsey, A. B., M.D., Professor of Anatomy and Clinical Surgery in the Cornell University Medical College. With 125 Illustrations, Mostly Colored. Cloth. Pp. 521. Price, $5.00. New York and Philadelphia: Lea Brothers & Co. 1902.

REPORT ON OBSERVATIONS MADE ON THE CATTLE AT THE EXPERIMENTAL STATION AT OUTREMONT, P. Q. Recognized to Be Tuberculosis by the Tuberculin Test. By Prof. J. Georg Adami, M.A., M.D., and C. F. Martin, M.D. Paper. Pp. 32. Ottawa: Government Printing Bureau. 1899.

THE THEORY AND PRACTICE OF INFANT FEEDING, with Notes on [illegible] nry Dwight Chapin, A.M., M.D., Professor of [illegible] it the New York Post-Graduate Medical School [illegible] Numerous Illustrations. Cloth. Pp. 325. Price, $2.25. New York: Wm. Wood & Co. 1902.

REPORT OF THE MINISTER OF AGRICULTURE FOR THE DOMINION OF CANADA, for the Year Ended Oct. 31, 1901. Printed by Order of Parliament. Paper. Pp. 173. Ottawa: S. E. Dawson, Printer. 1902.

ANNUAL REPORT OF THE DEPARTMENT OF PUBLIC HEALTH OF SAN FRANCISCO for the Fiscal Year ending June 30, 1901. Paper. Pp. 271. San Francisco: The Hinton Printing Co. 1901.

TRANSACTIONS OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS. Vol. XIV. For the Year 1901. Cloth. Pp. 369. Philadelphia: Wm. J. Dornan. 1902.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Aug. 14 to 20, 1902, inclusive:

John D. Brooks, contract surgeon, member of a board at Fort

Yellowstone, Wyo., to examine officers of the Army for promotion.

George L. Cable, contract surgeon, former orders directing him to proceed from Fort Sam Houston to Eagle Pass, Tex., revoked.

Christopher C. Collins, lieutenant and asst.-surgeon, U. S. A., leave of absence extended seven days.

William H. Corbusier, major and surgeon, U. S. A., member of a board at Governor's Island, N. Y., to examine officers of the Army for promotion.

Elmer A. Dean, lieutenant and asst.-surgeon, U. S. A., from Columbus Arsenal, Tenn., on the expiration of his present leave of absence, to duty at Fort Strong, Mass.

James J. Edmonstone, captain and asst.-surgeon, U. S. Vols., having tendered his resignation, is honorably discharged from the service of the United States, to take effect Sept. 18, 1902; leave of absence granted to include Sept. 18, 1902.

Rudolph G. Ebert, major and surgeon, U. S. A., member of a board at Vancouver Barracks, Wash., to examine officers of the Army for promotion.

Harry L. Gilchrist, lieutenant and asst.-surgeon, U. S. A., member of a board at Vancouver Barracks, Wash., to examine officers of the Army for promotion.

Alfred C. Girard, colonel and assistant surgeon-general, in addition to his present duties, is detailed a member of the board appointed to meet at the Army Medical Museum, Washington, D. C., for the examination of candidates for admission into the Medical Corps of the Army.

J. W. Holland, contract surgeon, leave of absence for one month granted, to take effect Aug. 20, 1902.

Park Howell, lieutenant and asst.-surgeon, U. S. A., when relieved from duty at Fort Clark, Tex., by the arrival of Contract Surgeon C. S. Snyder, to report for duty at Camp Eagle Pass, Tex.

Harry M. James, contract surgeon, relieved from duty at Camp Thomas, Ga., to proceed to his home at New York City, N. Y., for annulment of contract.

Edgar A. Mearns, major and surgeon, U. S. A., member of a board at Fort Yellowstone, Wyo., to examine officers of the Army for promotion.

Robert H. Pierson, contract surgeon, former orders appointing him a member of a board at Governor's Island, N. Y., to examine officers of the Army for promotion are amended to read: Robert H. Pierson, lieutenant and asst.-surgeon, U. S. A.

Thomas L. Rhoads, lieutenant and asst.-surgeon, U. S. A., having arrived at San Francisco, Cal., will report for assignment in the Department of California.

Edmund D. Shortlidge, lieutenant and asst.-surgeon, U. S. A., is relieved from further duty in the Division of the Philippines and will proceed to San Francisco, Cal. On arrival he will report to the Adjutant-General of the Army for further orders.

George A. Skinner, captain and asst.-surgeon, U. S. A., now at Fort Harrison, Mont., will proceed to Fort Snelling, Minn., for duty at that post.

C. D. Snyder, contract surgeon now at Fort Niobrara, Neb., will proceed to Fort Clark, Tex., for duty at that post.

Henry D. Snyder, captain and asst.-surgeon, U. S. A., is relieved from duty as attending surgeon and examiner of recruits at New York City, N. Y., to take effect on the expiration of his present leave of absence; he will then report for duty at Plattsburg Barracks, N. Y.

William E. Vose, lieutenant and asst.-surgeon, U. S. A., having reported his arrival at San Francisco, will proceed to Columbia, Tenn., for duty at the Columbia Arsenal.

William J. Wakeman, major and surgeon, U. S. A., on being relieved from duty in New York City, will proceed to Fort McPherson, Ga., for duty at that post.

William L. Whittington, major and surgeon, U. S. Vols., leave of absence from the Division of the Philippines extended one month.

James S. Wilson, captain and asst.-surgeon, U. S. A., is honorably discharged by the Assistant Secretary of War, as major and surgeon, U. S. Vols., only to take effect Aug. 15, 1902; having reported his arrival at San Francisco, he will proceed to New York City, and relieve Major William J. Wakeman from temporary duty as attending surgeon and examiner of recruits in that city.

APPOINTMENTS, PROMOTIONS, CASUALTIES, ETC.,

in the Medical Department, recorded in the Adjutant-General's office between July 15 and Aug. 15, 1902:

Regular Army, Appointments.—To be assistant-surgeons with the rank of first lieutenant, to date from June 24, [illegible] Kirby-Smith of Tennessee, William H. Moncrief [illegible] L. Collins of Massachusetts, Charles F. Morse of [illegible] E. Lambert of Alabama, Haywood S. Hansell of [illegible] Gregory of Virginia, Clarence H. Connor of Iowa, Jay W. Grissinger of Pennsylvania, Will L. Pyles of the District of Columbia, Thomas Devereux of Minnesota, Robert H. Pierson of New York, Cary A. Snoddy of Tennessee, and Harry S. Purnell of Maryland.

Retirement.—Marshall W. Wood, major and surgeon, Aug. 12, 1902, for disability incident to the service.

Resignation.—Lieutenant William J. Calvert, asst.-surgeon, Aug. 9, 1902.

Volunteers, Appointments.—Captain Joseph C. Reifsnyder, asst.-surgeon, U. S. Vols., to be surgeon, with the rank of major, April 15, 1902; John P. Kelly of Florida, contract surgeon, to be asst.-surgeon, U. S. Vols., with the rank of captain, June 20, 1902.

Honorably Discharged.—Captain W. Hoepfner Winterberg, asst.-surgeon, July 31, 1902.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending August 23:

P. A. Surgeon E. O. Huntington, granted sick leave for three months.

Surgeon George A. Lung, ordered to the Bureau of Medicine and Surgery, Navy Department.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Aug. 21, 1902:

Surgeon Fairfax Irwin, granted leave of absence for one month from September 1.

Surgeon P. C. Kalloch, granted leave of absence for 3 days from August 27.

Surgeon A. H. Glennan, to report at Washington, D. C., for special temporary duty.

Surgeon S. D. Brooks, to assume temporary command of the Portland, Me., quarantine, during absence, on leave, of Surgeon P. C. Kalloch.

P. A. Surgeon S. B. Grubbs, granted leave of absence for fourteen days from August 19.

Asst.-Surgeon L. D. Fricks, relieved from duty at Boston, Mass., and directed to proceed to Savannah, Ga., quarantine, and assume temporary command during absence, on sick leave, of A. A. Surgeon W. J. Linley.

Asst.-Surgeon V. G. Heiser, to proceed to Immigration Depot, New York City, for special temporary duty.

Asst.-Surgeon T. D. Berry, granted fifteen days' extension of leave of absence, on account of sickness, from August 17.

Asst.-Surgeon J. W. Trask, relieved from duty at Detroit, Mich., and directed to proceed to Fort Stanton, N. M., and report to medical officer in command for duty and assignment to quarters.

A. A. Surgeon W. A. Kimmet, granted leave of absence for thirty days from August 10.

A. A. Surgeon W. J. O'Reilly, granted leave of absence for eight days from August 18.

Pharmacist and Chemist Henry Hahn, granted leave of absence for twelve days from August 18.

Senior Pharmacist Charles Miller, granted leave of absence for thirty days from September 9.

Senior Pharmacist J. V. LaGrange, granted leave of absence for thirty days from September 2.

Junior Pharmacist M. H. Watters, granted leave of absence for thirty days from August 18.

APPOINTMENT.

John William Trask of Michigan, commissioned (recess) as asst.-surgeon.

BOARDS CONVENED.

Board convened to meet at Southport, N. C., Aug. 21, 1902, for the physical examination of an officer of the Revenue Cutter Service. Detail for the Board: Surgeon John Godfrey, chairman; Asst.-Surgeon T. B. McClintic, recorder.

Board convened to meet at the U. S. Marine-Hospital, Stapleton, N. Y., Aug. 25, 1902, for the physical examination of officers of the Revenue Cutter Service. Detail for the Board: Surgeon Preston H. Bailhache, chairman; P. A. Surgeon A. C. Smith, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Aug. 23, 1902:

SMALLPOX—UNITED STATES.

California: San Francisco, Aug. 3-10, 2 cases.

Florida: Pensacola, Aug. 8-16, 4 cases.

Massachusetts: Boston, Aug. 8-16, 8 cases, 3 deaths; Brockton, Aug. 8-16, 1 case; Cambridge, Aug. 2-16, 5 cases, 3 deaths; Everett, Aug. 8-16, 1 case; Fitchburg, Aug. 8-16, 1 case; Somerville, Aug. 8-16, 1 case.

Michigan: Detroit, Aug. 8-16, 2 cases.

Missouri: St. Joseph, Aug. 2-16, 36 cases; St. Louis, Aug. 10-17, 2 cases

Montana: Butte, Aug. 10-17, 1 case.

Nebraska: Omaha, Aug. 8-16, 4 cases.

New Jersey: Aug. 8-16, Camden, 1 case; Newark, 3 cases, 3 deaths.

New York: New York, Aug. 8-16, 2 cases, 1 death.

Ohio: Cincinnati, Aug. 8-15, 1 case; Cleveland, Aug. 8-16, 58 cases, 8 deaths; Hamilton, Aug. 2-9, 1 case.

Pennsylvania: Aug. 8-16, Altoona, 1 death; Johnstown, 3 cases, 2 deaths; McKeesport, 1 death; Philadelphia, 1 case, 1 death.

Rhode Island: Providence, Aug. 8-16, 1 death.

South Carolina: Charleston, Aug. 8-16, 2 cases.

Utah: Salt Lake City, Aug. 8-16, 2 cases.

Wisconsin: Milwaukee, Aug. 8-16, 3 cases.

SMALLPOX—FOREIGN.

Austria: Prague, July 26-Aug. 2, 2 cases.

Barbadoes: July 29, 15 cases.

Belgium: Antwerp, July 18-25, 4 cases.

Great Britain: Liverpool, Aug. 2-9, 11 cases, 1 death; London, July 26-Aug. 2, 44 cases, 7 deaths.

India: Bombay, July 15-22, 3 deaths; Karachi, July 6-20, 1 case; Madras, July 12-18, 2 deaths.

Italy: Palermo, July 26-Aug. 2, 8 cases.

Japan: Formosa, May 1-31, 22 cases, 4 deaths.

Russia: Moscow, July 17-26, 5 cases, 3 deaths; Odessa, July 26-Aug. 2, 3 cases; St. Petersburg, July 17-26, 1 case.

Straits Settlements: Singapore, June 14-July 12, 2 deaths.

YELLOW FEVER.

Colombia: Panama, Aug. 4-11, 1 case, 1 death.

Mexico: Coatzacoalcos, Aug. 2-9, 9 cases, 1 death; Progreso, July 15-Aug. 9, 4 cases, 3 deaths.

CHOLERA.

China: Niuschwang, July 12-19, 66 deaths.

Egypt: Aboukoukas, Aug. 19, 78 cases, 38 deaths; Assiout Province, Aug. 19, serious; Cairo, Aug. 19, 3 cases; Charkieh, Aug. 19, 19 cases; Minieh, Aug. 19, 43 cases; Alexandria, Aug. 19, 2 cases.

India: Calcutta, July 12-19, 73 deaths; Karachi, July 6-20, 191 cases, 130 deaths.

Japan: Formosa, May 1-31, 7 cases, 4 deaths; Fukuoka Ken, to July 10, 101 cases, 56 deaths; Kobe, July 15, present; Nagasaki, July 1-19, 5 cases, 2 deaths; Mogi, to July 20, 23 cases, 16 deaths; Okayama, Aug. 9, present; Tokyo, July 9, 1 death.

Straits Settlements: Singapore, June 14-July 12, 170 deaths.

PLAGUE.

Australia: Brisbane, April 1-May 31, 45 cases, 17 deaths.

India: Bombay, July 15-22, 37 deaths; Calcutta, July 12-19, 19 deaths; Karachi, July 6-20, 74 cases, 60 deaths.

Japan: Formosa, May 1-31, 700 cases, 555 deaths.

Original Articles.

LINNÆUS AS A PHYSICIAN.[*]

LUDVIG HEKTOEN, M.D.
CHICAGO.

INTRODUCTION.

Among physician-scientists who achieved their greatest renown in some department of learning other than medicine Carl von Linné, better known as Carolus Linnæus, must be placed in the front rank. This great naturalist made for himself a permanent name in medicine also, but the extent and significance of his work and interest in medicine seem to have been more or less overshadowed by the fundamental importance of his work in natural science, especially botany.

The principal sources of the information in this article have been Richard Pulteney's excellent work on the writings of Linnæus,[†] in which the medical writings also are fully considered, and Hjelt's special work concerning Linnæus as a physician,[‡] based upon personal study of the writings and correspondence of Linnæus and of the records in the archives of the University of Upsala. Both these books appear to give altogether thorough and sympathetic reviews of Linnæus' medical activity in its various aspects as teacher, investigator and writer.

OUTLINE OF THE CAREER OF LINNÆUS.

Born in 1707, Carl von Linné was destined by his father for holy orders, but showed such distaste for scholastic studies and such desires to ramble in search of plants and flowers that his father was urged to apprentice him to a tailor or shoemaker. Through the kind efforts of a physician Linnæus was encouraged in his study of plants and of physiology, and eventually admitted to the University of Lund with a testimonial of the following dubious import: "Youth at school might be compared to shrubs in a garden which may disappoint the gardener, but if transplanted into different soil they may prosper." It was hoped that in the university the conditions might be more propitious for his progress.

As a student Linnæus assisted in private practice. At that time there was no real clinical instruction in Sweden, and it was customary for the young men to work under preceptors ("freqventera sjukstugan och lära av den svidandes egna mun"). When Linnæus came to Upsala in 1729 the medical faculty consisted of two professors and one adjunct. One professor taught pathology, dietetics, surgery, pharmacy; the other physic, chemistry, anatomy, physiology and botany, each constituting by himself a whole faculty. Olaf Rudbeck, the older, celebrated for his discoveries in the lymphatic system, had founded a botanic garden, but his successor, his son (1660-1740), though a good botanist, neglected botany for comparative philology and antiquarianism. In 1730 Linnæus had advanced so far in the esteem of his teachers that he was given a stipend and began to lecture on botany, with such success that intrigues were started against him and his docentship taken away. Advised by friends, Linnæus went to Harderwick, in Holland, where he obtained his degree in 1735, the title of his dissertation being "Hypothesis nova de febrium intermittentium causa." This thesis was founded principally on observations made in Sweden, where it probably was written. He sought, and after waiting eight days, gained admission to the great Boerhaave, then near the end of his illustrious career, but who helped him much in his botanical studies. At that time botany flourished in Holland, Boerhaave himself being a botanist, and Linnæus' love for botany kept him away from home and his future wife for three years longer. The work he did during this time exercised vast influence on the development of botany, being in reality the starting point of systematic botanical science.

He early became conspicuous in Holland and secured the regard of all that cultivated any branch of medical science, among them being Van Swieten and Lieberkühn. Linnæus reaped the greatest benefit from his close relationship with the illustrious Boerhaave, who showed the young Swedish scientist marked friendship and confidence. The following extract from Linnæus' diary—a curious and interesting document—describes their last meeting: "Before the time of Linnæus intending to leave Leyden, Boerhaave had been attacked with hydrops thoracis, and consequently with great difficulty of respiration; he had, therefore, given orders that no person should be admitted to see or speak to him, for he could not lie down in his bed, but was obliged constantly to sit up. Linnæus was the only person in whose favor exception was made, that he might see him and kiss the hand of his great instructor, to bid him a sorrowful adieu. The venerable invalid had still strength enough left to stretch out his hand, and (putting it to his lips and kissing it in return) to say: 'I have lived my time out, and my days are at an end. I have done everything that was in my power. May God protect thee, with whom this duty remains. What the world required of me it has got, but from thee it expects much more. Farewell, my dear Linnæus!' Tears prevented him from saying more, and, on Linnæus' return to his lodgings, he sent him an elegant copy of his Chemistry." And surely Linnæus may be placed by the side of Haller, Van Swieten, De Haen and others as a worthy pupil of a great master.

---

[‡] Otto E. A. Hjelt, Carl von Linné som Läkare och hans Betydelse för den medicinska Vetenskapen i Sverige. Helsingfors, 1877.

Greatly honored throughout Europe for his work in botany, so that Sauvages wrote, "the whole botanical world obeys you forever," and having received flattering offers to remain in Holland, and also from Oxford and Paris, Linnæus, in 1738, returned to Sweden and settled in Stockholm, where, after a desolate period of waiting for patients, he achieved his first success through treatment of gonorrhea. Always afterward he showed much interest in the treatment of gonorrhea and syphilis. He became naval physician and utilized his opportunities to study diseases and the actions of drugs. He also secured permission to make postmortems, heretofore but rarely granted, and Hjelt states that from this time the interest in pathologic anatomy increased in Sweden. In 1739 he married the choice of his heart after an engagement of several years; his practice increased rapidly, but he felt himself irresistibly drawn toward botany and natural science. He was offered a professorship in Göttingen, but in May, 1741, he received appointment as professor in Upsala in spite of a hot fight against him; the following year an adjustment with his colleague, Rosén, gave Linnæus botany and the botanical gardens, and for the succeeding thirty-six years the great botanist was continuously interested more or less in medical problems.

Thenceforward his life was a continuous course of prosperity. He was greatly honored. Botany occupied his special attention in spring and summer; in the autumn and winter months he gave the more purely medical lectures. He gathered about him a larger circle of students and listeners than any one either before or after him has done; the number of students in the university rose from five hundred to fifteen hundred, and he "shifted the scientific center of gravity to a small town in Sweden." Students flocked to hear him from Finland, Norway, Denmark, Germany, Russia, England, and even from America. Adam Kuhn of Philadelphia spent the years 1763-1765 in Upsala as student under Linnæus, who regarded him with special favor. Kuhn, in 1768, became the professor of materia medica and botany in the College of Philadelphia, where he gave lectures on materia medica for twenty-one years. When the College of Philadelphia, in 1791, united with the University of the State of Pennsylvania to form the University of Pennsylvania, Dr. Kuhn became professor of theory and practice of medicine, continuing as such for six years.

As a general result of Linnæus' influence, the study of the natural sciences received a mighty stimulus in the universities where logical disputations and metaphysical speculations too long had prevailed to the exclusion of science. The culture of natural science in Sweden was carried to a higher standard than elsewhere in Europe, but his pupils rapidly extended the doctrines and celebrity of their master, and before long numerous public institutions were established elsewhere also for the express cultivation of natural sciences. Linnæus emphasized eloquently the relations and importance of the study of natural history to the welfare of the people, and was ever striving to enlist the interests of the great in behalf of this study and to draw the youth of the land into its paths. In this respect there is great similarity between Linnæus and Pasteur; for Pasteur was irresistibly drawn toward scientific problems connected with industries of large economic importance. Linnæus found special delight in the study of natural science, which he regarded as "one of the richest and most permanent sources of pleasure which the kindness of providence has opened to the human mind." In his labor to arrange anew the history of the productions of nature "he found biology a chaos and left it a cosmos."

LINNÆUS' RELATIONS TO MEDICINE IN GENERAL.

Linnæus was deeply interested in the development of medicine in all its phases. He urged its establishment upon a rational basis of theory and observation. Exact observations of nature and logical grouping of the results are essential for progress, philosophical theory being the key to the explanation of practical observations, which in turn test the theory. While empirical medicine employs curative methods, the mode of action of which it can not explain, rational medicine endeavors to discover the laws, mechanical and otherwise, that govern structure and function, and to re-establish the conditions that are disturbed by disease. Weak hypotheses and prejudiced notions retard medicine as well as other sciences; if medicine is to develop, it, like other sciences, must employ experimental methods. He recognized and expressed clearly that rational medicine to a large extent is the result of co-ordination of anatomic, physiologic, botanic, chemical and mechanical truths. Hospitals and botanic gardens are necessary for the study of the nature and treatment of diseases. In fatal cases the internal organs should be examined in the end that the causes of disease may be understood and perhaps prevented or modified. He suggests that in many diseases the arrest of increased activity of the morbific cause may be all that can be attained.

Linnæus' interest in the methods of medical education proved of great importance to the study of medicine in Sweden. The course of instruction in the University of Upsala was modified and improved; the requirements for final examinations were raised and their character materially improved. Practical and public examinations in the hospital were introduced. Linnæus' lectures were characterized by clearness, conciseness, ingenuity of classification and direct bearing on practice, and the attendance became very large. Botany was not permitted to crowd out his interest in practical medicine in the widest sense. He wrote popular articles of medical nature, furnished material for almanacs and did much to disseminate useful advice and information. He aided veterinary medicine and helped it to secure recognition in his country. His writings in regard to alcohol unquestionably had some influence in checking the abuse of this substance. It was Linnæus' greatest pleasure to teach the results of his observations and to spread knowledge broadcast. Instruction was his most enjoyable occupation, and he regarded the creation of desire for and pleasure in study as the most important duty of university teachers. He did not hesitate to become the popular exponent of scientific observations, and as such we know he was instructive and inspiring.

THE MEDICAL PHILOSOPHY OF LINNÆUS AND HIS PRINCIPAL MEDICAL WRITINGS.

An interesting phase of Linnæus' work is the extensive correspondence he carried on with learned men and other persons all over the world. Perhaps the most noteworthy correspondence is that with François Boissier de la Croix Sauvages (1706-1767), professor in the medical school of Montpellier; between these two there was carried on a constant and frequent epistolatory exchange of ideas and observations without personal acquaintance. After Boerhaave, Sauvages undoubtedly exercised the greatest influence upon Linnæus' relation to and interest in medicine. Sauvages in 1731 published a work entitled "Nouvelles Classes des Maladies," which became Linnæus' guide in his lectures on nosology. In this work Sauvages, who also had a first love for botany, made the first attempt to arrange diseases into classes and species as recommended by Sydenham and Baglivi for medicine. The system and order in Sauvages' work at once appealed to Linnæus, in whom arrangement was a passion and classification a delight. Later, when Sauvages in 1760 published his great work entitled "Nosologia methodica sistens morborum classes juxta Sydenhami mentem et botanicorum ordinem," Linnæus at once introduced it as a text-book for his students. And Linnæus follows Sauvages closely[*] in his own work on "Genera Morborum" (1763), in which the diseases are classified into orders, classes and species. The system is largely symptomatologic. Acute inflammations are referred to fevers and divided into membranous and parenchymatous. Especially the group of Morbi dolorosi contains many single symptoms listed as distinct diseases. The group of Deformes and Vitia which comprise cutaneous affections and tumors, etc., represent definite anatomic forms. Naturally the system corresponds closely with the views prevalent among medical men at that time. There was then no real knowledge of the finer structure of the human body, the relation of diseases to anatomic changes were not understood thoroughly, symptomatology was the phase most actively investigated, and a large fund of therapeutic experience had been gathered. Morgagni's fundamental work in special pathologic anatomy, "De sedibus et causis morborum," did not appear until 1762. While Linnæus clearly recognized the importance of pathologic anatomy—he himself made postmortems while in Stockholm, and he subsequently urged their importance—yet his notions of general pathology were governed largely by his views concerning the action and nature of drugs.

MORBI.

Febriles (e sanguine in medullam)			Exantematici. Critici. Phlogistici.
Temperati	Nervini	Sensationis	Dolorosi.
		Judicii	Mentales.
		Motus	Quietales. Motorii.
	Fluidi	Secretionis	Suppressorii. Evacuatorii.
	Solidi	Interni	Deformes.
		Externi	Vitia.

Exanthematici	Febris cum efforescentia cutis maculata.
Critici	Febris cum urinae hypostasi lateritia.
Phlogistici	Febris cum pulso duro, dolore topico.
Dolorosi	Doloris sensatio.
Mentales	Judicii aberratio.
Quietales	Motus involuntarius.
Motorii	Motos abolitio.
Suppressorii	Meatum impeditio.
Evacuatorii	Fluidorum evacuatio.
Deformes	Solidorum facies mutata.
Vitia	Externa palpabilia.

Linnæus' philosophy of disease is based on the fundamental conception that the human body consists of cortical and medullary (nervous) substances; it is like a woven cloth of double threads, the nerves constituting the warp and enclosing various fibers and fluids, the weft. The medullary substance is of maternal origin and it is the first formed. Further, it is the seat of feeling and motion and the fluid and solid parts arise under its influence. The medullary part in turn is nourished by the finest materials in the cortical parts and by electricity taken in through the lungs from the air. Now, it is disturbance in the normal relations of these parts that cause disease. In fevers, for instance, the fluid cortical part is profoundly altered by acidifying (ab acido seri sanguinis) or decomposing substances that enter the body (a putrido cruoris sanguinis), the fever being critical in the first place and phlogistic in the second. Exanthematous fevers, on the other hand, perhaps depend on living contagium (ab exanthematibus vivis contagiosis). Every inflammation is accompanied by pain because the fibers are stretched to the point of breaking. In order to cure disease the condition of the fluid or solid parts must be changed to the opposite of that under which disease developed. Now, the power of medicines to produce such alterations may be recognized by their taste and smell, and the most important are obtained from plants of opposite smell and taste (sapida and olida). This theory of contraries is the leading thought of all of Linnæus' medical writings, and it constitutes the basis for his classification of materia medica. As seen from the subjacent table, he conceived that there were five kinds of taste and smell, each with its contrary, corresponding to five different pathologic conditions in the two constituent parts of the body. "Linné was the first who saw that nature is balanced by contraries, and acted upon numero quinario." He held smell to be due to motion in the nerves. The idea that the nervous system is distinct and separate from the rest of the body seems to have become necessary in order to arrange medicines in certain large groups because the odoriferous and volatile substances appeared to act directly upon the brain and nerves.

I. SAPIDA.

Agunt in corticale vitale:

	In Fluida.	In Solida.	
1. Aquosa	Mundificantia, Absorbentia.	Humectantia, Exsicantia,	Sicca.
2. Acida	Rifrigerantia. Balsamica.	Attenuantia. Tonica,	Amara.
3. Dulcia	Edulcorantia, Incidentia,	Impinguntia, Corrodentia.	Acria.
4. Viscosa	Inviscantia, Penetrantia,	Lubricantia, Abstergentia,	Salsa.
5. Pinguia	Obtundentia. Inspissantia.	Emollientia, Adstringentia.	Stiptica.

II. OLIDA.

Agunt in medullare animatum:

Sensum	Excitant	Aromatica	Sopiunt	Virosa
Motum	Spasticant	Argastica	Evacuant	Nauseosa
Judicium	Acuunt	Sprirituosa	Confundunt	Tetra
Libidinem	Provocant	Ambrosiaca	Suffocant	Airsina

Linnæus' pathology appears to be a compromise between the iatrochemic school—which taught that health depended upon the proper chemical relations of the fluids of the body—and iatromechanic or iatromathematic school—which explained disease according to the laws of mechanics and mathematics applied to the human body. While distinctly influenced by Boerhaave's fibrillar pathology, which sought explanations for disease in the tension and relaxation of fibers (fibrum strictum et laxum), which are constituent parts of the body, Linnæus carried this idea much further into details and sought also for corresponding conditions in the fluids. Accordingly, the fibers may be not merely tense or lax, but (a) moist, dry; (b) friable, tough; (c) fat, slender; (d) thick, thin; (e) flexible, stiff. As more or less corresponding conditions in the humors, including the blood, which are the real sources of solid fibers, he enumerates: (a) thin, thick; (b) acid, phlogistic; (c) oily, acrid; (d) plethoric, deficient; (e) glutinous, muriatic. The inter-relations between the fibers and the fluids are well expressed in the following sentence: "Qualis chylus, talis sanguis, qualis sanguis, tales fibræ, quales fibræ, tales oriuntur morbi." A fundamental idea seems to have been that equilibrium in nature depends on a constant struggle between opposites. "The human body may be considered as a balance, and when it equilibrates we feel well, but so soon as any overweight appears on either side, then we are sick." His principle of "contrariorum e contrarius curatio" is a further therapeutic application of this theory.

---

[*] Linnæus has 11 classes, 37 orders, 325 species. Sauvages, 10 classes, 44 orders, 314 species.

Materia medica was Linnæus' favorite branch in medicine. This naturally was due to the close relationship between pharmacology and botany. In those days botanists generally made incursions into medicine, and it undoubtedly was a source of much satisfaction to Linnæus that he could blend with his teaching of botany the practical part arising out of it, namely, materia medica. We know that he strove hard to introduce indigenous drugs into materia medica and to establish the cultivation of medicinal and other useful plants. He published a highly estimated Materia Medica (1749), which appeared in several editions in Germany. This work is regarded as his most important. The great A. von Haller calls it "commodissimum praelectionibus compendium, inter optima auctoris," and Gronovius and Royen added their compliments. For a long time it remained as a model for other authors. The pharmaceutical plants were arranged according to his botanical system and a careful description given of those drugs used in medicine with a brief statement of their therapeutic value. He endeavored to include only useful drugs and warned strongly against complex formulæ. The empirical classification was abandoned in favor of one based on the general theory that "sapida in fibras, olida in nervos agunt." The chief merit of the work is that by bringing some degree of order and system into this branch he laid the foundation for the scientific study and development of materia medica. He was instrumental in introducing into medicine quassia, solanum, dulcamara. and many other substances. Hjelt lays much stress upon Linnæus' effort to establish the nature of poisons which, he urged, give us the best medicines if rightly used.

Another noteworthy book is his "Clavis Medicinæ," which contains his fundamental pathologico-therapeutic theories in the most concentrated form. Perhaps this is the most remarkable of all his works because it is a definite attempt to construct a comprehensive medical doctrine upon the basis of certain theoretical conceptions. It certainly is a striking example of Linnæus' ability to co-ordinate and arrange scientific facts of various kinds under one leading idea. Couched in a more or less aphoristic language, it makes rather difficult reading. It is dedicated to Sigfr. Albinus, Anatomico summo, Alb. von Haller, Physiologico summo, Gerardo Van Swieten, Observatori summo, Franc. de Sauvages, Pathologo summo, Nicol v. Rosenstein, Therapeutico summo.

LINNÆUS' DIETETICS AND HYGIENE.

Linnæus was interested especially in dietetics and hygiene, and his lectures upon this topic were largely attended, and served to create marked professional and popular interest in hygiene, which thus got an early start in Sweden. He mentions six principal requisites for natural life, namely, fresh air, bodily movement, sleep, food, excretions and affections. He attributes hysteria and other morbid conditions among the rich to sedentary life. He explains the effects of air, exercise, etc., according to his general pathologic principles, as is further shown in this table from his "Clavis Medicinæ."

	FLUIDA.	SOLIDA.		
1. Excreta	Densa,	Torrida.		
	Tenuia,	Humida,	Retenta	2.
3. Motio	Phlogistica,	Tenacia,		
	Acidula,	Tenera,	Qvis	4.
5. Vigiliæ	Acria,	Macra,		
	Oleosa,	Pinguia,	Somnus	6.
7. Fames	Pauperata,	Gracilia,		
	Plethorica,	Turgida,	Cibus	8.
9. Frigus	Muriatica,	Rigidia.		
	Glutinosa.	Fluxa,	Calor	10.

The application of his general pathologic and therapeutic theories to hygiene is illustrated further by the following statements: Atmosphere influences the body through heat and cold. Cold renders the fibers stiff and the fluids more salty, leading to crystallization and stone formation, while warmth relaxes the fibers and promotes the formation of glutinous material. The softer the fibers the greater the viscidity, the opposite of salty. Motion makes the fluids active, the fibers tenacious, and as the fluids are distributed the parts come closely together. Rest leads to the production of acid and renders the fibers brittle. Sleep leads to fat in the solid parts and makes the fluids oily; hunger and waking makes the fibers thin and the fluids sharp, hence the best remedy for fat is waking. Excessive evacuations render the fluids thicker and fibers dry, bodily enfeeblement and emaciation resulting, while retention renders the solid parts moist and the fluids thin.

LINNÆUS' ETIOLOGIC THEORIES.

Linnæus paid especial attention to the question of etiology of disease. He regarded the cause as of fundamental significance in determining the kind of disease in a given case. Like the old physicians, he divided causes into proximal and remote, and according to his theory the proximal cause lay in changed tension of the solid parts or in altered mixture of the fluids, while the remote causes might be found in diet, age, bodily constitution, or in contagion.

Perhaps the most remarkable of Linnæus' various medical theories is the one concerning "exanthemata viva," or that contagious diseases depend upon the entrance of small living animals into the body. This assumption he regards as fully warranted, both in analogy and experience. Of such diseases he mentions scabies, epidemic dysentery (scabies intestinorum interna), pertussis, smallpox, pest; later leprosy, phthisis pulmonum and the malarial fevers were added to this category. While the small animals Linnæus had in mind had not yet been seen or described, he saw in the manner of the spread of infectious diseases a remarkable similarity to the mode of reproduction and increase of many animals, especially insects. The smaller an animal the more numerous and rapid its progeny, hence it is not difficult to conceive that some of these minute organisms by their excessively rapid multiplication may in a short time totally fill, as it were, the whole human body. As an illustration of this fact he cites the inoculation of smallpox, in which the quantity of pus used is of no import in securing the development of good pustules. That the contagious element is destroyed by cold, but multiplies in warmth is cited as another evidence of the parasitic origin of contagious diseases. Ustilago is cited as analogous to the contagious element. The drugs that destroy insects of various kinds—musk, camphor, mercurials, sulphur, etc.—were useful also in contagious diseases.

Linnæus always felt much interest in intermittent fever, which was endemic about Upsala at the time of his first arrival, and which formed the subject of his inaugural dissertation in Holland in 1735. He himself became a sufferer from this disease at the end of his sojourn in Holland. In Sweden intermittent fever occurred in clayey districts, and Linnæus first advanced the notion that particles of clay dissolved in water entered the blood and by arrest in the finer vessels interfered with cutaneous transportation. Later this theory of waterborne malaria was modified very much, and the disease was attributed to absorption by the skin of foul particles in the air, namely, miasms from quiescent waters, closed cellars, graves, decomposing animal and vegetable materials. Air, he urged, must contain some form of acid because vegetable and animal tissues and fluids become sour under its influence. Now, is it not possible that intermittent fever is caused by a coagulation of the serous part of the blood under the influence of "animalcula infinite parva" in the atmosphere which carry this acidifying substance. In further support of this theory he mentions the endemic occurrence of the disease in moist places with clayey soil and foggy atmosphere; the frequency with which it affects persons living on the ground floor or in cold, foggy places; the sour sweats of malarial patients, and the fact that bitter drugs, such as cinchona, which generally diminish acidity in the body, are the most useful in malarial diseases. Consumption, he believed, was caused by the inhalation of fine particles in the air which is permeated by minute floating substances of diverse kinds; this he illustrated by referring to the frequency of "tussis calculosa" among the stone-cutters in Orsa, Dalarne. He frequently makes mention of the contagiousness of tuberculosis. As an especially efficient treatment of incipient tuberculosis horseback riding is urged.

MISCELLANEOUS INVESTIGATIONS AND OBSERVATIONS.

In 1746-47 and 1754-55 he was engaged especially in studying a peculiar disease then appearing in the southern parts of Sweden (dragsjukan). His observations were summarized as follows: The disease attacks only the lower classes, but children never; it occurs only in the autumn and may show itself in domestic animals also; it lasts for two or three months, generally attacking several persons in the same household, but nevertheless it is not contagious. He concluded that the disease, which we now know as ergotism, is due to the use of freshly gathered corn; and as it occurred mostly after wet summers, when weeds abounded, he assigned the real cause to the weed predominating in the fields, namely, *Raphanus raphanistum* (jointed charloch or black radish), and suggested the name raphania. The disease was known under this term until the correct name arose from a more exact knowledge of its etiology.

Much of Linnæus' work is contained in dissertations by his pupils and many of them were enlarged transcriptions of lectures. A collection was made in a series of ten volumes,* of which seven are by Linnæus and three by Schreber and Erlangen. Pulteney gives an abstract of those by Linnæus' students.

Linnæus emphasized much the diagnostic and prognostic importance of the pulse. Actual knowledge of circulatory diseases seems to have been well advanced at that time, because we find he attributes irregular pulse to any of the following conditions: inflammation of the heart; dilatation of its muscle; aneurisms; tumors, polypi and abscesses of the heart; inflammation of the valves; obliteration of the pericardial cavity and other lesions of the pericardium; irregular action of the cardiac nerves. Further, it may depend on paralysis or spasm of the vessels, inflammatory stasis, ossification of the arteries, aneurisms and polypoid concretions. Finally, the cause may be in the blood itself.

It is of much interest to note that Linnæus suggested that fibrinous polypi within the vessels may be loosened and cause death from sudden suffocation. In other words, he recognized fairly well the mechanism of pulmonary embolism.

Linnæus distinguished correctly between cerebral hemorrhage and congestion. His description of hemicrania is excellent, being himself a sufferer from this affection. In 1742 he described well a typical case of aphasia under the title of "Failure to remember substantives, especially names" (Glömska af alla substantiva och isynnerhet namn). Matthew Baillie described aphasia first in English, and that was in 1806.

His study of the gadfly of the reindeer—Œstrus tarandi—during a journey of scientific exploration into Lapland while still a youth, is an excellent example of power of observation and of accurate and decisive description. In the first place the fly is described accurately, as is the method of disposition of the eggs on the skin by means of the tail. Then he shows that the gnats penetrate the skin at a time when the horns are in the velvet and so soft that the pests can not be driven away, the entire series of events as well as the intricate mechanisms brought into play being ascribed to the ingenious arrangement of an all-wise Creator. Even then he studied carefully sickness among men and animals.

Rosén and Linnæus made many important observations concerning parasitic worms; among those described is Tenia solium (Linné, 1756). He taught that tenia had no head and that it might grow ad infinitum.

CONCLUSIONS.

In terminating this fragmentary sketch of a small part of the work of Linnæus it seems to me that he is fully entitled to a place among the founders of the scientific school of medicine whose object it is to understand the nature of disease and to find and remove the causes of disease. The underlying principles, the scope and the results of his teachings and his labors entitle him to this distinction. At the same time as his predominating influence on the study of natural science in general, both directly, especially in Sweden, and indirectly advanced the scientific study of medicine, he himself and his pupils made distinct and permanent additions to our knowledge of diseases. He fully recognized and urged the importance of theoretic investigation in medicine, unprejudiced observation at the bedside, anatomical inquiry and rational therapy. Finally, he saw glimpses of great etiologic truths in regard to infectious diseases at a time when the great and populous microscopic world was indeed a "mundus invisibilis."

APPENDIX.

Linnæus' one foible according to the standards of today was love of fame and this frailty is freely exposed in his diary, the part of which concerning medicine is transcribed as translated from the Swedish manuscript in Pulteney's work, second edition, edited by Maton:

> Linnæus practiced physic at Stockholm from 1739 to 1741; he was physician to the great naval hospital there, and had, besides, as much practice as all the other physicians collectively; but, on being made Professor, he relinquished the whole of it, because either that or his duties as a Professor must otherwise have been neglected. From this period, therefore, he attended only his friends and the poor.

---

* Amoenitates academicæ seu Dissertationes variæ Physicæ, Medicæ, Botanicæ, etc. G. Dubois, 1748.

Physiology derived from him an important discovery, namely, Generationem ambigenam. Harvey maintained that the rudimentum futuri fœtus lies in ovi puncto saliente; Leeuenhoek, that it lies in genituræ verminulus spermaticis; Linné, on the other hand, that from the mother comes Carina Malpighii, rudimentum encephali, and from the father punctum saliens cordis, et inde totum corpus. This he proved by observations on hybrid animals, hybrid plants, etc. Thus, sense and temper, with tenaciousness of life, proceeded from the mother, but external appearance and habit, with strength of constitution, from the father. The Medulla spinalis would grow in infinitum if it were not confined by the spina dorsi tandem ossificata in pubertate; et a retropressione libido. The contrary happens in Tæniæ, and in vegetables which have no bone in their composition. Ossea crusta will grow infinitum, cæteris paribus. The object of respiration, he thought, is to extract the electric fluid from the air by the lungs and thus to transmit it to the medulla, becoming the spiritus animalis, as it were; and hence, that the chief office of the lungs is not to accelerate the motion of the blood. Some foreigner has considered this as an hypothesis only, but Linnæus as an axiom.

Pathology is a subject on which he corresponded more than thirty years with the learned Sauvages, above one hundred of whose letters are in his hands.

Genera Morborum have not been so clearly defined by any one; there is not a single word in them that is not useful; his work on this subject is an excellent compend for a tyro. He has divided fevers into three classes, after a method entirely his own: Exanthematicæ, typo scabici, ad exanthematibus vivis contagiosis; Criticæ, typo rheumatis (Fluss), ab acido seri sanguinis; Phlogisticæ, typo inflammatorio, a putrido cruoris sanguinis.

He was the first to explain that Tænia had no head and grows infinitum, and also that fragments of this creature sprout again.

That Lepra is caused by a species of Gordius, found principally in herrings, has since been confirmed by the Norwegians.

To show that Raphania is occasioned by the Raphanistrum required his thorough acquaintance with natural history.

He maintained that Scorbutus is caused by culinary salt.

Diet nobody has treated of in a more solid and satisfactory manner, though he did not publish anything on the subject. His doctrines, like those of the later natural philosophers, are deduced from experience, and his system, like theirs, may therefore be called experimental. Everything was deduced from occurrences in common life, cited in their proper places as examples, on which account his auditors were never more numerous than when he lectured on this subject. Several persons took notes at these lectures, but all the notes I have seen are incorrect.

Pathology, the foundation of the whole medical art and of all medical theory, has been more improved by Linnæus, in his Clavus Medicinæ of eight pages (which is a masterpiece in its way and one of the greatest treasures in medicine) than by a hundred authors and books in folio.

The Mechanical Physicians, indeed, had shown that the action of the Sapida consists in relaxing or constringing, according to the nature of their taste; but neither the species saporis, nor their contraries were explained—much less the nature of the Olida. Linné was the first who saw that nature is balanced by contraries, and acted upon numero quinario. He saw that the Creator had given to animals two senses, viz., taste and smell.

That the Sapida act only on the fluids and solids, or on the fibers.

That the Odora act only on the brain and nerves.

He found that Vitia Corporea, as well in the fluids as the solids, are only five in number.

That the Vitia Encephali, vel Systematis Nervosi are likewise five; each with the same number of contraries.

He likewise found that the Sapida and Odora are also five, with as many contraries, and that the right indication results from a comparison of contraries with contraries. He proved this by examples. What can be stronger?

For this was required all the knowledge that Linnæus possessed of diet, natural history, medicine, materia medica. Few physicians had been conversant with all these branches together. Fortunate were those students who, before his time, could acquire this knowledge.

Not to mention that Linnæus was the first who said that all our principal medicines are poisons; that physicians ought not to condemn poisons, but to use them, as surgeons their knives, cautiously.

The Materia Medica likewise was in a confused state, and many articles were imperfectly known until Linnæus reformed it. He introduced the genus, specific difference, select synonyms, place of growth, cultivation; deduced their medicinal effects and uses from the impressions they produce on the organs of taste and smell, and, lastly, described the several compositions, all of which had been either confounded or superficially treated of before, but by Linnæus were distinctly explained in his materia medica.

He was the first person who determined Sarcocolla, Balsam of Tolu quassia. He introduced several new articles; revived the use of others which had been forgotten: Ophiorrhiza, Fungus Melitensis, Senega.

Dulcamara. Linnæus was the first who brought this plant into general use in Sweden. He cured Syphilis and Scorbutus with it.† Virgo scorbuto summa afflicta, quam omnis generis remedia frustra essent adhibita, ejusque gradus ad summum pervenisset, Medicus Razout, concilio Sauvagesii, eam perfecte curavit solo usu decocti Dulcamaræ, quod remedium Sauvages ab Illo. Linnæo acceperat. Dulcamaræ decocto multos syphiliticos curavit Sauvages hujus usu à Linnæo edoctus.

Sauvagesium paucis ante abitum annis lippum, ut vix legeret librum, curavit Linné infuso caryophyllorum, ut ipse in literis fatetur "tibi debeo oculos meos."

Ledum. He was the first person who taught that it was the chief specific against the whooping cough.

Moschus. He was the first who introduced it for the cure of contagious diseases, and as a preservative or expellens horum, ex principio febrium contagiosarum ab exanthematibus vivis—now common.

R. Britannicæ (Rumicis Aquatici radix) applied to ill-conditioned ulcers, he was first informed of from America, and by him it was communicated to Europeans.

D'Ailland's powder he asserted to be (Pulvis) Baccarum Rhamni.

Guy's powder against cancer Foliorum Acteææ.

INJECTION TREATMENT OF SYPHILIS BY MEANS OF A NEW MERCURIAL FORMULA.*

M. L. HEIDINGSFELD, Ph.B., M.D.
Professor of Dermatology and Syphilology, Laura Memorial Medical College; Clinical Lecturer on Dermatology, Miami Medical College; Dermatologist to the Presbyterian and Jewish Hospitals.
CINCINNATI, OHIO.

In 1853 Alex. Wood[1] of Edinburgh introduced hypodermic therapy. Mercurial injections were first administered by Charles Hunter and Barclay Hill,[2] two Englishmen, in 1856. Hebra[3] in 1864 made a vain effort to treat syphilis constitutionally by means of large injections of corrosive sublimate, and Scarenzio[4] one year later carried on more successful and prolonged investigations by means of calomel injections suspended in gummatous solutions. All the above mercurial investigations, on account of the severe painful reaction induced by their administration, were short-lived, and would have doubtless remained unnoted and obscure had not Lewin[5] aroused new and well-sustained interest in this now generally conceded important field of therapy, in 1868.

Mercury and mercury alone is the sheet anchor in the treatment of the earlier stages of syphilis. It matters

---

† Act. Paris, 1761, p. 53.

* Read before the Ohio State Medical Society, at Toledo, May 29, 1902.

not through what avenue the administration takes place, lungs, intestinal tract or skin, or in what particular form—metallic, protoiodid, biniodid, sublimate, yellow oxid, red oxid, calomel, salicylate, foramid, sozoidol, tannate, etc.—it is administered, it is the assimiliated mercury which is effective; each preparation, and each form of administration has its peculiar advantages and objections, and the method which presents the happiest combination of large dosage, easy tolerance, convenient administration, absolute control and excellence in clinical results, will readily appeal to be the most acceptable and preferable.

The inunction method is the oldest, and though eminently reliable, efficacious, and very generally employed, it has its serious objections. The rubbing of a dirty ointment over the entire body is uncleanly, courts comment and publicity, soils bed linen and under-garments, frequently induces an artificial dermatitis, is contra-indicated in hairy individuals, precludes frequent bathing, and without the aid of an attendant is applied with difficulty. Inasmuch as mercury is volatile at ordinary temperatures, and more rapidly at body temperature, this form of administration is essentially an inhalation treatment, and as such, is strongly contra-indicated in hemoptysis and phthisis, an objection which applies to the inhalation treatment in every form, whether it be worn in sacks (Welander[6]), or as mercolint, (Blaschko[7]). Moreover the treatment is inexact.

The internal administration is a simple, convenient and popular form of treatment. It is eminently an inaccurate method because it is impossible to determine how little or how much mercury is assimilated. This is particularly true, if, as frequently happens, gastro-intestinal symptoms intervene, or if old, inspissated-gelatin-coated pills, or too strongly compressed tablets, are administered. The gastro-intestinal disturbance is often sufficient to distress the patient, impair digestion, induce loss of weight and to exert debilitating influences of considerable moment to this class of patients. What is probably the most serious of all objections, is the fact that the assimilated mercury, for the most part, is carried directly to the liver which, as we are beginning to believe, exerts a marked filtrating, altering and eliminating influence on toxic substances. This form of treatment also permits the patient to continue indefinitely, discontinue, or renew, treatment, in accordance with his own volition, and removes him from the regulating attention and vigilance of the physician.

Other forms of treatment—vapor baths, water baths, wearing of mercurial cloth, sacks, etc.—though useful as adjuvants, have not as yet received the stamp of general approval of being sufficiently active and reliable to merit special consideration in this paper.

The method of injection, which has been employed as already stated since 1856, has at times received popular favor, and at times has fallen into disrepute, according to the conditions which on the one hand recommend it above all other methods, and on the other, render it more objectionable. If the objections, which are largely technical, can be overcome the features which commend this form of treatment are so pronounced as to render the method justly popular and ideal. White[20] as early as 1894, when the method was relatively in its infancy, and its technic imperfect, in a series of interrogations addressed to all the leading writers and teachers of syphilology, demonstrated that the method at that time had come into very general and popular favor, and elicited the expression of a satisfactory past and an hopeful future. To Lewin[8] belongs the credit of demonstrating that the injection treatment can be successfully employed in supplanting with desirable effect the other forms of constitutional treatment of syphilis, an observation promptly confirmed by Sigmund[9] and Zeissl.[10]

Lewin[11] demonstrated by means of a series of 14,000 cases that the duration of treatment was shortened from ten to four weeks, that recurrences diminished from 80 per cent. to 40 per cent., and that rapidity of action, exactness of dose and immunity from gastro-intestinal disturbances, aside from the numerous objections to other forms of treatment, strongly recommended the method of injection.

For the injection treatment, mercury in almost every form, sublimate, calomel, yellow oxid, salicylate, soziodol, foramid, metallic, bicyanid, glycocoll, aspargin, alanin thymolo-aceticum and in almost every combination, albuminates, peptonates, benzoates, suspensions in mucilage, oil of vaselin, olive oil, paraffin, oil of sweet almonds, etc., has been employed. A brief survey of this unusual large field of literature and a careful estimation of its results will serve to demonstrate that also in injection therapy, efficacy and success depend, largely if not solely, on tolerance, convenience and dosage.

That the injection method, by meeting certain requirements, possesses decided advantages over other forms of treatment, is evidenced by the innumerable attempts at substitution; that these requirements have not as yet been satisfactorily fulfilled, is evidenced by the fact that nearly all have been short-lived or their use limited to relatively few individuals, and that the other forms of administration still find a large and generous patronage.

This paper will not permit me to enter into the consideration of the non-success of the many remedies which have been employed and recommended for injection use. It will suffice to say that bichlorid, which has been received into most generous favor, proved too painful to be well tolerated, causing patients to involuntarily withdraw from treatment, often induced abscess formation and severe induration, and could be administered only in such small doses as to require almost daily visits, which is ordinarily too expensive and too time-consuming for the patient. Pain, abscess formation and induration militated against calomel and salicylate injections, and graver complications against intravenous injections. A preparation which meets the requirements more successfully, I believe, than any other, is the ol. cinereum, or gray-oil after the formula of Lang.[12]

℞.	Lanolini	3
	Chloroform q. s. ad solutionem	10
	Hydrargeri	6
	Conteratur usque ad perfectissimam extinctionem hydrargeri.	
	Ol. vaselini	3

This formula, with the following modifications, has been almost exclusively employed by me, in both clinical and private practice for almost a year with most gratifying results. The injection as originally prepared, according to Lang, I found to be somewhat irritating and difficult to preserve. The modified form is prepared* by using bidistilled mercury, the same that dentists use in preparing amalgams. Six grams of bidistilled mercury can be readily incorporated in the course of a few minutes with two grams of lanolin when rubbed together in a clean mortar, which dispenses with the use of chloroform, which is a decided irritant, and is not, I believe, completely eliminated in the ordinary process of preparation. This simple modification did not suffice in itself to render the preparation as unirritating as desirable, and substitutions for oil of vaselin were successively tried with oleic acid, liquid paraffin, castor oil, cotton-seed oil, olive oil, etc., before a preparation was found which successively combined stability with nonirritability. This ingredient proved to be liquid albolene, which not only held the constituents well suspended and rendered them unaffected by ordinary temperature changes, but made the preparation so fluid that it could readily be utilized for injection purposes, though the mercury was increased from 50 to even 75 per cent.

---

* Dentists exercise great care in the selection of a pure bidistilled metallic mercury for the preparation of silver alloy amalgams. The commercial metallic mercury obtainable from common sources will not form a satisfactory amalgam.

The following has proved to be an excellent working formula and can be readily prepared, with a proper regard for asepsis and cleanliness by an office girl of average intelligence.†

℞. Lanolini 2
Hydrargeri bidistil. 6
Conteratur usque ad perfect extinctionem hydrargeri.
Liq. albolene 2
Sig.: Inject one grain (.06) every three or four days.

This preparation can be readily drawn into a hypodermic syringe, the needle applied and successive doses measured off by means of the retaining screw until the syringe is exhausted. One additional syringeful can be held in reserve and in this manner the treatment of each individual patient requires but a few moments of time. The injections should be made preferably into the buttocks at their most prominent aspect, alternating from right to left with each successive injection.

It has been my rule to give an injection every fourth day, using a grain dose (which contains approximately one and one-third grains of metallic mercury), and continuing until fifteen injections have been administered, that is to say, at least twenty grains of metallic mercury. In many cases I increase the dose to almost two grains, according to the indications, without untoward results. By this method relatively ten times more mercury is administered with each injection than with the regulation 15 grains of the 1 per cent. bichlorid, foramid or succinamid solutions, and more than twice the amount in the regular injections of calomel, salicylate, thymolo-acetate, yellow oxid, etc.

In all cases where the patient showed no marked intolerance to the remedy and remained free from complications, the injections were made at regular four-day intervals, and in many cases with a slightly progressive increased dose. My personal experience had impressed me that there are no special indications for a progressive decreased dose, and a gradual prolongation of the intervals between successive injections, as strongly urged by Ullmann,[13] Lang,[14] et al., in order to prevent any accumulative action and a consequent unfavorable action in such resulting complications as ptyalism, mercurial nephritis, etc. Mercurial stomatitis was carefully avoided as far as practical by exercising great care of the teeth, but, when it did ensue, as it is frequently wont to occur in clinical practice, its course was apparently scarcely more severe or intractable than that resulting from other forms of treatment.

In recent infections the injections were instituted with the appearance of the roseola, in accordance with the well-sustained views of Düring,[15] Taylor,[16] Watrazewski;[17] three courses of fifteen injections are administered during the first year of infection, two courses the second, one the third, and one every two or three years thereafter.

A seven-eighths inch 22-gauge steel needle is employed, which insures that the injection is deposited deeply into the layer of subcutaneous fat; the injection is supplemented with a few moments of gentle massage. In the beginning the injections were made with a needle one and three-eighths inches in length, in order to insure insertion into the deep muscles; experience soon taught that these injections were unnecessarily painful and poorly tolerated. It is not my practice to remove the syringe from the needle after insertion, as recommended by Lesser,[18] in order to test hemorrhage, and in more than 2,000 injections which have been made to date I have yet to note the slightest symptoms of embolism in the form of syncope, cough, pain in chest, shortness of breath. (Watrazewski, Quincke, Ludstrom, Oedmansson, Blaschko, Epstein, etc.) The clogging of needles, an objection which has been raised against the use of insoluble preparations (Bayet),[19] does not attain to this particular preparation; one needle suffices for more than a hundred injections, and is weakened and destroyed by erosion before it becomes plugged.

During the past twelve months, out of a total experience embracing 240 cases of syphilis, the injection treatment, wherever practical, was exclusively used, so that more than 2,000 injections were administered. Cases that had not attained puberty or where esthetic objections were offered, were excluded. The method has been employed sufficiently long, and the number of cases and injections have been sufficiently large, I believe, to warrant the unqualified statement that the results, as regards tolerance, excellence of clinical results, absence of complications, convenience and general efficacy, have exceeded the most sanguine expectations. This opinion is also shared by those of my colleagues in whose hands I have placed the remedy, whose impartial, unprejudiced and unbiased judgment gives it much additional weight.

Pain over the site of the injection is seldom noted. If present, it is usually slight and manifests itself for the most part during the second 24 hours. Its slight and transient character when present is best evidenced by the fact that patients submit willingly to the treatment and seldom voluntarily withdraw from treatment, even though they belong to the clinical ambulatory class. Induration over the site of the injection is usually slight and often imperceptible. Exceptionally patients show an idiosyncrasy to such a degree that localized pain and induration become so severe as to indicate a change to some other form of treatment; these patients often acquire tolerance, especially with diminished dosage. A change to some other form of treatment became necessary because of pain and induration in eighteen cases, or in about 10 per cent. of the cases treated. Abscess formation occurred in a single case, and was induced by careless administration of the injection in the hands of a student in a clinical case; the needle entered obliquely and the contents were deposited subcutaneously.

Marked improvement was noted in all the cases; material gain in weight, rapid amelioration of symptoms, improvement in appetite, color and activity were evident. A few cases responded promptly to this form of treatment that failed signally with other forms, and others.

---

† In warm weather, some of this liquid albolene separates from the preparation, and floats freely on the surface, which gives the mercury a doubtful percentage. This can be easily remedied by the following modification in what may be conveniently termed the "summer" formula.

℞. Lanolini .... 1|0
Hydrargeri .... 4|0
Conteratur usque ad perf. extinctionem hydrargeri.
Liq. albolene .... 1|0
M. Inject one-half grain every three or four days. One-half grain by volume contains approximately one grain of mercury by weight.

t showed intolerance to internal medication or in-tions, readily tolerated the injections. A case of tiple cutaneous gummata, in a physician, following long-standing extragenital infection, responded nptly to six ill-tolerated injections, after inunctions, rnal administrations and potassium iodid in large s had failed to favorably influence the condition. ase of severe syphilis, associated with progressive matous infiltrations and destruction of tissue, yielded nptly and completely to one course of injections, and after other methods and large doses of potassium iodid failed to benefit. Clinical examples of this character could be multiplied almost indefinitely, but it will suffice to state that, in point of efficacy, the treatment embraces all that is desirable, and that patients experience marked improvement, not only during the treatment, but a state of well-being that persists for many months after the treatment is suspended. In the vast majority of cases the patients show the greatest tolerance; in a few, owing to inexplicable idiosyncrasy, the distress is severe enough to render the treatment uncomfortable or a change to some other form highly desirable if not imperative. Taken all in all, its greater tolerance and the absence of complications should give this formula the preference over other forms of injections, and with the improvement in these directions the other natural advantages which accrue to the injection treatment over the internal and inunction methods, should give it the high and important place in syphilitic therapy which my personal experience during the past twelve months leads me to firmly believe it justly and deservedly holds. It has not, however, reached as yet that high state of perfection which bids it to entirely supplant all other forms; both the internal and inunction methods will still play very important rôles, not only as separate forms, but also when combined with each other or with injections, in accordance with the special indications. Every modification which renders the injections more tolerable and, at the same time, removes the likelihood of complications, is a step nearer the goal, and, inasmuch as the obstacles leading thereto are almost purely technical, it seems not at all unlikely that this goal can and will be reached as soon as mercurial injections attain the same relative tolerance that iodin injections have recently attained in iodopin.

One word of caution should be sounded in the use of this preparation: It is best to begin the treatment with a minimum dose (¼ to ½ grain per injection) and to gradually increase to 1 grain or more, in accordance with the degree of tolerance manifested by the patient. Great care should be exercised that the technic is properly carried out, and that a syringe, provided with a retaining screw, is employed; the screw should be properly set to guard against an excessive dose. These features should be forcibly impressed because their inadvertence in the hands of a few colleagues has been followed by untoward results. In one unfortunate instance an injection was made into the calf of the leg, instead of utilizing the gluteal region.

To recapitulate, the success of syphilitic therapy depends on the amount of mercury assimilated by the body, no matter in what form or through what avenue it is administered. Inunctions are objectionable because they are uncleanly, court comment and publicity, entail inexact dosage and predispose to dermatitis. The internal treatment is inaccurate, predisposes to gastro-intestinal disturbances, emaciation, anemia and the assimilated mercury is subjected to the altering, filtering and eliminating action of the liver. The injection method dispenses with all the above objections and combines with rapidity of action, relative greater efficacy, shorter treatment, diminished recurrences. Its strongest objections, in all its various forms, have been intolerance (local, pain and induration), grave complications and small and too oft-repeated dosage, instability, difficult preparation and administration of the remedy. These objections have been in a measure relieved by the above modified formula of oleum cinereum.

TREATMENT OF TUBERCULAR PERITONITIS.

WITH THE REPORT OF A UNIQUE CASE.*

MILES F. PORTER, A.M., M.D.
Professor of Surgery and Clinical Surgery, Fort Wayne College of Medicine.
FORT WAYNE, IND.

The opinions advanced in this paper are based on a study of the literature of the subject and a personal experience in the operative treatment of twelve cases. The time and the occasion make it incumbent on me to express myself concisely. No attempt, therefore, is made to explain in detail the reasoning nor the observations on which the opinions are based.

VARIOUS CURATIVE AGENCIES.

All forms of tuberculous peritonitis have been known to recover under medical treatment alone. All recoveries from tuberculosis of the peritoneum which follow operation can not be said to be due to the operation. The percentage of cures following operation is probably not so high as one is led to believe by the statistics of operators. The mortality of operation *per se* is not underestimated.

Celiotomy has a decidedly curative effect. This effect is due, not to any single cause, but to several. There is good reason for believing that all the theories offered are founded upon facts, but no single theory will explain all the cures.

LIGHT AS A CURATIVE AGENT.

The importance of the curative effect of light and air are, I believe, underestimated by most authors. Generally speaking, the best results have followed those operations in which the peritoneum was freely exposed both to light and air. All forms of the disease have been cured by operation, although the ascitic form has yielded the best results and the ulcerating and caseating forms the worst. Other foci are benefited by operation, so that

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Dr. Robert Bell's Library

the existence of tubercular deposits, in the lung, for instance, adds another reason for operation in a given case, rather than against it.

OPERATIVE TECHNIC.

The operative technic in tubercular peritonitis should be such as to give the patient the benefit of as nearly all of the known curative agencies as is possible with the use of good judgment. The inoculation of a tuberculous peritoneum with putrefactive bacteria is a procedure too dangerous to be practical. Incision should be free; fluid, if present, completely removed; tubercular foci, if accessible and not too numerous, should be removed. Adhesions should not be disturbed save when necessary for the removal of tubercular deposits, fluid or the relief of bowel obstruction. An exception to this rule should be made in those cases in which the adhesions are easily separated and extensive enough to prevent free access of light and air. Drainage is dangerous and should not be used except in cases of mixed infection. Lavage with hot water is not injurious and may be beneficial. Chemical antiseptics should not be used save in mixed infections. The abdominal cavity should be freely exposed to light and air for several (ten to fifteen) minutes. I can conceive of no valid ection to the exposure of the cavity either to the r the ultra-violet rays of Finsen. I would ad- l of both of these agents, and am preparing to atter in the next case coming to me for treat- That actinic light will penetrate the human body seems proven, but there seems to be sufficient reason for believing that the efficiency both of the x-rays and actinic light, in the treatment of tubercular lesions, is much enhanced by exposure of the lesion to the direct influence of the rays.

There is good reason for believing that operative treatment along the lines indicated above, coupled with direct exposure of the abdominal cavity and contents to actinic light, or to the x-rays, will prove a better method of treatment for tubercular peritonitis than any other yet devised. In case the actinic light or the x-rays is not available, the cavity and contents should be freely exposed, for several minutes, to the strongest light that is available.

REPORT OF A UNIQUE CASE.

median line for a distance of three inches between the umbilicus and pubes and through this incision discovered for the first time the true nature of the trouble. The peritoneum forming the sac was studded with tubercles. The roof of the sac was formed by agglutinated intestines and stretched across the abdomen, about on a level with the iliac crests. The pelvic contents were healthy save that the peritoneum covering them was studded with tubercles. The cavity was emptied of fluid, wiped dry, the hernial sac excised and both wounds closed with catgut sutures, including the skin. The patient's recovery was uneventful and she is now (eleven months after the operation) enjoying apparently perfect health.

It is proper to note here that after leaving the hospital, she was treated by Dr. Drayer, her physician, for two months by abdominal inunctions of Credé's ointment and the internal administration of hypophosphites, and was given the full benefit of the sunshine and open air.

Thomson[16] has had three cases in male children in which there was tuberculosis of the patent vaginal process coexistent with general peritoneal tuberculosis. The cases were cured either by simple incision of the process or by excision of it. Gould also says Harold Stiles, Goldman and others have reported similar cases. I have not been able to find the reports of Stiles or Goldman. Jordan[75] reports a case of tuberculosis sicca of a large irreducible inguinal hernia. After an exploratory incision, the hernia became reducible, the patient's health improved and the thick masses found at the time of the operation largely disappeared, but a sinus which discharged thin pus still remained. Naumann[44] reports two cases of congenital hernia with peritoneal tuberculosis in which he withdrew the fluid through the hernial opening. Further details of Naumann's cases are not given in the abstract referred to and the original[76] article was not available when this was written.

These are all the cases similar to mine of which I could find the reports. It will be noted that mine is unique in that the hernia was acquired and consisted only of sac and fluid contents.

DISCUSSION.

Dr. Joseph Ransohoff, Cincinnati—It is very evident that no one method is going to be of advantage in all cases, and also that very many cases of so-called surgical tuberculosis get well under medical treatment. It is perhaps an inopportune time to discuss this subject, so far as the surgical aspects are concerned, but it seems that the time is not far distant when the *x*-ray will be enabled to make a surgical operation superfluous in some cases. In cases which have apparently gotten well and in which relapses made second operations necessary, where the *x*-ray had been used in the meantime, such a change had taken place in the tubercular nodules as to make one feel some remarkable good was accomplished by the *x*-ray. In two of my cases of ascites I did nothing but drain. Both recovered perfectly, and both young women are now in good health. One of these cases is of 7 years' standing. I did not go to the radical procedure of removing the tubes, although it has been said that it is just as well to do so, in order to prevent tubercular progeny. We have all seen tuberculosis of the male gland treated simply by incision and in whom subsequently the possibility of enjoying parentage was not interfered with. Are we justified in coming to the conclusion that a tubercular tube must be removed any more than a tubercular testicle should be? Conservatism is the order of the day in one and why not in the other. In these cases it has been my experience that the less the interference the better and we should not interfere unless we have to. The danger of postoperative generalization of the disease must not be overlooked.

Dr. A. E. Halsted, Chicago—My experience in the operative treatment of tubercular peritonitis is limited to eight cases. One of these cases demonstrates that operative treatment is not always successful, and that it is not, as is generally supposed, devoid of danger. This patient died as the immediate result of operation. A second case demonstrates that complete recovery is possible, even where there is extensive glandular involvement.

My opinion is that light and air have very little effect on this condition. It is difficult for me to see how such short exposure of the peritoneum to the air and light could affect materially well-developed tubercles. My experience in this disease leads me to believe that the good effect of the operation is due entirely to the reaction that follows the trauma to which the peritoneum is subjected. Gatti demonstrated in his experimental work on tuberculosis of the abdomen, that the disappearance of the tubercles and cicatrization which resulted after operations for tubercular peritonitis, was the result of the bactericidal action of the exudate that followed opening of the peritoneal cavity. He further found that this exudate which corresponded in its chemical properties to blood serum possessed a greater bactericidal action than does normal blood serum. From this, it is my opinion that the operation will be followed more frequently by cure if we resort to swabbing and irrigating the peritoneal cavity. I do not believe that any chemical substance that can be used with safety in the peritoneal cavity is of much value in the cure of peritoneal tuberculosis. Undoubtedly the good effects that have followed the use of iodoform are due to its action in producing traumatic peritonitis. As to the breaking up of adhesions, I have found that it can not be done with safety to the patient. In these cases, where the adhesions are very extensive, it is better to limit the operation to the opening of the peritoneal cavity to evacuating the fluid and swabbing the surface of the diseased membrane with salt solution. In cases where we have a number of circumscribed, sacculated exudates, I consider that each of these cavities should be opened and drained. I am not in favor of immediately closing the abdomen in these cases, but believe that considerable benefit follows drainage.

As to the etiology, we now know that by far the greatest number are from infection that spreads from the pleura, or lung, and that it is only in rare cases that the primary focus can be demonstrated in the tubes. We must also remember that where the tubes are found diseased that this condition may be secondary to the abdominal tuberculosis.

As to the prognosis after operative treatment, it may be said that the best results are to be had in those cases with the ascitic form of tuberculosis. In these, a definitive recovery may be expected in from 40 to 50 per cent. In the adhesive form, the prognosis is very much more unfavorable, only about 15 or 20 per cent. recovering after operation. In the ulcerative and suppurative form, operation is, in my opinion, practically useless. As to the value of removing the tubes in these cases, I believe that it will be difficult to determine in any case positively whether or not the tubes are the primary seat of disease. If for any reason we suspect they are, it would be only rational to remove the tubes at the time of operation.

I wish to report two cases that are of peculiar interest, inasmuch as one illustrates a complete cure, and another a fatal termination:

Case 1.—Miss D. Young woman, unmarried, aged 19, had up to two weeks before been well. At that time she noticed that the abdomen was larger than usual. This rapidly increased and was associated with indefinite abdominal pain and obstinate constipation. There was some dysuria and a decided diminution in the quantity of urine. On examination the abdomen was found considerably distended and there was free fluid in the abdominal cavity. The thorax was negative, as were the liver and pelvic organs. There was no definite abdominal tumor and the general appearance was fairly good. The skin was decidedly pigmented, so that it had a bronzed appearance which suggested Addison's disease. The sclera was icteric.

There was a slight puriform vaginal discharge which on examination showed no tubercle bacilli or gonococci. At the end of the week she was operated on.

A second examination before operation showed an area of dulness which extended from a point half-way between the ensiform cartilage and the umbilicus and pubis. This area was wider in the meso-gastrium than above and below, measuring at its widest part about four inches. On palpation there could be felt a distinct tumor mass, spindle-shaped in outline and giving the sensation of fluctuation. This was freely movable latterly, but appeared attached above and below. On each side of this dull area there was a tympanitic area on percussion, until the area of free abdominal fluid was reached. A diagnosis of abdominal tuberculosis was made by excluding other forms of ascites. There was no history of tuberculosis in the family.

Operation.—The abdomen was opened by a median incision, and a large quantity of straw-colored fluid escaped. The intestines were found adherent in many places; it was closely studded throughout its entire extent with small miliary tubercles. The bursa omentalis was rolled on itself and in its lumen was fluid. The lower end of the omental tube was attached to the anterior abdominal wall close to the pubis. No attempt was made to separate the inherent coils of intestine. The fluid was evacuated as completely as possible and then drained.

The patient's condition during the first twenty-four hours following operation was not materially changed; temperature normal, pulse rapid and mind clear. At the end of the first twenty-four hours she was suddenly attacked with severe epistaxis. This was controlled by plugging the nares. Within a few hours hemorrhages began from all the mucous membranes. At the same time large purpuric spots appeared on the chest and the extremities, which increased in size and number until the entire surface of the body was covered. Intermuscular hematoma also developed. The temperature rose to 100 F., pulse gradually became imperceptible and she died in coma thirty-six hours after the operation.

(Discussion continued on p. 624.)

FURTHER EXPERIENCES WITH A MODIFICATION IN THE OPERATIVE METHOD FOR INVETERATE RELAPSING AND ALL AGGRAVATED FORMS OF PES EQUINO-VARUS.*

A. F. JONAS, M.D.
Professor of Surgery in the Medical Department of Nebraska University; Surgeon to the Omaha (M. E.) Hospital, the Douglas County and Wise Memorial Hospitals; Chief Surgeon of the Union Pacific Railroad Company.
OMAHA.

Congenital deformities involving chiefly the mediotarsal joint come so frequently to our notice that they seem to have lost interest. Manipulations, brisement forcé, tenotomies and retentive appliances when carried out with judgment and patience in time tend to recovery in a large number of cases. When these corrected deformities pass from under the observation of the surgeon the results are designated as satisfactory, meaning by that, that the plantar surface rests squarely on the floor and that walking is accomplished, not perfectly, for there is still a slight limp, a slight toeing inwards, possibly a moderate rolling inwards of the entire extremity. The patient and friends are cautioned that relapse is possible and probable if corrective measures are at once abandoned. Your injunction, it is one thing to correct a deformity and an entirely different and more important matter to keep it corrected, is given with emphasis in the hope that it will be heeded. It is a well-known fact that individuals often tire of prolonged attention and care so needful to make permanent a certain result. Consequently, many cases recorded as cured return after a lapse of time, partly or completely relapsed. Often the deformity has become aggravated to an extreme degree, so that the outer and upper side of the foot is the surface bearing the superimposed weight, the plantar surface pointing inward and backward, presenting a well-known type known as inveterate and relapsed talipes equino-varus. Every surgeon is brought face to face with relapsed cases of his own, he sees more who have been in the hands of other surgeons. It is impossible to repress the desire for some method that promises greater certainty as to permanency. He has found that gradual corrective measures, or operative procedures that involve a long post-operative treatment are unsatisfactory, chiefly on account of indifference on the part of the patient or his attendants. Constant attention is necessary; retentive apparatus is early broken or is rapidly outgrown, requiring frequent renewal, creating an expense unwillingly borne. Unfortunately, the vast number of cases of foot deformity are found among the poor, who can ill afford the necessary appliances. They have not the means nor the time to devote to the proper attention demanded by such a case. The indications are plain. Some plan must be devised whereby a pes equino-varus may be corrected which is unattended by a prolonged after-treatment.

NATURE OF THE DEFORMITY UNDER CONSIDERATION.

The deformity that shall engage our attention for a few moments consists of a deviation inward and downward of that portion of the foot chiefly anterior to the medio-tarsal joint, causing the superincumbent weight to be borne on the outer and often the dorsal side of the foot, with a shortening of all the soft structures on the concave side of the deformity, consisting of the skin, superficial and deep fascia, fibers of the internal fasciculus of the plantar fascia, the adductor hallucis muscle, internal plantar nerve and artery, the tendon of the tibialis posticus and anticus, internal lateral and calcaneo-scaphoid ligaments. The soft structures on the outer or convex side of the deformity are elongated. The tarsal bones have become modified in accordance with their abnormal relations to each other.

HOW THE DEFORMITY MAY BE OVERCOME.

The indications to be met consist in elongating the shortened soft structures, replacing the bones, dividing and excising on the convex side of the deformity such hypertrophied and distorted osseous structures as interfere with complete replacement. Whether this is accomplished by force or by subcutaneous or open-cutting operation the tendency to recurrence must always be taken into account, therefore, over-correction has become the rule. And yet this over-correction has not always been sufficient to prevent recurrence. All operative and mechanical methods require repeated sittings, extending over a considerable period of time, making it irksome to the patient, and he frequently passes from observation before the cure is complete.

THE PHELPS OPERATION.

Phelps, in 1881, made the most radical departure from the then prevailing methods, by boldly cutting all the soft structures on the concave side of the deformity and then forcing the foot into a valgus position. His earlier efforts were followed by partial recurrence of the deformity owing to imperfect antisepsis.

When Schede made known his observations on healing under a moist blood-clot in bone cavities, its application found a place in the Phelps operation. The wound was covered with a silk protective, retaining a blood-clot under it, insuring a more rapid reparative process and a less degree of recurrence. Many modifications of the Phelps method have been undertaken, chiefly by Mr. Arbuthnot Lane, F. H. Kellock and Muirhead Little, with the aim to cover the large wound, and Dr. William Gardner sought to overcome the osseous defects by inserting between the scaphoid and astragalus a wedge of decalcified bone to fill the space resulting from correcting a severe varus deformity.

THE AUTHOR'S METHOD.

It was the writer's privilege to present to the Western Surgical and Gynecological Association at its Omaha meeting, a modification which has proven useful in the hands of several surgeons, in permitting immediate correction of the deformity and at the same time guarding against recurrence. The steps leading to the adoption of the plan were made after personal trials of various skin-flap operations, both pedunculated and free. They possessed the drawback of the liability to necrosis from inefficient blood supply, and yet integument was the only tissue that could cover the large gap in the Phelps operation. It was evident that if an attached flap with a broad pedicle could be produced that under all circumstances could contain a sufficient blood supply to insure its life, at the same time cover a greater part of the wound, more particularly the deeper part of the wound produced by the severed fascia, tendons, muscles and ligaments, we should make an advance toward more rapid repair and obviate to a large degree relapses.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

It was proposed to make a triangular flap, similar to that sometimes used in relieving Dupuytren's contraction of the hand, a V-shaped incision as advocated by Busch and others for cicatricial contractions after burns on the flexor sides of the extremities. An incision was made, beginning slightly below the margin of the plantar fascia on the inner side of the foot, at a point on a line directly below and anterior to the internal malleolus, extending forward and upward to a point on the first metatarsal bone and nearly to the metacarpo-phalangeal joint. A second incision was made, beginning at a point over the astragalo-scaphoid articulation, extending forward and slightly downward, joining the first incision near the meta-tarso phalangeal joint, forming a V. The incisions were deep so as to include all the subcutaneous structures, including the fat. This flap was dissected backward to the points where the incision began, producing a large triangular wound, making it possible to divide all the necessary structures under the guidance of the eye. All the soft structures were thus exposed. The inner fasciculus of the plantar fascia was divided diagonally. The diagonal division of the plantar fascia was done, so that after correction there should be left no defect between the divided ends, but that the points of the incised fascia should still lie in contact, thereby lessening the tendency to contraction. The remaining structures were then divided as directed by Phelps, until the astragalo-scaphoid capsule was reached. Instead of dividing this, another incision was made on the outer side of the foot over the head of the astragalus, extirpating first the bursa which is usually present, then the tendons and soft structures were pushed to one side and the neck of the bone was exposed. The neck of the bone was then cut with a chisel. The foot could then be pushed outward without separating the astragalo-scaphoid articulation, which nearly always occurs in the Phelps operation. Occasionally, in old and inveterate cases, it became necessary to make a cuneiform excision of the neck, and in several instances the neck and head of the astragalus were removed. The varus having been over-corrected and turned into a valgus, the equinus deformity was relieved by a subcutaneous division of the tendo Achillis. All hemorrhage was easily controlled with catgut ligatures and pressure. The triangular flap was then turned back; it covered the wound except at its anterior point. No sutures were employed. A perforated silk protective covered the wound. The outer wound over the astragalus was closed with catgut. An antiseptic dressing was applied and over this a retentive dressing of plaster of paris, beginning at the toes, extending upward above the knee, including one-third of the length of the thigh. The dressing was not disturbed under five weeks. The wounds were then completely healed.

ITS VALUE PROVEN BY EXPERIENCE.

Further experience with this method has demonstrated its usefulness. An increasing experience has given an increasing confidence. The triangular flap falls of its own weight over the defect left by the retreating severed soft structures, entirely preventing the shelving edges found in the original Phelps operation. The healing process is shortened on account of the smaller surface to be covered by the process of epidermization. The astragalo-scaphoid ligaments were not severed, avoiding an opening of this joint, consequently preventing the great gap between the articular surfaces, which is unavoidable in the combined radical cutting followed by forcible correction. It was found that the axis of the neck of the astragalus had deviated inward in old cases so that the articular surface of its head was inclined inward, offering a most stubborn resistance. No amount of force could overcome this. A transverse division of the neck with an osteotome in nearly all cases permitted a replacement of the anterior part of the foot with very little force and the astragalo-scaphoid joint was not opened. In several instances a cuneiform excision from the astragalus neck with a sharp, bone-cutting forceps was required for complete reduction. In a few very advanced cases the head of the astragalus had to be removed. In two instances the astragalus was so rotated that its superior articular surface was inclined outward to a degree that it rested in part against the fibula, necessitating a division of the internal lateral ligament, before the bone rested normally against the tibial articular cartilage.

The triangular flap, although at first employed for old and relapsing cases, is now used wherever force and subcutaneous tenotomies are inefficient, whether the cases are recent or old.

CONCLUSIONS.

In conclusion we may say that:

1. The triangular flap is indicated in cases of pronounced talipes equino-varus wherever an open operation is necessary to overcome the deformity which involves the medio-tarsal joint.
2. The astragalo-scaphoid ligaments and capsule must not be incised or torn.
3. When the division of the soft structures is not sufficient to overcome the varus deformity an incision over the head and neck of the astragalus must be made and the bursa extirpated.
4. The neck of the astragalus must be divided transversely with an osteotome. If this is not sufficient, then remove a wedge from the neck; if that fails, remove the head.
5. If the astragalus has rotated so that its superior articular surface is inclined outward, and a replacement is impossible, the internal lateral ligament must be divided, which can be done through the opening made by the triangular flap.
6. The best possible guarantee against relapse is to divide soft parts and bone, so that the foot falls into its natural position with little or no pressure.

The French System of Prophylaxis Against Tuberculosis.—Professor Phocas of Lille remarks that the sanatorium treatment of tuberculosis can be called the German system, and superabundant feeding the English system, while the seashore children's asylums can be called the French system of combating tuberculosis. The French have a number of well-equipped and well-managed seashore hospitals for children, and the aim is to send to them scrofulous and other sickly children and transform the predisposition to tuberculosis into sound health. The *Nord Méd.* of August 1 commences the publication of the annual report of the sanatorium at St-Pol-sur-Mer, in charge of Phocas, which shows how much can be accomplished in this line.

THE PREVENTION OF DEFORMITY.[*]

WISNER R. TOWNSEND, A.M., M.D.
NEW YORK CITY.

While the entire medical profession of this generation are earnestly striving to better the condition of the human race by the prevention of disease, it seems an opportune time also to enlist their efforts toward the prevention of the many deformities of the body which surgeons are called upon to treat. That great results have followed the establishment of proper quarantine regulations is admitted by all, and the wonderful change in the conditions of Havana and other Cuban cities since the American military surgeons have been placed in control of sanitary affairs, is a matter of sincere congratulation and the good effects will be far-reaching. In many other directions preventive medicine is attracting the attention of the entire world, and no subject is more thoroughly discussed to-day than the prevention of tuberculosis. While authorities may differ as to how the result can be best and most speedily accomplished, all agree that it must be done. On this last point there is no difference of opinion. But while medical men admit that deformities of the body will occur unless certain precautions are taken to prevent them, the vast majority of patients coming to the surgeon for the relief of deformity clearly state that nothing was ever done to prevent its occurrence. That this subject has not received the attention it deserves will be admitted by all.

The desire to prevent unnecessary suffering, to prevent deformity, to obviate the necessity of surgical operations and the wearing of apparatus should be the aim of every medical man who is called upon to treat a patient whose disease is of such a character that unless proper treatment is given, deformity will follow, yet most cases of infantile paralysis, chronic joint disease, burns and many other conditions are treated only with the idea of curing the diseased condition, and no attention is paid to the resulting deformity. From an experience in public work at the Hospital for the Relief of the Ruptured and Crippled in New York City and from private records, the writer believes that more than half the deformities seen could have been prevented, and the time will come when they will be, and the long list of operations for the correction of deformity following infantile paralysis, chronic joint disease, faulty decubitus in typhoid fever, rheumatism and other conditions, will no longer figure so prominently in the records of work done by the surgeon.

Practically all the deformities due to poliomyelitis or infantile paralysis can be prevented. "The original lesion does not primarily produce a deformity, but simply a loss of power in the muscle or muscles affected. The production of deformity is due to: 1, gravity; 2, the action of non-paralyzed muscles; 3, the arrested development and growth of all tissue in proximity to the muscles paralyzed; 4, the results of weight applied to the weakened structures; 5, all other causes."[1]

"The contractures may come on very slowly, and in the foot, after several years, there may only be a slight equinus, yet that equinus, by the patient's endeavor to walk flat on the foot, may be the cause of a most severe hyperextension at the knee and much subsequent trouble."[2] Thus we see one deformity causing another, and, had the first been prevented, the subsequent care of the patient would have been much simplified. Most of the deformities are of the lower extremities, because it is more often affected, and because the various causes that produce these results have better opportunity here than elsewhere, and some form of clubfoot is the condition needing treatment. The varieties of clubfoot are many, and the non-congenital are nearly all preventable by simple treatment and by a clear recognition of the fact that unless care is taken they will occur. Non-congenital clubfoot may be divided into: 1, simple acquired; 2, paralytic; 3, traumatic.

1. Simple acquired clubfoot includes all cases due to rachitis, rheumatism, chorea, hysteria, malaria, chronic ergotism, faulty positions in standing, tumors, weak ankles, relaxed ligaments, sprains, diseases affecting hip, knee, leg, foot or ankle, non-paralytic, as synovitis, arthritis, caries, necrosis, osteomyelitis, etc.
2. The paralytic includes all cases due to poliomyelitis anterior, hemiplegia, meningitis, myelitis, progressive muscular atrophy, spastic cerebral and spinal paralysis, compression myelitis, irritation of pyramidal tracts, syringomyelia, etc.
3. The traumatic includes all cases due to fractures, dislocations, injuries to skin, fascia, muscles or nerves, burns and cicatrices.

"In an analysis made in 1890 of 7,101 cases of clubfoot seen by different observers, 3,601, or over half, were non-congenital in character, showing the accuracy of the statement that fully half the deformities seen are preventable."[3] By manipulation, massage, light retentive dressings, of wood, paper, felt, leather, plaster of paris, silicate of soda, steel, etc., any portion of the body can be so kept that the various causes mentioned can not exert their harmful influence and deformity can be prevented and this is especially true of non-congenital clubfoot.

In chronic joint disease the proper treatment consists in the cure of the disease without deformity, but how often is this accomplished? "Osteitis of the knee, involving either the lower end of the femur or upper end of the tibia, or both bones, with or without destruction of the joint, is followed in about 50 per cent. of the cases by deformity."[4] The same is true of the hips, and certainly these results are not what they should be. Following burns of the various parts of the body, deformities often occur, and in most cases could and should have been prevented. Contracted fingers, elbows drawn to such an extent that the hand nearly touches the shoulders, feet in marked equinus or calcaneus, extreme torticollis are illustrations familiar to all surgeons. After operations on bone, deformities often occur. They are due to failure to realize that although an excision of the knee has been skilfully performed, yet the union is not firm enough to support the body weight for many months. "For the prevention of flexion deformity it is necessary that apparatus be worn for a very considerable period after the operation,"[5] and this is also true of other articulations. After operations on muscles for the relief of deformity, care must always be taken lest the same recur.

To faulty decubitus in any form of illness many deformities are attributed, and these can nearly always be prevented. A flexed knee, a contracted heel-cord, a deviated spine, are familiar examples, requiring subsequent tenotomies, myotomies and even operations on the bony system for their correction. The amount of damage done in this manner is but little appreciated, and to recommend that the knees of every typhoid patient be stretched daily, or even fastened to a straight posterior splint would probably cause most medical men to believe that the one suggesting it had lost his reason, but the writer has seen subluxation of the tibia and such extreme hamstring contraction follow in some cases that, despite the best efforts of the surgeon, the knees could never be restored to their normal condition. Every surgeon can recall instances where forcible stretching and myotomies had to be done for the relief of deformities that the patient could have prevented had the family physician or nurse simply made the suggestion that the knees or feet be occasionally stretched.

---

[*] Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

In synovitis, in rheumatic joints, in septic conditions of soft parts or articulations, the possibility of faulty positions becoming permanent should always be taken into consideration. A shortened lower extremity from any cause, a tilted pelvis, an inflamed joint or inflammation of the soft parts may lead to spinal curvatures that should have been prevented, and it is the duty of all to see that such deformities do not occur.

Faulty position in school, the carrying of undue weight on one side, the failure to properly maintain the erect position are all familiar conditions that lead to deformities that are in most cases easily prevented, and many more examples could be cited. Toe drop from the application of splints, of bandages for knee or hip disease, for fractures, dislocations, sprains or diseased conditions of any kind, is a preventable deformity, because if the foot is kept at a right angle with the leg it will not occur.

Permanent stretching of muscles, as in wrist drop, etc., from palsy of any cause, such as poisoning from lead, can be prevented by simple means; yet many treat the disease and pay no attention to the prevention of deformity. Many congenital deformities are most amenable to treatment, such as the slight degrees of clubfoot, but if treatment is delayed for any cause, the deformity becomes serious and most difficult to treat.

The prevention of deformity, therefore, should be clearly impressed on all those who are called upon to treat any condition that may lead to it, and once it is clearly understood that certain deformities frequently seen can be prevented, many a patient will be spared much inconvenience and subsequent trouble. The extreme deformities often seen might also have been much less marked in many instances if the fact had been recognized in early life that certain precautions should always be taken to prevent their increase, or to prevent other deformities from occurring.

The prevention of deformity is a subject that must be attended to by the family physician, because the surgeon is rarely called until it has occurred. He is asked to correct it by the use of the knife or by some other method, but his best efforts are often disappointing to all concerned, although in most instances he can relieve the condition, if not entirely overcome it.

The methods to be used in preventing any particular deformity will readily suggest themselves to the physician, or can be found in most of the works on orthopedic surgery, and need not be referred to at this time. The plaster of paris dressing is, however, one that can be recommended in many instances, and is cheap and always obtainable. Early and correct diagnosis and the recognition that deformity does occur in many cases must be impressed on all medical men, and then the prevention of deformity will necessarily follow.

DISCUSSION

ON PAPERS OF DRS. JONAS AND TOWNSEND.

DR. H. L. TAYLOR, New York—The prevention of deformities is a question of great interest not only to the surgeon but to the community. Dr. Townsend has presented his case with great clearness, and the point made that many of the congenital deformities were in a sense preventable, is a good one. Those that are easily curable in the early stages are often extremely deformed later if neglected, and surgeons are often confronted with this condition of things. The patients will tell you that they have been advised to postpone treatment until a certain age on the understanding that the patient will outgrow the deformity—and there are cases where this point of view is, in a measure, justified, as, for example, in rickets—but there is seldom any reason for postponing treatment for years and it is poor advice to say that the deformity will be outgrown, unless you are certain that this will be the case. As to the paralytic deformities, only yesterday I had occasion to operate on a case of infantile paralysis in a four-year-old child, the contractions being in front of the hip and behind the knees and ankles, necessitating an extensive operation. Tenotomies of the heel cords and of the ham-string and open dissections to the structures in front of the hip joint had to be done. These deformities are easily preventable. If one-tenth of the attention were devoted to the prevention of deformity in these case of infantile paralysis that is devoted to the employment of electricity, the results would be better. Another class that is often preventable are those deformities which follow fracture, and in two locations this is especially true—for example, in deformities following Potts' fracture of the foot, of which we see scores yearly. If these cases were properly treated by replacement and inversion of the foot in the beginning, they would be prevented. Another class which is not always easy to prevent are the fractures just above the elbow, but careful management on correct principles will usually yield a good result.

Our medical confrères are hopefully striving to limit the speed of tuberculosis, but without waiting for the results of their labors, surgeons may hope by early and exact diagnosis of bone lesions in some instances to remove disease before it becomes dangerous to life or limb through joint involvement. Tubercular disease in or near the great trochanter should be located and removed in many instances before the hip is involved. Brilliant work in this line has recently been done in tuberculosis of the patella, and if attention is directed along this line such opportunities will be increasingly numerous.

As to Dr. Jonas' paper, I think his plan of making a sliding flap to cover a large part of the exposed area is a very good one, but I would limit the deep operation to intractable cases. We can nearly always cure our patients by simpler means, but in the older or in the more severe cases it seems to me he has suggested a very practical means for eliminating the unsightly defect usually left by the Phelps operation, and I thank him for his able presentation and practical suggestions.

DR. H. M. SHERMAN, San Francisco—As to Dr. Jonas' paper, I have to say that the Phelps method is one that I abandoned many years ago, as I failed to get the results I expected. I resorted to subcutaneous work whether it was in soft or hard tissues. The incision Dr. Jonas suggests is exceedingly ingenious, but I think the deep region can be equally well reached by a curved incision with the base downward and convex upward along the side of the foot. You can turn down this flap and do plastic operations on the tendons. It is not the skin that causes the relapse; it is the deeper tissues. Any method which gives free access to them is to be commended.

Dr. Townsend's paper covers an exceedingly wide subject, and unless we were to discuss each individual disease producing a deformity we would miss much. Plainly, it puts another task on the general practitioner, who must know exactly what deformities are likely to occur after each one of the conditions which may confront him. In many such cases a deformity might be prevented, while in others surgery would be required from the very start. This is especially true after burns, for no amount of apparatus will control these deformities. It is wiser, for general reasons, that the general practitioner should have the orthopedist to aid him in all these cases. Dr. Townsend mentioned the contraction that occurred after knee-joint excisions; now sometimes a brace or splint will fail to control them. I have seen these cases go on to producing very bad pressure sores in a primarily well-fitting splint, which absolutely prohibited the flexion. When the splint was changed a little flexion occurred, and as the pressure sores prevented further efficient splinting, the average amount for these cases of flexion resulted. I believe these cases represent a type of secondary deformities of most obstinate character.

DR. A. J. STEELE, St. Louis—I want to say "Amen" to Dr. Jonas' paper. I believe there are very few cases of clubfoot that require interference with the bone, although a certain number of old cases may. Of course, when it is necessary we will have to do it, and I think going through the neck of the astragulus with a chisel is the best way. I have long since given up the Phelps operation. I believe most cases of clubfoot can be cured by subcutaneous surgery, and we should only divide the integument and bones when absolutely necessary. Plaster-of-Paris bandages should be applied to retain the foot in the improved position. Dr. Townsend's remarks are most timely. As our fees come from the cure of these deformities so the average citizen would say you are taking bread out of your own mouth by preventing them, scarcely appreciating our unselfish spirit and act. All that Dr. Townsend has said on the matter is correct. It should be our aim and object to teach the people the facts in the paralytic cases so that deformities may be avoided.

DR. C. E. RUTH, Keokuk, Iowa—This is a subject in which I have been considerably interested for years as these cases have occasionally given me considerable trouble. I have long since abandoned the idea of making a V-shaped resection in severe cases from the outer side of the foot because in many of these cases when the V is extended two-thirds of the way across the foot reposition places the anterior diagonally across the posterior section and the resulting bony contact is not what it should be. The sectioning of the bones even in extreme cases has not in my experience been necessary under four years of age. I have operated on a very difficult case, even at the age of thirty-four, where the soft parts on the inner side of the foot were so short that it would have required a sectioning of everything on the inner side of the foot in order to place the bottom of the foot downward. This case was operated on four years ago, and I secured a good result by the removal of the astragulus. Since then the man has been able to walk, even following the plough or doing any kind of work that he choose without marked inconvenience; there has been no tendency whatever to a relapse. In these cases it is not wise to flatten the foot too much by sectioning the soft parts and thereby abolishing an exaggerated arch. I heartily endorse every word that has been said in reference to the prevention of the deformity. As to sectioning the neck of the astragulus I think it is a very wise precaution in some of the severe cases where the soft parts will permit of replacement. It requires considerable force to retain the parts in a position. I was glad to hear the Doctor say we should use the plaster of paris above the knee and it is wise that when used in that position the flexion should be at least 35 degrees with complete eversion. If we extend the plaster of paris only to the knee there will be a very pronounced in-toeing which is very objectionable. I would like to have heard something about using the tibialis anticus to raise the outer side of the foot by detaching its internal tendinous connections and attaching same to the outer side of the foot.

DR. FRANK WARNER, Columbus, Ohio—Although my experience has been limited, even a few cases should enable one to draw some conclusions. In the correction of these cases of talipes we must do so in such a way that after restoring the foot to a normal position and you let loose of the foot, it will remain practically in that position, or at least require no decided tension to keep it there. Unless you keep the deformity well corrected in putting on your apparatus there is a likelihood of failure. In order to avoid much pressure to keep the foot in position you should make a division of the tissues sufficient to overcome all tension, not minding whether it means the bone as well as the soft parts or not. In relieving the deformity I do not believe it makes a great deal of difference what the character of the incision is. The keynote is to cut enough tissue so that the foot remains in the normal position by slight tension, when the retaining apparatus should be applied; but this apparatus should not be applied until a sufficient division of the tissues has been made so that the apparatus may easily hold the foot in position.

DR. C. E. THOMPSON, Scranton, Pa.—I have treated forty cases of this condition but have never commenced directly at the end of the third stage of labor, although I have begun in a few cases immediately after the baby was washed. The ages of my cases extend from this time up to thirty-five years, but of course this latter class is not the one to be corrected by the hand of the mother or the nurse. I have never done a Phelps operation but have watched very competent men do it sufficiently often to be satisfied that I did not want to practice it. My treatment has been the correction of the deformity by repeated stretchings, subcutaneous tenotomies and fasciotomies and retention in the correct position with plaster of paris casts for a long time. I will have to differ with Dr. Warner when he says that you must have your foot corrected so that it will remain corrected before you put on your appliance. The strongest element that I have ever used in the correction of this deformity is my hand and the patient's weight, together with a plaster of paris cast, so arranged that every step the patient takes aids in the correction of the deformity.

DR. JONAS, in closing—This discussion has been very interesting. It is admitted that the simplest method that will correct a deformity is the one to be employed. If manipulation is sufficient to restore the foot to its normal condition that is all that is necessary. The cases referred to in my paper were old relapsing cases, ones of extreme deformity, such as where the superimposed weight rests on the dorsal surface of the foot, with the plantar surface pointing in and backwards. All who have had experience in this line of work must admit that sometimes extensive operations become necessary and all surgeons will agree that an open operation is preferable to a subcutaneous method. An operation enables one to see exactly what is being done. I believe in the diagonal division of shortened soft structures so far as possible, but in cases where you can make a transverse incision without leaving any dead space between the tendons, one should do so. I have no other comments to make.

THE LEGAL STATUS OF THE TERM "REPUTABLE" AS APPLIED TO DENTAL COLLEGES.*

CHAS. C. CHITTENDEN, D.D.S.
MADISON, WIS.

Uniformity of dental laws and standards in the various states of this country has been a consummation long sought and most devoutly wished by those men who have followed, as well as those who have dictated and guided, the development of our educational methods, with a view to placing the dental profession of this country where it rightfully belongs before the civilized world.

UNIFICATION DIFFICULT.

The comparative ease with which the legal right to establish and maintain schools and colleges in any state or territory is secured is only exceeded by the great difficulties that have presented in all attempts to unify methods, curricula and standards for the conferring of the dental degree.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. G. V. I. Brown, M. H. Fletcher and R. R. Andrews.

As schools increased in number, the estimated value of the dental diploma became more and more an unknown and uncertain quantity, which condition resulted in an effort toward the establishment by the people, through their legislative representatives, of some legal process of measuring and weighing the character and quality of any man's preparation and fitness, before permitting him to offer his professional services to the public.

Since, for obvious reasons, a national standard could not be secured through Congress, it was left for each state to enact its own police regulations. Through the power of association which has been steadily growing during the past forty years, concerted action in the different states was possible in securing legislative enactment. A general and uniform draft of statute was prepared and recommended to the several states by committees selected for that purpose. But concert of action does not always bring uniformity of outcome.

THE LAW IN VARIOUS STATES.

The result has been a multiplicity and variety of dental laws almost as different in their construction as it is well possible to conceive—viewed superficially. For instance, forty-seven states and territories of this country have enacted dental laws, in all but one of which a board of dental examiners has been created.

In twelve of these states no mention is made of the existence of a dental college. Any and all persons so desiring may be examined as to their fitness (no matter where acquired) to practice, and the board, in its discretion, licenses or rejects them. Eight other states, on the other hand, will admit no one to examination who is not a graduate of a reputable dental college. One state, Wyoming, has no board, but admits no one to practice without registering a diploma from a reputable college. Added to these nine are twenty-six other states which, while admitting all who may so wish to be examined by the board, at the same time direct the board to grant license without examination to those persons possessing a diploma from a dental college which complies with such standards and requirements as the law provides.

It therefore transpires that of the forty-seven enactments in this country for the regulation of the practice of dentistry, thirty-five specifically mention the possession of a diploma from a recognized or reputable dental college as a necessary or at least an important factor in securing a license to practice dentistry.

THE COLLEGE MUST BE "REPUTABLE."

The different state laws make different specific requirements of colleges whose diplomas they accept as a qualification for license, but practically all laws provide that the college, after fulfilling all other specifications, shall, in addition thereto, be "reputable." In each and every case the board of examiners is left without any instruction as to the method of procedure in determining the reputability of a college, or as to the scope and meaning of the word "reputable." It is simply prescribed that the college must be "reputable," thus placing upon the board the judicial duty of establishing criteria of reputability and choosing its own methods of applying them to colleges when called to act officially.

Naturally, when standards have been fixed by a board which conflicted with the interests, financial or otherwise, of a certain school and measured by which that school's diplomas are discredited, a definition of the board's powers and limitations has been sought by the use of mandamus proceedings. And there are several decisions extant on the statute books of different states, all sustaining the position of the boards where there was no question as to the competence and good faith of the examiners.

THE WISCONSIN COURT DECISION.

It remained, however, for the Supreme Court of Wisconsin, in a decision handed down Jan. 7, 1902, in the mandamus suit of W. L. Coffey vs. State Board of Dental Examiners, to so fully define and elucidate the whole question of the board's powers, and of what the statute means by the word "reputable," as to set at rest any further cause or excuse for mandamus proceedings.

The state board had officially refused to accept Coffey's diploma in lieu of examination for license by the adoption of the following resolution:

> Whereas, After due and careful consideration, acting under and pursuant to the provisions of Chapter No. 56 c. of the Wisconsin Statutes, this board has decided that in the opinion and according to the best judgment of the board, "The Department of Dental Surgery, ... College of..... ," is not a reputable dental college; therefore, be it
>
> *Resolved*, That this board does hereby refuse to accept the diplomas of said Department of Dental Surgery, ... College of ......, in lieu of examination for license to practice dentistry in this state.

Under mandamus proceedings in the lower court, all the reasons why the board declared this certain college to be, in its judgment, "not reputable," were brought out on the witness stand. These included—besides proof of certain misrepresentations by members of the faculty, under official questioning by the board as to facts concerning the school and its management—deviation from generally accepted standards in matriculation and transfer of students, in equipment, in curriculum, in methods of and facilities for instruction and training and in several other particulars as to the methods of conducting the school.

The lower court held that the board had erred in some of its proceeding, and declared the school "reputable." The board appealed from this decision to the highest tribunal in the state. The Supreme Court reversed the decision of the lower court and sustained the action of the state board at every point in a most exhaustive opinion reviewing the testimony brought out in the lower court.

SUMMARY OF THE DECISION.

The following is the summing up of the law points by the court:

STATE OF WISCONSIN—IN SUPREME COURT.

State of Wisconsin, Ex. Rel. W. L. Coffey, Respondent.
vs.
C. C. Chittenden et al. Constituting the State Board of Dental Examiners, Appellants.

SYLLABUS.

1. The scope of mandamus proceedings to coerce a person or board to the performance of a judicial or quasi-judicial duty extends only to compelling such person or board to act, not to directing him or it how to act, unless the underlying facts are undisputed, leaving no reasonable ground for action other than one way.

2. If a person or board is clothed with judicial or quasi-judicial power in the determination of questions of fact and the taking of some specific action upon such determination, and fails to make a proper investigation of such questions, it is not within the function of a mandamus proceeding, predicated on such neglect, for the court to assume and exercise the duty of such person or board and make such investigation.

3. The character of a dental college or other institution of learning at a particular time may be established by evidence of its character at a prior time not so remote but that it would be reasonable to assume that the prior condition still exists. The rule applies that "when the existence of a person, a personal relation, or a state of things, is once established by proof, the law presumes that the person, relation, or state of things continues to exist as before, until the contrary is shown, or until a different presumption is raised, from the nature of the subject in question."

4. The character of a dental college in April of one year is *evidentiary* of its character in May of the next year, and may have sufficient probative force in that regard to reasonably establish such later character.

5. The word "reputable," as applied to dental colleges in the law authorizing the State Board of Dental Examiners to license persons to practice the profession of dentistry, without examination, who have graduated at such a college having certain specified requisites means *reputable* in the general sense in which the term is ordinarily used: Worthy of repute or distinction, held in esteem, honorable, praiseworthy.

6. In passing upon the application of a graduate of a dental college for a license to practice his profession in this state, the Board of Dental Examiners must determine whether his diploma comes from a reputable source as an independent fact, considering the term "reputable" in its ordinary sense and measuring the character of the college from the standpoint of men competent to judge thereof by reason of their scientific attainments in the line of work for which such a college stands.

7. The State Board of Dental Examiners, *proceeding reasonably*, is the sole tribunal under the statutes to determine the questions of fact to be solved, precedent to the licensing of a person to practice the profession of dentistry in this state.

8. When a graduate of a dental college applies to the State Board of Dental Examiners for a license to practice his profession, the burden of proof is upon him to establish the reputability of such college.

9. The State Board of Dental Examiners, having once determined the character of a dental college, may properly consider all questions in regard thereto at rest till, by lapse of time or otherwise, some reasonable ground exists for believing that its character may probably have changed.

10. The State Board of Dental Examiners having once determined the character of a dental college, within all reasonable limits, when and under what circumstances the subject shall be re-examined rests solely in its discretion.

11. Since the law does not define the method by which the State Board of Dental Examiners shall proceed to determine the reputability of a dental college when that is material to its official action, such board may perform its duty in that regard in any reasonable way it may deem proper, and candidates for licenses to practice the profession of dentistry must submit to its judgment so long as they are within the boundaries of reason and common sense.

(Syllabus by Marshall, J.)

THE DEFINITION OF "REPUTABLE."

Beyond a peradventure the foregoing syllabus definitely settles several things heretofore misunderstood or left in doubt.

First. The intention and meaning of the word "reputable" as applied to dental colleges is "Worthy of repute or distinction, held in esteem, honorable, praiseworthy."

Second. The question of reputability of a college as an independent fact is left to the decision of "men competent to judge thereof by reason of their scientific attainments in the line of work for which such a college stands."

Third. The state board, proceeding reasonably, is the sole tribunal under the statutes to determine the questions of fact to be solved.

Fourth. The burden of proof is upon the graduate to establish the reputability of his college.

Fifth. The state board, having once determined the character of a dental college, within all reasonable limits, when and under what circumstances the subject shall be re-examined rests solely in its discretion.

Sixth. The board may perform its official duty of determining the reputability of a dental college, in any reasonable way it may deem proper, and candidates for licenses to practice the profession of dentistry must submit to its judgment so long as they are "within the boundaries of reason and common sense."

The deduction of your essayist from all this is, that the question of unification of dental laws and interstate reciprocity of license, together with unification of dental educational standards on any reasonably high plane "within the bounds of common sense," is in the hands and entirely within the province and power of the state boards, provided they will act in concert in carrying out the high duties imposed upon them as the dental police officers of their several states, and this, too, without the enactment of any new dental legislation whatever.

The N. A. D. E. and the N. A. D. F. have enacted and adopted rules and educational standards that are acceptable to the profession at large, and have arrived at what general standards should be fixed as the criterion of reputability, but in order to make these "reasonable" standards nationally uniform it will be imperative that each and every state board in the union adapt them to its uses under its state laws and adopt them as its own standard of reputability.

Surely a standard built on such a broad foundation must be considered as coming "within the boundaries of reason and common sense," and therefore may be applied freely in judging the value of diplomas of any applicant for license in any state.

JUDICIAL POWER OF THE BOARDS.

In the twelve states first mentioned where the law compels the examination of everybody and does not make any mention of a diploma (taking the state of Massachusetts as an example), the character and scope of the examination is left absolutely to the discretion and judgment of the board—therefore it is entirely competent for that board to make the possession of a diploma from a "reputable" college as prominent a factor in the examination of a postulant for license as they may deem wise—and thus enables the boards of these twelve states to have as much to say as to what constitutes a reputable dental college as those of the remaining thirty-five states and territories where statutes do give a specified value to the diploma of a reputable college.

So it will be seen that the statute in every state in the union grants its state board all the judicial power necessary to join in the establishing of absolute national standards of dental educational requirements.

There is absolutely nothing in all this proposed unification of standards, etc., by the boards that can react in any but a beneficial manner upon the schools themselves. The element of commercial competition will be eliminated where it exists, and in its stead the spirit of emulation will be greatly stimulated.

THE OUTLOOK FOR DENTAL EDUCATION.

The improvement and advancement in the general character of the dental college course in the past very few years is a fact which gives great promise for the future of dental education in this country.

Few can know and appreciate at how great an expense of energy, time and strength, and with what sacrifice of self and the comforts of life the honest dental teacher carries on his labor of love. Many of our brightest and best men have shattered their health and shortened or sacrificed their lives for the advancement and dissemination of knowledge in our colleges—and in almost no instance has the pecuniary return been in any sense adequate to the sacrifices made, and still the signs of the times indicate that the end is not yet.

The schools are building themselves on broader educational foundations, fitted to support a more elaborate and symmetrical superstructure, whose power and beauty shall command the respect and admiration of the civilized world—as well as set the pace for all Christendom.

School men have at last come to understand that the examiners, with the law at their backs, are a tower of strength in support of all honest educational efforts, as well as a menace to all forms of pretense and sham.

The only way in which this country can establish and maintain its supremacy in dental educational standards over the rest of the world, is by a concerted national legal standard being made by the legal guardians on whom the sacred trust is imposed—and these guardians must deserve and command the confidence and co-operation of the colleges, as well as the profession at large.

The question confronting us to-day is simply whether we as a profession will arise and enter into our birthright.

DISCUSSION.

DR. G. V. I. BROWN, Milwaukee—It is important for us to know that this is the first time that we have been able to take up the discussion of dental legislation with reference to the curriculum of advanced dental education and bring forward such changes as we desire to have made for the elevation of the profession with a certainty that we could carry them out. The term "reputable" as applied to colleges is now defined to mean having a standard which is in accordance with that of the best other similar institutions. This, also, might be extended to imply that a proper curriculum is one in accordance with what is laid down as right and sufficient by those best versed in the educational needs of dental colleges. It seems to me at this time like the opening of a wide vista before us as we contemplate the work to be done, and more especially with regard to the distinct line of progress in which this Section has been interested in for so many years. We can now take up intelligently the consideration of such branches as should be taught, how much and how little of each which are best adapted to the need of a dentist from the standpoint of the artisan purely, and which are more fitted to enable him to rank among the professional men of the world as this Section would have him, taking his rightful place in the rank of medical practitioners without sacrifice of manipulative dexterity. It seems to me that it is a very beautiful tribute we are called upon to receive and acknowledge, this crowning of the labors of Dr. Chittenden and of the other gentlemen who have carried on the work of the Section with high ideals, and to know that these aims are in a fair way to be consummated, to be made to feel, as all must whose hearts are tuned to vibrate in unison with thoughts that lead upward toward professional advancement, with its ultimate aim a beneficial service to humanity, that the members of that august body, the Supreme Court of the State of Wisconsin, are in sympathy with our work, and have taken notice of the self-sacrificing life-work of our confrère, Dr. Chittenden, by making clear the legal complications that for so many years have been our stumbling blocks. Even beyond the apparent necessities of the case in controversy has the legal status of boards of examiners in relation to courts of law and dental colleges been defined. A ruling has been handed down that will govern boards of medical, legal and other examiners as well as dental for years to come.

DR. M. L. RHEIN, New York City—I feel that all of the profession are indebted to Dr. Chittenden for the work of bringing this matter to such a magnificent consummation in his own state. In the East we have read with interest the controversies in the matter, but we felt that our interests were in very good hands. This magnificent decision is unquestionably a tribute to the esteem in which Dr. Chittenden must be held personally in the state of Wisconsin.

One of the things we have been striving for in our state is to get a unity of understanding so that the bearer of a license to practice in one state could practice in another. We hope that the present reciprocity between some states of the right to practice may be extended to other states. It is an unwarranted hardship to ask a man who has been practicing for some years to pass the ordinary examination. However, it would be folly for us to take into some of our states practitioners with the endorsement of some of the boards of examiners.

DR. A. E. BALDWIN, Chicago—I am glad that Dr. Chittenden has been able to present this paper to us and to the profession at large through THE JOURNAL of the American Medical Association, because it is a move in the direction of higher standards, higher education and broader qualifications. To my mind it marks an epoch which will be more readily recognized in the future. It seems to me that this so-called reciprocity in professional work should obtain. It is in every way reasonable and equitable, and once established, I believe it will do more for the elevation of dentistry than any other one thing. I feel that I can endorse very heartily the tribute of Dr. Brown to Dr. Chittenden. For fear of it being misunderstood by the readers of this paper, I want to say that I do not think this decision of the Supreme Court of Wisconsin was qualified in any way by the personal opinion of the Supreme Court judge for Dr. Chittenden. I do not think that was the meaning of Dr. Rhein. The decision of the court will be even more far-reaching than is perhaps now realized.

DR. RHEIN—I trust that my remarks did not bear the interpretation suggested by Dr. Baldwin. I meant that the record of our specialty coming through such a man as Dr. Chittenden proved that we are in a position to receive such a decision.

I would like to say, in regard to the troubles in Germany last year, and which were taken up by our consul, that in returning last summer from Germany one of our passengers was Professor Andrew D. White, our ambassador to Germany. It was a matter to me of great pleasure to see the interest taken in our specialty by Professor White, and desiring to send a message to those interested in this work in America, he said he wanted us to know that in anything in the nature of international complications he placed himself at our disposal, and wanted us to feel that we could have access to him at any time in reference to such matters as had come up last year.

DR. E. S. TALBOT, Chicago—If the state boards adopt the law as explained by Dr. Chittenden they have an immense power to wield in regard to dental colleges. The word "reputable," and in another clause "the burden of proof placed upon the graduate as to the reputability of the college" covers the ground. It relieves the state boards of much hard work and at the same time gives them the ability to maintain high standards. In taking this position the judge seemed to have an insight into the conditions and affairs and to have made it plain that any state board with the least amount of ability could place their board in a position to command the respect of all the colleges in the country.

DR. BROWN—As a matter of fact, reciprocity is a possibility and can easily be an actual fact. I do not suppose any of you will remember the Chairman's Address which I read at Columbus, but at that time I outlined the possibility of an arrangement whereby all individual boards could be guided and supervised by the National body and made the statement that though individual members of boards might in some instances prove to be mercenary and ignorant, and have secured their positions as a result of political appointment, a selected committee from the best representatives of all of the boards of the United States would be as nearly fair and honorable a tribunal as would be possible to secure. The board of Wisconsin has made all that possible. Under the direction of their attorney this board has prepared its own rules. Instead of being guided by the National body it has adopted for its governance certain rules and regulations, based on the rules of the associations. Under the decision of the Supreme Court its members can require just exactly whatever the rule demands and thus, as they see fit, can raise the standard. The board is a judicial body and in the reasonable exercise of its proper powers can not be overruled by any court of law. If the different boards choose to adopt similar rules and regulations under these conditions the standard will be at once uniform and it will then be possible for reputable graduate licentiate practitioners to go from one state to another without being harassed by examinations, as they should be allowed to do. On the other hand, a safeguard is provided that takes away the possibility of having too loose or haphazard methods.

A part of our work for the future should be to prepare a way for the proper education of the dental student, for a wider medical education as a prerequisite for his full recognition as a reputable dental practitioner.

DR. J. L. WILLIAMS, Boston—If we can get good men on the state examining boards there will be no difficulty, but in some states the boards are ruled by politics. I think it is quite proper that the examining boards should have the legal power if they are well qualified and honest men.

DR. A. H. PECK, Chicago—The subject has been so entirely covered that I will simply say this, because I am anxious to go on record before the dental world and before the medical world as one who is in favor of everything which tends to uplift our profession. This has been my sentiment for years, and I am exceedingly glad that we have one man who has been on a state board of dental examiners for years, who has given the best part of his energy to the consummation of some plan as a standard for the future. Dr. Chittenden is the man, and he has given us to-day a careful résumé of the laws of the various states and their attitude toward dentistry. It is for us to say whether a school is reputable or not. I hope, further, that the power may be placed with them of determining the value or the reputability of a diploma given to a graduate by any institution. Men and women are turned out of our institutions with their diplomas who are not capable or should not come before the world as graduates of any reputable institution. So long as I hold a guiding hand in the affairs of an institution my efforts shall be in this direction: to uphold every effort of the state boards throughout the country looking to the elevation of the standard of dentistry.

DR. G. F. EAMES, Boston—I heartily endorse the statements so far as I have heard them, especially the remarks of the Chairman, and so far as I have looked over the paper. There is a great deal to be done with the state boards themselves, in my opinion, for certainly their methods of examination and questions that they have proposed, whenever they could be ascertained, have been far below what I should term a reputable standard.

Any further word that I might say would simply, if possible, make emphatic the suggestion of the unification of these laws and standards. When the standards of examiners in all the different states, or any number of states, are of the same degree, and of a satisfactory grade, then, it seems to me, it would be a very easy matter to enact laws by which a practitioner, having passed successfully one state board, may be admitted to practice in any state having an equivalent standard of examination.

DR. BALDWIN—If it would be in order, it seems to me it would be proper for a resolution of recommendation to go from this Section to the National Board of Dental Examiners requesting in the name of the Section on Stomatology of the American Medical Association that they look with favor on this interpretation given by the Wisconsin Supreme Court.

DR. CHITTENDEN, in closing—The difficulty in the past has been that the boards of examiners were antagonized by the schools and there was a spirit of commercialism in the faculties themselves and it was only after a serious struggle that it was possible for the examiners to get the colleges themselves to set a definite educational requirement for admission to their schools. From that point we have gone forward and the years intervening have brought the two institutions more closely together. Last year the faculties' associations recognized that the examining boards were really becoming their friends. The suggestions which I have endeavored to show you are absolutely feasible for the establishment of a National educational standard which may set the pace for the world. It is understood and known that the law of New York State is the best and the one requiring the highest standard in the United States. It has seemed to most men interested in dental matters to be a standard sufficiently high to be sought and chosen as a criterion to which all boards should come. The matter must necessarily move slowly. The boards are scattered throughout all the states of the Union and it is difficult to get them to coöperate. Once the colleges encourage what I have undertaken to describe, the boards will understand that it is a desirable thing. As soon as the educational standard was permanently established in 1899 commercialism practically ceased. With the standard as it is, no school can matriculate a man unless he can present credentials acceptable to the state superintendent of public instruction.

I can see no question, Mr. Chairman, that the propositions made in the paper are not absolutely feasible; that they may not be put into action and in that way enable us to set a standard of dental education for the world.

DR. BALDWIN offered the following resolution:

Resolved, That the Section on Stomatology of the American Medical Association heartily endorses the decision of the Wisconsin Supreme Court as to the judicial powers of the state board as to the determination of what constitutes "reputability"; and we heartily recommend this decision to the National Association of Dental Examiners as a basis for establishing professional reciprocity in our grand country.

On motion the resolution was adopted.

THE SYMMETRY OF OUR VISUAL APPARATUS AS A DUAL ORGAN.

A PLEA TO MODIFY THE CUSTOMARY NOTATION OF THE OCULAR MERIDIANS.[*]

HERMAN KNAPP, M.D.

NEW YORK CITY.

Our visual apparatus is a dual (paired) organ, symmetrically placed on both sides of the median plane of the body. In the skull the dual parts coalesce at two places, the chiasm and the quadrigeminal bodies which are cut by the median plane, whereas in all other places the dual parts are so arranged that each of their points on one side has a corresponding point at equal distance on the other, as if one side were a reflex image of the other, cast by a plain mirror substituting the median plane of the body.

Outside the skull, all the remaining parts, orbits and their contents, as well as the eyeballs with all their intricate structures, follow the same rule; each point has its correspondent at the same distance on the other side of the median plane of the head.

My purpose, at this place, is to consider only one part of our visual organ with regard to the law of symmetry, the refractive apparatus. A complete analysis of the final refractive effect would require the determination of the curvature of the anterior surface of the cornea, the curvature and position of the surfaces, as well as the coëfficient of refraction of the lens, and lastly, the inclination of the cornea and lens toward the optical axis of the eye, i. e., the centration of the refractive system.

It is well known that the anterior surface of the cornea has a greater influence on the refractive effect than all the rest of the system together.

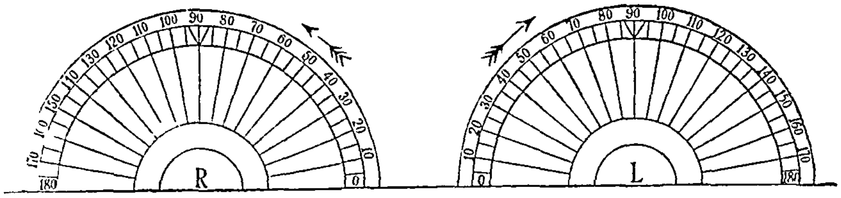
The cornea—meaning its anterior surface—is not a part of a regular geometric body, but what mathematicians call a skew surface (*surface gauche, windschiefe Fläche*), in which the meridians differ from one another. causing a visual imperfection, the correction of which is one of the chief objects of the oculist's practice—astigmatism. The ingenious modification of Helmholtz's ophthalmometer by Javal and Schiœtz is accurate enough to determine the existence and degree of astigmatism as well as the direction of the principal meridians of the cornea, but falls short to determine the astigmatism of the whole eye, which not infrequently is influenced appreciably by the system of the crystalline lens. The determination of the astigmatism of the whole eye is satisfactorily done objectively with the ophthalmoscope by the direct method and the shadow test. The final test, however, always consists in the best correction of the vision with glasses. In this way the refractive condition can be determined with great accuracy. By these examinations which every oculist has to make daily, it has come out that the principal meridians may be found in any position, yet with varying frequency.

---

[*] Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott.

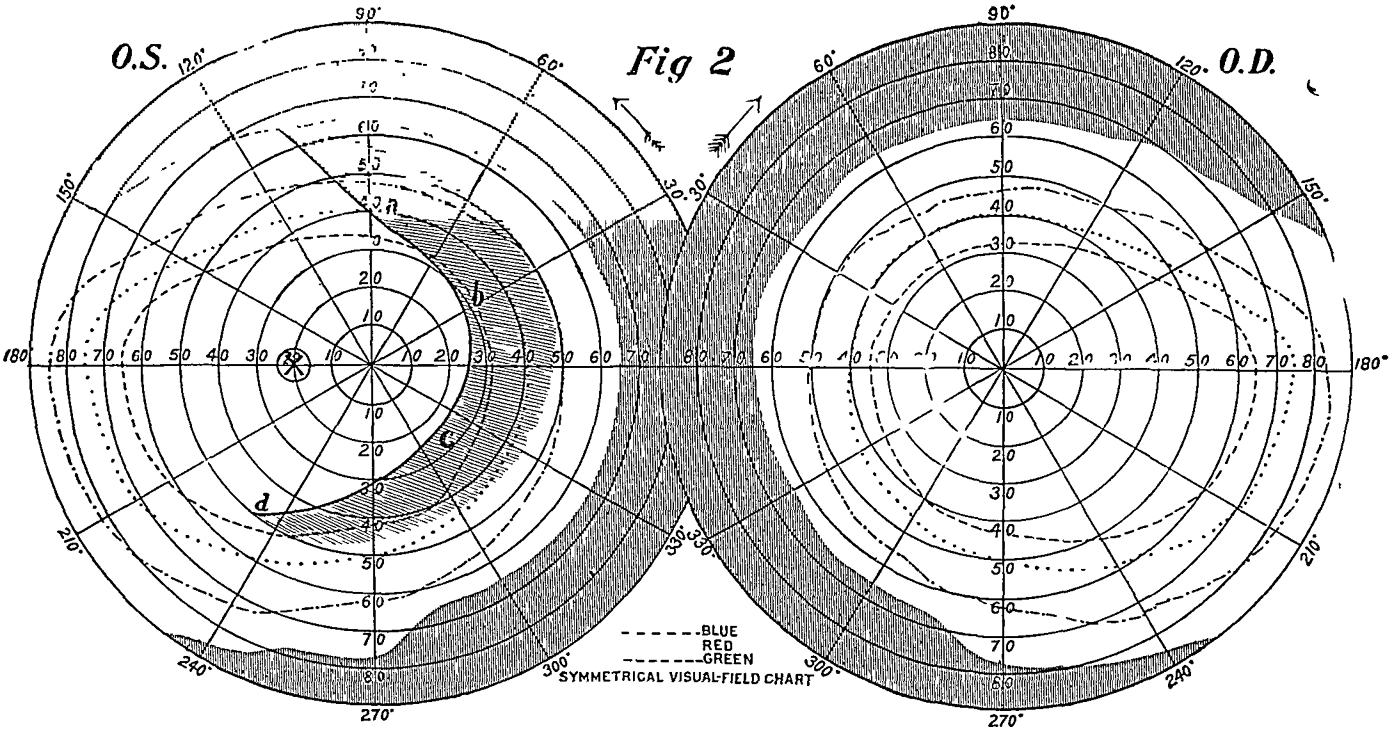
The writer published in the Transactions of the American Ophthalmological Society[*] 1,000 cases of astigmatism with regard to the position of the meridians, and in the Transactions of the Ninth International Ophthalmological Congress at Utrecht[†] 1,473 cases more, the statistics of which were: 1, in 78 per cent. the meridians were symmetrically placed, in 22 per cent., asymmetrically; 2, the vertical meridian had the strongest curve in 56.5 per cent.; next in frequency came the horizontal, with 10.3 per cent.; 3, in the intermediary positions the strongest meridian inclined to the nasal side about twice as often as to the temple. Similar observations being in accord with these statements, and being well known, we need not go into further details.

Now, which will be the best mode of recording the results of our examinations of astigmatic eyes? Snellen and other leading oculists use and recommend to take the vertical median plane of each eye as the basis from which to proceed, because it is parallel to the median plane of the body. Starting from the upper end of the vertical meridian, counting on both sides from zero down to the horizontal meridian, they call the degrees on the medial side plus, those on the lateral minus. I have used this system long, and proposed its adoption at the Seventh International Ophthalmological Congress at Heidelberg in the year 1888, and at the American Ophthalmological Society in 1892, only replacing the plus and minus signs by the indices n (nasal) and t (temporal), which Snellen (see preface to the last edition of his test-types, 1902) is willing to substitute for the plus and minus signs that require an explanation and readily lead to clerical errors.



SYMMETRICAL ASTIGMATISM CHART
PUBLISHED BY GALL & LEMBKE, NEW YORK
Figure 1.

Fig 2



PUBLISHED BY GALL & LEMBKE, NEW YORK.

O. S. Blind spot me 180, pa 20. Glaucoma a = me 90, pa 40, b = me 30, pa 29; c = me 325, pa 23; d = me 236, pa 50.

O. D. Green-field me 0, pa 35; me 60, pa 32; me 120, pa 37; me 170, pa 60, me 180, pa 64; me 210, pa 60; me 242, pa 50; me 300, pa 40.

At the Seventh International Ophthalmological Congress at Heidelberg in 1888 I recommended a second system of notation of the meridians and the field of vision as equally suitable, namely, to begin at the nasal end of both horizontal meridians, mark them 0°, and count upward and all around the circle until we return to 360°, coinciding with the starting point 0°. I said:* "If this system should be chosen I would accept it with pleasure. It is expedient, perspicuous, plain and precise. Clerical mistakes between + or n and — or t would not occur."

[†] Page 65.

At the last International Ophthalmological Congress† I brought up this subject again in one of the general sessions with a view to establish a uniform designation of the meridians of the eye and the field of vision as well. I no longer advocated the vertical meridian as the basis, but recommended the second system, which I had declared as equally suitable at the Heidelberg congress, and which departs only slightly from the system most common in America, is in perfect harmony with the principle of symmetry, and our diagrams will read the same whether looked at from in front or from behind.

The American method has the disadvantage that it disregards the symmetry in the position of the meridians; for instance, of the temporal diagonal meridians the left is marked 45 degrees, the right 135. If we begin the count on the nasal end of each horizontal meridian both would be marked 135, as they should be, being identical.

In the system which I propose we have just as rational and convenient *a chart for the visual field* as for the meridians. The chart contains meridial and parallel circles all around. Any point, any defect of F., can be clearly designated by two numbers, that of the meridian and that of the degree of latitude, just as the mariner designates the position of his ship by the longitude and latitude on his charts. This can be put into the text of a written or printed report as well as the formulas for astigmatic spectacle glasses. Anyone that wants to map it out need only transfer to the chart the points of outline of the defect found by the examination. In our daily practice a cursory examination of the visual field is as indispensable as that of the acuteness of sight. Locating the blind spot gives us an angle of 20 degrees from the visual line as a basis for the diagram in our case book. Whenever a more accurate determination is important, the perimeter and the chart book are always at hand. The points in the upper half of the field of vision are designated by the crossing of points of the meridians from 0 to 180 and the respective parallels, the points in the lower half by the meridians from 180 to 360, i. e., 0 and the respective parallels; for instance, the blind spot X is located at me 180°, pa 20°. If we abridge meridian into *me*, and degree of latitude into *pa*, we can easily mark down the outlines of any line or figure in the visual field. See the notation at figure 2. In noting the crossing points the letters *me* and *pa* may also be omitted, it being understood that the first number of each pair of degrees always refers to the meridian, the second to the parallel; for instance, 190°, 30° = me 190°, pa 30°, means the crossing point of the 190th meridian with the 30th parallel.

As far as I have given this subject thought and action, the proposition which I made as my second choice at Heidelberg, as my first choice at Utrecht, and, in a more elaborate shape now make before you, gentlemen, is, to my mind, the best among the many that have been tried. It rests on a scientific basis, is of easy application and meets the requirements of our daily practice as well as—personally, I should say better than—any other. Will it have a sufficient advantage over the one that has been in use in America almost generally for so many years? I think it will. I hold myself partially responsible for the customary—call it the American—system. Shortly after I had made this country my home (in October, 1868) the late Dr. Henry D. Noyes of New York came to me with the question: "What manner of designating the meridians would you consider the best for us to adopt?" I told him the one which physicists generally use and Helmholtz has followed in the chapter on the movements of the eyes in his "Physiological Optics," viz.: "Start from your left side and proceed to your right as the hands of the clock." Dr. Noyes asked no more. I find he had described this system at the Fifth Annual Meeting of the American Ophthalmologic Society, July 21, 1868.[1] From that time the method began to spread in this country.

The American method is best adapted for problems of motility where the requirements of single vision demand harmony in our motions as if the two eyes were blended into one. The problem before us, however, is merely optical, its solution rests on immutable anatomic conditions in the investigation and appreciation of which the symmetrical position of the meridians is the controlling principle.

The change from the old system into the new would be simple. 1. It will require a new plate on the spectacle frame for the left eye, placing zero on the nasal and 180 degrees on the temporal side. 2. A diagram of the prescription with the same change for the optician marked: symmetrical notation, to distinguish it from the customary notation, which may be called homonymous. 3. Perimeter charts marked symmetrically, i. e., zero at the nasal end of both horizontal meridians. Counting the meridians from the inner canthus up, along the brow, temple and cheek to 360 degrees or zero at the inner canthus. When these changes are made there will be no confusion and we shall be accustomed to the new system in less than a week.

DISCUSSION.

DR. S. D. RISLEY, Philadelphia—I am not unmindful of Dr Knapp's courtesy in requesting me to open the discussion I am impressed by this all the more by the fact that on a former occasion I was not convinced of the greater value of the methods he has advocated than the one in general use in this country and felt it my duty at that time to oppose the adoption of the first plan now again suggested in this able paper. It was then a cause for profound regret that I could not agree with the conclusions reached by one whose life has been one of singular and untiring devotion to scientific medicine and whose labors have in such preëminent degree enriched our knowledge and proved a constant source of instruction in the art of ophthalmic surgery. After a careful reading of the paper, which with great kindness was placed in my hands for study, I am still unable to see any sufficient reason to abandon the methods employed for the past thirty years, and confuse the records which have been made by the adoption of a new, unless an unquestionably better and more scientific method.

In 1893 this subject was brought before the Ophthalmic Section of the College of Physicians of Philadelphia in a paper presented by Dr. George C. Harlan, in which the many attempts which had been made to reach uniformity were set forth. The resulting discussion revealed much diversity of opinion and resulted in the appointment of a committee consisting of Dr. George C. Harlan, Dr. William Thomson and myself. Drs. Thomson and Harlan reported in favor of a plan similar to the second one suggested by Dr. Knapp, viz., that zero should be at the nasal end of the horizontal meridian of each eye. I then felt it incumbent upon me to urge the retention of our present method and set forth my reasons in a minority report, which I now present, since it still expresses my views.

Before abandoning the method with which we are familiar, and which is in almost universal use in this country, we should carefully consider its advantages and scrutinize the objections that have been urged against it. In the first place, it is not only the established and well-understood method in this country, but is based on principles with which we have been familiar since our earliest school days, and is intimately embodied in the work and records of all scientific investigation, where the circle is a rudimentary factor in the process employed. In our first introduction to mathematical studies we found on the protractor the left hand end of the horizontal line designated as zero and the degrees of linear development on the arc of the circle counted upward by right ascension after the manner of the astronomer. The same method has been from the earliest times employed in graduating the quadrant, sextant, and the meridians as employed by the geographer and astronomer, and more recently on the perimeter and the ophthalmometer. In a word, in all the sciences where the circle is introduced the eastern, or left hand end of the horizontal line has been adopted as the starting-point and the degrees counted upward by right ascension to the zenith. This method is indissolubly joined to the records of the mathematical sciences, and is readily understood by all. When direction is given to place the axis of a cylinder at, e. g., 30 degrees, no reference being had to spectacles, there is not an optician in the world who would not place it as desired, since it would be plainly indicated on the protractor. No one outside the realm of ophthalmology would ever think of getting behind the protractor, and thus reversing the angle. We should, therefore, hesitate before we divorce our ophthalmological records from a method employed universally among scientific men laboring in other fields.

If we adopt the median line of the face as zero, we not only separate ourselves from this universally understood method of estimating and noting degrees upon a circle, but it will be necessary to keep in mind a right and left ascension and we can never be sure that it will be understood without explanation, except by the initiated. In my judgment this will introduce complexity. In place of conceiving under all circumstances a development upon the circle from left to right, we shall be compelled to conceive a development from right to left for the patient's right eye, and left to right for the left eye.

The real cause of confusion, if any, in the system we now employ, is in referring the angles of deviation to the respective eyes of the patient, whereas it should, as in other things, be compared to the horizon line. Personally, I have not found difficulty in doing this, i. e., in viewing the angle from the standpoint of my patient. This presents no more difficulty than in differentiating between the patient's right and left eye, examining them from the front as we usually do, the right eye being opposed to our left. This process of orientation is one we must perform in many details of life. With regard to the symmetrical placing of the meridians in the two eyes, etc., I can see no practical advantage in referring them to the median line of the face, that does not obtain equally for the universal horizontal line.

As regards symmetry and asymmetry of the corneal meridians in astigmatism, our present system has an advantage in another respect. It will be found that in all symmetrically arranged meridians the total for the two eyes will be 180 degrees, e. g., both axes at 90 degrees equals 180 degrees. Each incline from the vertical 15 degrees would place the axis of the correcting cylinder at 105 degrees in one eye and 75 degrees in the other, equal 180 degrees, at 45 degrees and 135 degrees, equal 180 degrees, etc. In any case where their sum is not 180 degrees we have asymmetrical meridians.

Dr. Edward Jackson, Denver—The symmetry of the principal meridians of astigmatism is so constant that I can not conceive of any one working practically at the refraction of the eye without very quickly learning some way of immediately determining whether meridians are symmetrical or asymmetrical. To one, as I understand Dr. Knapp has done, who uses the system of notation in which symmetry is recognized by identity of numbering, it may not at once occur that it can be recognized without identity of numbering, in such a way as Dr. Risley has just referred to, e. g., by simply associating in the mind 105 and 75 degrees, or 45 and 135 degrees, etc.; as every one must have done who works with the so-called American system. Most of us, I think, are not conscious of any obstacle in this; and those of us who have learned to use the American system would for a long time find the change a greater obstacle. So much for the designation of the meridians of astigmatism. The Doctor has also touched upon the designation of the field of vision and of the ocular muscles. We must have same system of notation for both of these purposes and the ordinary system seems almost essential for designating the movements of the eye. Its advantages are very obvious. For designating the field of vision there occur to me certain advantages in the American method worth alluding to. The visual apparatus exhibits throughout a bilateral symmetry. But at the chiasm the significance of the symmetry changes; and that change is important with reference to the designation of the field of vision. Lesions behind the chiasm causing homonomous hemianopsia give rise to the large majority of defects which involve the fields of vision for both eyes, and requiring some comparison the one with the other. Now the two fields as charted in a case of homonomous defect do appear exactly similar in shape. Yet, if we compare it by meridians, the extent of the field, say at 15 degrees for the right and left fields, any defect has precisely the same significance for the two eyes. For homonomous hemianopsia we have an advantage in the present system. Then, in making any change of this kind it is important to consider the methods used in other branches of science. Dr. Risley has alluded to the universal use of our "American" system in other branches of scientific work. But if we go beyond that and consider the value of certain other very arbitrary systems we are struck by their universal use. Take the ten digits, for example; few things could be more arbitrary, and yet see how they are used. If there is anything more widely used than that, it is our still more arbitrary alphabet. The general tendency is to get some one basis and use it in many departments of life; and with us it seems to me that we will do best to continue using a system adapted to other departments of science as well as our own.

Dr. Swan M. Burnett, Washington—At the outset I am compelled to withhold my acceptance of the thesis advanced by my honored master in ophthalmology, Prof. Knapp, that the visual apparatus in man is a dual organ, in the same sense that the hands are, for instance. On the contrary, in my opinion both the anatomic structure and the physiologic function of the apparatus point to the necessity of its being considered as a single, or cyclopean eye. The right side of the brain presides over the right half of this eye—the right side of both globes—and the left side of the brain presides over the left half of this eye—the left side of both globes. Moreover, in consonance with this, the synchronous action of the external muscles of the two eyes with their appropriate centers of coördination, move these corresponding halves simultaneously in a manner necessary for maintaining this relation. Whenever they are not moved in this manner, together, we have well-recognized pathologic states. Single vision with the two eyes is possible only by this association of the corresponding halves of the two globes as a physiologic unit. The objective aim in the treatment of a very large number of cases is to maintain the physiologic identity of the corresponding halves of the two globes made essential by the existence of the cyclopean eye.

We must, then, consider the visual apparatus from a physiologic point of view, as one eye with a right and left side. In pathologic states, as shown in affections of the visual field due to lesions behind the chiasm, the same law holds—a lesion on the right side affecting only the right side of the two eyes, one on the left side affecting only the left half of the two eyes. The symmetry of the visual apparatus, therefore, does not consist in the relations, nasal and temporal, of each globe separately to a vertical plane, but in the relations of this single eye to a single plane—the horizontal. In other words, the cyclopean eye has no nasal or temporal side, but only a right and a left side. In such a badly-constructed piece of mechanism as the human body, where asymmetry in a greater or less degree may be considered the rule rather than the exception, it could hardly be expected that the refracting media of the visual apparatus should wholly escape, especially as it involves two separate and distinct structures, the cornea and lens. The special kind of asymmetry with which we have now to deal is astigmatism. There is one well-recognized form of this, so common as to be considered almost a normal condition, and has for this reason been designated "according to the rule." Here the vertical meridian is more strongly refracting than the horizontal. The reverse of this, with the horizontal meridian more strongly refracting, is next in order of frequency. Both, however, conform strictly to the demands of the cyclopean eye. All other irregularities in the position of the principal meridians conform to no general law, and we must from a scientific standpoint consider them as aberrant.

In order to determine how far this law holds good in actual application, I examined two series of cases of astigmatism, of a hundred each, taken in succession, but at different periods as to dates, from my case-books. In these the percentages were quite closely the same for the two series, that is, in about 50 per cent. the two meridians were horizontal and vertical, "according to the rule"; in 15 per cent. the relation was the reverse of this, sometimes called "contrary to the rule"; about 5 per cent. had an astigmatism with the rule in one eye and inversely in the other; and, in about 30 per cent. the meridians were oblique in one or both eyes. Of the cases with oblique meridians in both eyes, there were in the first hundred, 9 with the axes nasal or temporal in both eyes, but of these only 2 had exactly the same degree of deviation from the vertical; in the second hundred, 14 were nasal or temporal in both, with only 3 of the same degree in each eye. On the other hand, in the first hundred there were 2 with both axes inclined either to the right or left, and in the second hundred there were 5 so inclined. Of the remaining there were in the first hundred 18 with an oblique axis in one eye only, and in the second hundred 11 were so situated.

If these statistics are to be taken as any indication, and I regard them as fairly representative, we must regard as the normal asymmetry of the visual apparatus, one in which the two principal meridians are horizontal and vertical, this being the condition as found in about 70 per cent. of the cases of astigmatism. This also conforms fully to the requirements of the cyclopean eye. In the remaining 30 per cent. there seems to be no deviation of such regularity and frequency to establish it as a law. It is true that in 9 and 14 cases, respectively, in the two hundreds the axes were inclined in each of the two eyes to the nasal or temporal side, but in only 2 and 3 cases to the same degree, while they were inclined to the same side, right or left, in both eyes, in 3 and 5 cases. In the larger number of cases, that is, 18 and 11, in the two hundreds, there was an oblique axis in one eye only. If there were a law of symmetry of obliquity we should expect, if there were an inclination of the axis in one eye, to find a corresponding inclination in the other. I can not, therefore, consider it justifiable, or strictly scientific, to take any single aberration from what appears to be the physiological state as a basis for the establishment of a law and for the inauguration of a new system of notation. The two systems of this kind which have been advocated are: first, the adoption of the vertical meridian as a point of departure, and counting to the nasal and temporal sides of each eye to 90 on the horizontal. This I consider not only unscientific, since it is out of keeping with any manner of notation of degrees employed in scientific work, and not in harmony with the idea of a cyclopean eye, since it divides the eyes into four separate and distinct parts, but is needlessly complicated in its practical application. Second, the method brought forward by Prof. Knapp, in which the numbering [illegible] the nasal side of each eye and goes on continuously to [illegible]al side, 90 degrees being the vertical in both eyes. To this method less objection should be made, practically, than to the other, for it is simpler, easier to use, and the liability to confusion is less. The objection from a scientific standpoint is, however, the same. It does not conform to the idea of a cyclopean eye, but divides the visual apparatus into two lateral halves, for which we can find no warrant either in physiology or pathology of the visual organ. Neither can I see any practical advantage. You have two semi-circles with the gradation running in opposite directions, which is not in accordance with the use of the protractor in any other branch of scientific work.

This question is not a new one, as you are aware. In 1885, or thereabouts, a good deal was said about it in Europe, and the vertical meridian was strongly advocated by many as the point of departure for numbering. In 1887 I sent a communication to the *Annals d'Oculistique*[1] strongly upholding what has since become known as the American system, from its almost universal use in this country. In taking only one semicircle, commencing with zero at the left hand and going on to the right as the hands of the clock move, to 180, for both eyes, we are committed to no law of aberration, use a strictly scientific method and have only one direction to hold in the mind in the reading of the position of the axes. Nothing could be simpler, nothing more efficient, as it conforms fully to the requirements of the ideal cyclopean eye. I can see no just grounds for abandoning it for one which possesses none of these advantages, but has considerable disadvantages of its own.

Dr. John E. Weeks, New York—I want to protest against the idea of starting out in the refraction of an eye with the belief that symmetry exists in the sense in which it has been spoken of here to-day. I agree with Dr. Burnett, that we must regard the eye as a single organ. I have been brought to this belief by the examination of the cases coming to my office. I looked over the cases seen in my office in one half of the year 1901 and found that they numbered 473, and that of these cases only 56 presented the condition of symmetry. In 275 cases there was asymmetry, in 92 astigmatism of one eye only, and in 50 no astigmatism. I believe that if a man starts out with a preconceived idea that he is going to find a thing, he is very apt to find it, whether it exists or not, and my position is simply one of caution, that is, to urge the commencing of an examination without any preconceived idea of what you are going to find.

Dr. Knapp, in closing—As to Dr. Weeks' remarks, I did not start out with the preconceived idea of finding astigmatism. The idea was forced on me, as it will be on any one who examines the eye. It was not until 1857 that by measuring the eye this imperfection was found, and it was that which explained why cylindrical glasses improved sight. The man who in 1857 at the German Ophthalmological Society at Heidelberg brought out that idea was your humble servant, and the man who opposed it was Donders.

Dr. Risley has said that in symmetrically arranged meridians if the axis is 105 in one eye it will be 75 in the other; why not denote these identical meridians with the same number?

As to the field of vision, there is no mode of describing or recording it in letters and numbers simply and correctly that I know of. Authors say a foreign body is so far up or down, or so far away from the papilla, etc., while with the method I propose we can go all the way around and put the location down definitely. It always is at the crossing point of a meridian with a parallel.

With regard to the mechanism of the motions of the eye, both eyes act together as one, "the cyclopean eye," but I do not see what the cyclopean eye has to do with a description of the anatomic conditions of each eye, the abnormities of which, with the differences between the two, we have to find out, to preserve in our records, to send to the optician to grind glasses to order, which correct these abnormities, and to send to the press. Is it not desirable to have for these descriptions of our daily work the simplest, the most correct, the most scientific expression, to be understood at sight all the world over?

---

AMEBIC DYSENTERY IN MICHIGAN.[*]

GEORGE DOCK, M.D.
ANN ARBOR, MICH.

The recording of a single case of amebic dysentery can be justified only by particular circumstances. In this case the geographic source of the infection is my chief reason, a secondary cause being the desire to emphasize the need of further work in this class of cases.

THE CASE IN POINT.

History.—H. S., farmer, 30 years old, was admitted to the medical clinic of the University Hospital, Ann Arbor, Dec. 6, 1901, on account of frequent loose stools, containing blood and mucus, pain in the abdomen, tenesmus and loss of weight and strength. The family history is negative. With the exception of chicken-pox, measles and diphtheria in childhood, the patient has always been well up to the present illness and continued his work until the day of admission. He states that his food and eating habits have always been good; does not use alcoholics. Drinks well water, the well being 24 feet deep, 100 feet from the barn, free from contaminations and the water considered unusually good. He does not remember having used other water within a recent period. Has not been out of the state since 1893, when he was in Chicago for a short time.

Present Disease.—The present disease began in August, 1901, with a griping pain in the lower abdomen. The stools soon became thin and watery. Bearing-down followed evacuation. There have usually been from six to twelve stools a day, sometimes as many as twenty. The stools have sometimes contained blood and mucus, but not always. They are often very small. Thinks he has not been free from diarrhea more than a day at a time since the disease began. He took treatment, the details of which are not known, but was not relieved; he grew weaker and lost about fifteen pounds in weight. The patient has no other subjective symptoms than those noted.

Examination.—Frame of medium size; muscles fairly well preserved, panniculus thin. Appearance not very ill; mind clear. Skin pale; no edema; tongue pale, faintly marked by teeth, thin white coat, otherwise negative. Examination of lungs negative. Heart negative, except soft systolic murmur in pulmonary area.

Abdomen: About an inch below level of ribs, slight fulness below and to left of umbilicus. Palpation shows a cylindric mass about an inch in diameter in this region; percussion over it tympanitic. No visible peristalsis. Examination of other parts of abdomen and spleen and liver regions negative.

Examination of rectum reveals blood-stains about the anus, a bloody and purulent fluid in the rectum. The mucous membrane of the rectum shows a number of small irregular, slightly elevated gray patches with red margins. The gray coat is very thin and can not be removed by mopping with cotton. Two thick and reddened valves can be seen.

The urine for 24 hours amounts to 700 c.c. sp. gr. 1025. Chemical and microscopic examination negative. The blood shows 4,730,000 red cells, 10,441 leucocytes per c.mm., hemoglobin 90 per cent.

A small quantity of reddish mucus was brought to me in the laboratory when the first rectal examination was made. The appearance of this was so characteristic of amebic enteritis that I mentioned the fact. At the first glance through the microscope, at a fresh drop, large numbers of Charcot's crystals were seen, and among these were several large and active amebæ, containing red blood corpuscles. The patient remained in the hospital three weeks. In this time the stools, the liquid, obtained through a speculum, from the rectum and the material adhering to a rectal tube, usually contained mucus, blood corpuscles, leucocytes, Charcot's crystals and amebæ. Sometimes there were small masses of columnar cells, or very small superficial sloughs. Eosinophile cells were rather numerous in the stools. (10 per cent. eosinophiles in the blood.)

The Amebæ.—The amebæ presented the same characteristics of size, refraction, inclusions and motion as those I reported in 1891, in Texas, and others that I have seen in dysenteric cases in other places. In the present case I measured a number of the parasites, alive, when as nearly round as possible. They ranged most frequently between 20 and 35 microns. The largest one was 38 microns. Not many were less than 20 microns. They usually contained red blood corpuscles, sometimes being as if stuffed full. The nucleus could occasionally be made out. In some cases there were highly refracting, somewhat greenish vesicles which at times showed changes of shape and size. The stools were usually soft, sometimes watery, generally small but sometimes amounting to 200 or 300 c.c. The amebæ were only found in the mucus or small sloughs.[*]

The number of stools was from three to ten daily, except on one day, when there was only one. The odor was more offensive in the beginning than I had usually found it in amebic dysentery. The fecal part contained many bacteria, as usual. After ten days' treatment soft, partly formed stools appeared, without mucus, with few blood-streaks, and containing Charcot crystals but no recognizable amebæ. At this time, as there was a tendency to constipation, a dose of Carlsbad salts was given. This was followed by several watery stools. In a small bit of mucus in the second stool hundreds of active amebæ were found. The superficial diphtheritic patches in the rectum cleared up quickly, but left two superficial ulcers, not undermined. These quickly healed, and by the end of two weeks the mucous membrane was less red and swollen. The thickening in the left side disappeared. The rectal tube caused much less pain than at first. The mass in the left side of the abdomen gradually disappeared. The temperature reached 100.4 the day of admission, but then fell and after the third day never exceeded 99 F.

Treatment.—This consisted chiefly in the use of quinin enemata. This was given at first in quantities of 500 c.c., all the patient could take, of one to one thousand solution. The patient retained this for one to three hours usually. Later he took 2000 c.c. of 1:2000 solution. The amebæ continued active all the time and no marked evidence of improvement could be seen in the other elements of the stools, except that the feces became slightly more consistent. Later, benzozone was given by the mouth in quantities of 1500 to 2000 c.c. of the 1:1000 solution daily. At this time we were not aware of the best method of preparing the solution, and made it up fresh every morning. There was no effect on the activity of the amebæ. The stock of benzozone then gave out and could not be renewed in time to give a more thorough trial. The patient gained 3½ pounds while in the hospital. He was then obliged to go home, where he continued the quinin enemata for three months, keeping a record of his stools and other data and reporting at intervals. He steadily gained weight and had only one or two stools a day. Stools passed in the laboratory on his visits always contained live amebæ, though the stools had partly lost their dysenteric character. March 28 he was put on sublimed sulphur, 20 gr. t.i.d. During the next month he remained about the same. Blood and mucus occasionally appeared with the stools, but the stools were less fluid. Amebæ were always to be found. After a month, April 29, he was put on 10-grain doses of sulphur four times a day. In the three weeks after that he felt better than at any time since the disease began. He had one or two stools a day and amebæ could be found in only small numbers, in minute bits of mucus.

---

[*] Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

[*] The patient's blood serum was tested with a culture of the Shiga bacillus kindly sent by Prof. Flexner, but did not cause agglutination. Cultures of the stools were negative so far as the specific bacillus was concerned. These observations, as well as injections in cats and other studies, were made by Dr. W. E. Griffin, who was obliged to interrupt the work in order to appear before the Naval examining board, and being ordered to report for duty soon after, his investigations were abandoned. I have to thank him and my assistant, Dr. D. S. Grim, for many of the notes made on this case.

RARITY OF THE CASE.

From the facts detailed there is no doubt the case is one of amebic dysentery. It is the first one I have seen or heard of in Michigan, and as the local origin can hardly be doubted, is of particular interest. "Dysentery" is frequently reported in Michigan, according to the reports of the State Board of Health, but very little has been written on its occurrence here, judging from the scanty references in the Surgeon-General's index catalogue and in periodic medical literature. I have not been able to see an epidemic. Many cases diagnosed as dysentery have been sent to my clinic, and I have seen others in consultation. None had histories closely resembling any of the clinical forms of amebic enteritis, and the conditions of the stools were in general not like those of acute dysentery or of the chronic amebic form. Most cases were chronic diarrheas secondary to disease of the stomach or to acute enteritis. Some were diarrheas of pernicious anemia and autopsies on some of these cases showed no characteristic lesion in the intestines. Others could be classed clinically as catarrhal dysentery, and in one of the most severe of these, seen with Dr. George W. Palmer of Chelsea, with perforation and abscess pointing in the femoral region, there were extensive superficial ulcers in the colon, altogether different from those in amebic cases. Perhaps some of the dysenteric cases reported in Michigan belong to the specific bacillary form, the relations of which have been so admirably worked up by Dr. Flexner, but the existing reports do not enable one to be certain of that.

THE DIAGNOSIS.

Although the *Ameba coli* is a very striking object in its characteristic motion, those who have not seen it are likely to mistake for it various kinds of cells in stools. A number of these have been shown me in my laboratory by otherwise competent microscopists. The most puzzling things for the inexperienced observer are large epithelioid cells with violent protoplasmic motion in the body and with consequent movements in the sides. If one waits for the occurrence of true ameboid motion before making a diagnosis all such errors can easily be avoided, and if the stools are examined fresh, or what is often better, material obtained by passing a rectal tube, and the bits of mucus picked out, amebæ can easily be found if they are present.

HISTORY OF AMEBIC INVESTIGATION.

The finding of such a case as the one now reported recalls many interesting facts in the history of dysentery and of the amebæ found in stools. Although amebic dysentery was early looked upon as the dysentery of the tropics, largely owing to Kartulis' epoch-making observations and the striking relation of amebæ to "tropical" liver abscesses, it could not be forgotten that the parasites were first recognized in St. Petersburg (aside from the less important observations of Lambl, Lewis and Cunningham), and in chronic dysentery. I claimed, in a paper accepted for publication in October, 1890, but not printed until the next year, that ameba coli was probably a parasite having a world-wide distribution. The anatomic investigations of Councilman and Lafleur, the most important in many respects hitherto made in intestinal disease, and the discovery of the ameba in such different parts of the country as Baltimore, Texas, Philadelphia, Cincinnati, Chicago, Boston, Cleveland and Atlanta tended to fix the anatomic and geographic, as well as the clinical features of the disease. Owing to the difficulties in the way of assigning the exact etiologic relations of the amebæ, the observations just mentioned would have been of less value had it not been for discoveries in acute dysentery, both in and outside the tropics. The observations in these cases began as early as the most important ones in amebic dysentery, and culminating in the demonstrations of Shiga and Flexner, distinguish a very important group of cases, and enable us to study more accurately the nature of diseases belonging to the class of dysentery wherever found. At the same time, they have not lessened the diagnostic importance of *Ameba coli* nor made the need of further study of that parasite less imperative. On the contrary, they throw in a stronger light the close relation of the animal parasite to certain widespread, clinically important, and therapeutically difficult intestinal diseases. We must still learn the exact relation of the ameba coli to dysentery and intestinal ulceration, not to mention the remoter complications in the liver and thoracic organs. We can not as yet say whether the amebæ begin the anatomic alterations by themselves, or in association with bacteria introduced or normally living in the intestine, or whether they are nosoparasites, finding favorable seats for growth in lesions caused by other germs. That their association is purely accidental becomes less and less probable with the accumulation of data regarding the peculiarities of the intestinal changes. Direct and unequivocal proof, as by inoculation, is still lacking, and, from the difficulties in the way of cultivating amebæ, seems almost impossible. The results following the injection of material containing amebæ into the rectums of animals are not free from sources of error and have been contradictory in the hands of various investigators. The most important results are those of Dr. H. F. Harris, and, though they require confirmation, they deserve more attention than has hitherto been paid them. Harris[1] cultivated all the bacteria from dysenteric stools, but though he was unable to produce proctitis or colitis by injecting the cultures in animals, he succeeded (in young dogs) with the stools containing amebæ, even causing liver abscess, with amebæ. However, these experiments were few, and in view of the fact that Gasser produced colitis in cats by injections of garden earth, Sorgo with non-amebic dysenteric dejections, and also the fact that the previous observers have usually produced lesions not identical with those in human amebic enteritis, we must await further observations.

OPINIONS OF AUTHORS ON THE AMEBA.

The occurrence of amebæ in the stools of persons apparently well, or in those of patients with cholera or other diseases, or in the feces of lower animals, can not be considered proof that the amebæ found in dysentery have no pathogenic relation. I published an observation in 1891 showing the presence of severe ulceration in the cecum, with amebæ, in a patient without history of dysentery and with normal stools. Kruse and Pasquale pointed out very early that it was not necessary to assume the existence of two varieties, pathogenic and non-pathogenic, since the differences observed might be due to variations of disposition on the part of the host. On the other hand, our imperfect knowledge of amebæ in general, and the difficulties of distinguishing species or varieties make it highly probable that there are different kinds with different pathogenic characters.

Observations showing the occurrence of amebæ in healthy men have been much used, as mentioned above, to disprove the possible causal relation of amebæ coli, and those of Schuberg have been reiterated over and over again, and often as if they were typical of the conditions in all parts of the world. Schuberg, in brief, gave laxatives to persons without evidences of intestinal diseases. In the examination of "about twenty stools," he found amebæ in "about the half," "sometimes in tolerable numbers." He thought it "probable that amebæ (and flagellates, which he also found in his cases) occur as commensals in the human intestine extraordinarily frequently if not regularly."

---

[1] Virchow's Archiv. Bd. 166, p. 67.

In the first place, it may be remarked that Schuberg's conclusions hardly fit his observations; in the second place, that even if a certain parasite occurred in every case in one locality, it would not follow that the same parasite would also be found as widespread elsewhere. The observations of many early workers were opposed to those of Schuberg, also many later investigations, such as those of Janowski in Warsaw and Strong in Manila. The latter found amebæ in only eight out of two hundred cases treated with Carlsbad salts. The most recent investigator in this field, Zorn[2] in Munich, also had negative results.

My own early control observations were so different from Schuberg's[3] that at once after reading his article I began some investigations, giving Carlsbad salts in dose of one-half to one ounce, to all patients who had no contra-indication, and examining the stools as soon after they were passed as possible. More than two hundred such cases were examined, when I discontinued the routine examinations, but I have since then examined many other cases in the same way. In no case, except the one now reported and another to be mentioned below, were amebæ found. Flagellates, such as Schuberg also found in his small series of cases, I found six times in the first two hundred cases, and several times since then, but only in cases of diarrhea, never in persons with previously normal stools.

The exceptional case was one of ulcerated cancer of the rectum with diarrhea. On two occasions amebæ were found in the stools. The parasites were smaller than those I had previously seen in dysentery in Texas, the largest measuring 20 mm.; they contained no red blood corpuscles and, in fact, very few inclusions of any kind. They had a more marked tendency to travel in one direction than is common in ameba coli, and less ameboid motion.

From these observations I think it can be assumed that amebæ are not present in "about one-half" of all normal intestines, in all parts of the world. The determination of the intestinal fauna in various localities may aid in clearing up the etiology of intestinal disease and its comparative neglect is difficult to explain.

But, admitting that there are different varieties of amebæ that may infest the intestine, the question remains to be answered whether they can be distinguished other than by the effects of inoculation in animals which, as we have seen, are not altogether conclusive.

NOMENCLATURE OF VARIETIES OF AMEBAE.

The difference in size of the amebæ in my case of cancer of the rectum as compared with those in dysentery is very striking, but in other cases the matter of size has not been so easy to use. In the literature there are certain contradictory observations and the subject has been still further confused by premature efforts at nomenclature. Future investigators should avoid adding to this, but should endeavor to clear up the present contradictions. When Loesch gave the name *Ameba coli* to the organism he found he did not define the specific characters with sufficient fullness, though he did as well as the existing knowledge of protozoa permitted. Councilman and Lafleur, in giving a new name, *Ameba dysenteriæ,* without adding to the zoologic knowledge of the parasite, hardly realized the needlessness of such an innovation. The fact that so eminent an authority in zoology as Blanchard had already suggested still another name, *Ameba intestinalis,* also without greater definiteness, was an unfortunate example, but not a justification. Quincke and Roos attempted a more scientific nomenclature when they made three varieties of intestinal amebæ, *Ameba coli Loesch, sive felis,* characterized by being pathogenic for man and cats, *A. coli mitis,* mildly pathogenic for men but not for cats, and *A. intestini vulgaris,* non-pathogenic. Unfortunately, there are discrepancies or contradictions between their further description of the different varieties and the descriptions of most other investigators. Quincke and Roos described *A. coli felis* as being small, 15-25 microns in diameter and without blood corpuscles. The size of the amebæ in dysentery varies considerably according to different observers: Kartulis, 12-30 microns; Lafleur, 6-35 microns; Osler, 10-20 microns; Kruse and Pasquale, 10-50 microns; Craig, 5-35 microns, most frequently 15-25 microns. Though large amebæ seem to have been more frequently noticed than small ones in tropical cases, this has not been uniformly so and some severe cases in temperate regions have shown small amebæ with red corpuscles, those found by Zorn in Munich (1 case) measuring 14-22 microns, or about the same size as in the Cicilian case of Quincke and Roos. One of the most recent, as well as one of the most competent students of dysentery, Strong, goes so far as to believe that small amebæ found in dysenteric cases are non-dysenteric, but in giving these the name *Ameba coli,* the larger forms that of *A. dysenteriæ,* he does not seem to have proved his right to act as a sponsor any more than did Roos.

The matter of inclusion of red blood corpuscles, which has been used as a partial diagnostic feature, is still somewhat uncertain. Roemer[4] thought the presence or absence of blood corpuscles accidental, depending on the presence of blood in the intestinal contents. Sorgo[5] saw the amebæ become free from blood corpuscles, though there was still blood in the stools, in cats. In my case of cancer with small amebæ, there were no blood-inclusions, but there was very little blood in the stools at that time. The point is one that should be capable of experimental proof, and may be of more value than it now seems.

In conclusion, I wish to add that in view of the rapid advances made in our knowledge of acute dysentery in the United States, largely by Flexner and his pupils, and the fundamental work done in chronic dysentery by Councilman and Lafleur, it seems as if the inviting field offered by the study of the amebic form should attract more workers in this country than has been the case.

DISCUSSION.

Dr. Thomas McCrae, Baltimore—The paper just read is of special interest in reference to the question asked in Baltimore whether or not amebic dysentery is traveling northward. Several years ago one of these cases was admitted in Dr. Osler's ward, the patient never having been out of the state of Maryland and at that time this was contrary to the opinion expressed that practically all cases came from further south. Since then, however, there have appeared many cases that have never been out of the state of Maryland, where the disease is not infrequent. A point of especial interest, recently observed, is that an increasing number of cases are to be found in children and it has been found that some of these have occurred in children who have become infected through drinking "gutter-water." The report made by Dr. Dock has been of special interest as going to prove the wider distribution of the disease in the north.

[5] Wiener klin. Wochenschrift, 1897, No. 18

Dr. James J. Walsh, New York—During the past year at least two cases of true amebic dysentery have been reported in New York City. One of the patients had not been outside of New York City for years, the other had never been out of the city. It seems, therefore, that the ameba has crept as far north in its endemicity as New York City.

Dr. E. Libman, New York—At Mt. Sinai Hospital we have encountered a large number of cases of amebic liver abscess. During the past three years we have examined specimens from at last ten cases of this kind in which no history could be obtained of any residence outside of New York City.

Dr. Dock, in closing—I should have mentioned in my report that I excluded any possibility of infection from soldiers who returned from Cuba or the Philippines. Since the Cuban war there have been a number of cases of tropical infections from returned soldiers. In view of the wide spread of the disease, the vague symptoms that are present and the absence of the symptoms known as dysenteric, it is very important that all stools be examined more carefully than they have been in the past. Finding the organisms early gives a better basis for making a prognosis than anything else.

WHAT CASES OF PLACENTA PREVIA CAN BE BEST TREATED BY CESAREAN SECTION?*

FRANCIS D. DONOGHUE, M.D.
INSTRUCTOR IN CLINICAL SURGERY, TUFTS MEDICAL SCHOOL.
BOSTON.

It is not my intention to go over the whole subject of placenta previa and the various methods of treatment, because this has been done so thoroughly in the past two years as to be unnecessary. It is worthy of remark, however, that the importance of this condition has been forcibly brought home to the profession by the advocates of Cesarean section, and the treatment of this serious condition has taken on new interest.

At the time when I reported[1] the first entirely successful Saenger-Cesarean section for placenta previa there was little on record of value regarding the frequency and mortality in the various forms of this complication. At that time I had delivered but one case with placenta previa, and that only partial, in which rupture of the membranes allowed the head to engage, and mother and child survived, but I had in mind other cases with less happy results. All the statistics, however, that were available emphasized the serious nature of certain forms of placenta previa. The study made at that time of the literature bore out the statement made "that this was the most fatal complication with which the obstetrician had to deal, and under the most favorable conditions (meaning by that the results of well-conducted lying-in-hospitals) and in the hands of experts, showed a higher death rate, fetal and maternal, than almost any other obstetrical condition." The statistics, it is true, as later writers[2] have stated, were old, but the obstetric teaching in regard to this subject was no more modern, at least, so far as treatment was concerned.

It is not necessary to go over the entire ground on which the resort to Cesarean section in certain cases was held justifiable, but a review of those indications in the light of subsequent additions to our knowledge of the subject, will be of interest.

The indications appeared to be as follows:

1. Cases of complete previa.
2. Cases of *previa in primiparæ* when signs of *fetal* or maternal exhaustion are evident.
3. When the condition of rigid os is present.
4. Where there is a history of previous operative delivery.
5. In transverse positions and in cases of prolapsed cord, if the cord is not easily returnable.

Advocating section for these conditions is far from advocating section for all cases of placenta previa, as my paper has been quoted. We should not proceed too fast in the advocacy of new treatment, and while the surgical invasion of the obstetric field has only begun, I do not believe that section will be accepted as a cure for all obstetric complications until we admit that the pains of normal labor should be accepted as indications for interference.

The paper read by Dr. Gillette[3] at the meeting last year was a notable contribution to our knowledge of this subject, and his statistics of mortalities show that the condition is still a serious one. His report of the results of 216 cases in the hands of various men show 34 mothers lost, or a death rate of 15 1/3 per cent., and 96 children, or 44 1/3 per cent. As to the variety of implantation, there were 88 cases of centralis, 20 mothers lost (22 8/11 per cent.): while 66 children were lost (70.5 per cent.). Of the other forms of implantation (partialis and marginalis), 128 were reported, with 14 deaths for the mothers, a death rate of 11 per cent., and 41 of the children, or a death rate of 31.5 per cent.

Shauta[4] in a recent article, while arguing against section, gives the following figures: Placenta previa centralis, 50 cases, with the death of 9 mothers (18 per cent.), and 35 children (70 per cent.), while in 184 cases of partial previa he lost 7 mothers (3.8 per cent.), and 92 children (50 per cent.). These statistics do not differ from those quoted in my original paper, of Jardine,[5] who (1896-8) reported 12 complete, with 16 2/3 per cent. maternal deaths and 66 2/3 per cent. fetal, except that they are enough higher to prove that it is even more fatal than we originally believed.

In primiparæ this condition can not be said to be so rare as not to require consideration, as it occurs in about one in eight cases of previa. Fry[6] in reporting 14 cases, reports 7 cases in primiparæ.

Reason would seem to indicate that operative interference in primiparæ must be slower and more difficult than in multiparæ, because of the firmness of the parts.

It has been said, however, that the os with placenta previa is more easily dilated than if normal. This statement, however, should be changed, for there have been cases enough reported and evidence enough adduced in the past two years, to warrant the statement that the os is more easily torn than normally, while doing manual dilation and extraction; in fact, there are many cases of spontaneous rupture of the uterus in the presence of placenta previa.[7] [8]

Schultze,[9] in a discussion of uterine rupture, gives as a cause paralysis of the region of placental insertion. He refers to the fact that during pregnancy the uterine wall develops less in the portion where the placenta is attached than elsewhere, and that when the placenta is adherent, the portion of the uterine wall left after its separation is thin. Failure of this area to contract he terms paralysis of the area of placental insertion.

Anatomically no part of the uterus is more liable to rupture than the lower segment during labor, not only on account of the retraction of the muscular fibers of the uterus and the consequent thinning of the lower

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

segment, but to the causes of rupture as pointed out by Schultze. If spontaneous rupture is not uncommon, what may we expect with forcible dilatation and delivery?

The history of previous operative delivery in the case of a normal pregnancy has led men of great experience to advocate broadening the indication for section in cases with lesser degrees of pelvic contraction. The study of 1000 cases by Dobbins and Williams[10] shows most clearly the importance of a history of operative delivery in considering the treatment necessary in future pregnancies. These conclusions were: "that it is the border line of disproportion between fetal and pelvic diameter that we get the worst results for the fetus and it is the border line cases that are most frequent. First the fetus is shocked by severe forceps compression of the brain; then the heart is shocked by the manipulation of the cord necessary in version, and finally, if it still lives, it must run the gauntlet of asphyxiation." Admitting for the sake of discussion that many babies are small and not absolutely at full term, let me ask how a severe operative delivery helps a child already severely shocked and enfeebled?

In the past two years there is hardly a city in this country in which Cesarean section for some condition has not been performed, ranging from rigid os to eclampsia, and everyone is familiar with the ease and success of the operation. During the same time the number of craniotomies has grown steadily less, due not only to the improvement in surgery, but to the profession's awakened conscience.

When Dr. Ford[11] of St. Louis, in 1892, advocated Cesarean section in certain cases, on purely theoretical grounds, he did so when the death rate from most abdominal operations was still very high, but he was convinced that the do-nothing or the uncertain and indefinite methods then in use might be well superseded, in a large number of cases, by an operation which even then was promising the brilliant results it has since obtained. The most important point on which a resort to section was based was the fact, that we have to deal with two patients, and our whole duty is not conscienciously performed if we deliberately sacrifice or neglect the interests of the one in favor of the interests of the other. The discussions of the results obtained in the treatment of placenta previa which have been brought out in the past two years, are very important, for before that time the reports of large numbers of cases were few and in many instances combined old pre-antiseptic results with later ones, in such a manner as to be of little use in forming proper judgment.

What has been the sum total adduced by the advocates of no change from old methods? The gradual lowering of maternal mortality has been brought about by the sacrifice of larger and larger percentages of children. Fry[6] reported 14 cases treated as follows: Bi-polar version and slow extraction 9 times, membranes ruptured and delivery left to nature once, tampon and natural delivery once, forceps extractions 4, including one application after coming head. All of the mothers recovered and 5 out of the 15 infants were born alive. Of the infants lost, 2 (twins) were not viable; one, in fact, was at the seventh month of utero-gestation and 4 were dead when the case came under observation. The death of 3 infants occurred during delivery.

Let us consider his cases briefly, the kind of placenta with which he had to deal, as these cases are among the few that are recorded in a manner to permit study:

Case 1.—Edge of placenta felt, membranes ruptured, live child.

Case 2.—Placenta tissue felt, tampon, child dead.

Case 3.—Mass of placental tissue hanging down behind symphysis, delivered by forceps, child dead.

Case 4.—Primip., 5 months' pregnancy, twins, central placenta. Placenta perforated with finger, fetus seized and brought down. Fetus slowly extracted as far as the head, which was imprisoned by the undilated os. Traction made downwards and the skull opened with a pair of scissors; head collapsed and extracted. Second fetus found in utero treated in same manner.

Case 5.—Central placenta previa, tampon, followed by version. Dead infant slowly extracted.

Case 6.—Os slightly dilated, placenta felt; bipolar version. Slow extraction. Infant dead.

Case 7.—Primip., full term. Here no labor pains; placenta felt at os. Bipolar version. Infant extracted dead.

Case 8.—Placenta felt at os; 8 months' pregnancy. Infant extracted dead. Bipolar version.

Case 9.—Labor set in at term with eclampsia. Head presented with os dilated, placenta attached to left side. Forceps applied, dead infant delivered.

Case 10.—Placenta presenting. Bipolar version. Child extracted dead.

Case 11.—Placenta presenting. Bipolar version. Infant born alive but died next day.

Case 12.—Placenta felt at os. Bipolar version and extraction of a living child.

Case 13.—Placenta could be felt through os. Bipolar version and extraction of the after-coming head with forceps. Child recovered.

14. Placental mass in left side, head presenting. Forceps applied and living child extracted, which died next morning.

Two cases (1 and 14) edge of placenta felt, one delivery normal after rupture of membrane, one by forceps.

Ehrenfest,[12] in his paper on "The Impropriety of Cesarean Section in Placenta Previa, with Remarks on a Rational Method of Treatment," the major portion of whose bibliography is later than 1898, arrives at the following conclusions: "Saving the child's life should be one of the main tasks of the obstetrician, but it must not be forgotten that there is an indisputable rule that the mother's life ought to be valued higher than the child's. We can not deny that the excellent results of the modern treatment of placenta previa have been gained only at the expense of fetal life. We can not deny that the result of this treatment in regard to fetal mortality is very unsatisfactory."

Dr. Harris[13] at the Pan-American Medical Congress reported nine cases treated by rapid manual dilation, followed by delivery, with only three children saved.

Zinke[14] gives his fetal mortality in placenta previa in 40 cases as 55 per cent., but he does not give an analysis of the position of the placenta.

Stetson,[15] in his report of 1000 labors, gives the results of the treatment of five cases of placenta previa, as follows:

Case 1.—Complete. Ergot, full doses. Rapid dilatation; version; forceps.

Case 2.—Partial previa. Dilation; version. Child dead.

Case 3.—Partial previa. Dilation; version. Forceps.

Case 4.—Placenta covered os. Dilation; version; forceps.

Case 5.—Six months' pregnancy. Child dead.

These are not cases selected to prove or disprove any position, but are the most recent of published American results. If necessary to take figures obtained under the very best hospital conditions abroad, to prove that in the hands of the most skilful, the child can expect little, let us take the figures of Shauta,[4] given under date of Feb. 26, 1902, and we find little change from those already given. He says: "The fetal mortality with our present treatment is a high one because we treat expectantly and refuse to perform immediate extraction as a procedure dangerous to the mother."

Out of 234 cases of placenta previa, 127 children were lost, a percentage of 54. There were 35 deaths in children in the 50 cases of placenta previa centralis, 70 per cent., leaving 92 cases of placenta previa of varied types (excluding placenta previa centralis), 50 per cent. mortality.

The question we should put to ourselves in dealing with placenta previa is this: Are we justified in advocating and performing an operation which may have a slightly higher death rate for the mother, but which offers 95 chances in 100, at least, to a fetus alive at time of operation?

The profession in this country certainly have answered this, and have answered it affirmatively in substituting Cesarean section for craniotomy and premature delivery in cases of pelvic obstructions. both of which procedures have an extremely low maternal mortality, but a very high fetal. And again, how many of our practitioners are willing to uphold Leopold[16] when he says: "In private practice, owing to unfavorable surroundings, craniotomy, in contracted pelvis, is preferable to Cesarean section." When the fetal heart is weak he perforates.

The unfavorable surroundings in private practice, of which Leopold complains. are not looked on in this country as contra-indicating conservative midwifery, and it is by reasoning on conditions prevailing abroad that the opponents of Cesarean section for any form of placenta previa in this country make their greatest mistake. Then, by giving us the statistics and results of hospital cases in expert hands, they so minimize the danger, to the student, that every graduate in medicine looks upon himself as competent to treat any case of placenta previa in private practice, until some frightful experience teaches him differently.

If the success of American midwifery is not a sufficient refutation of the treatment proposed by Leopold, think over in your minds the thousands of successful capital operations which have been performed in private houses. for every conceivable condition, before deciding that section in private practice is not justifiable.

Has the child a right to its life? This has been so thoroughly considered in years gone by, in discussing craniotomy, that it hardly seems necessary to discuss it again, but if the child has a right which forbids the direct taking of its life, "is there anything but a difference in degree between perforating the head, an operation which we know will destroy the child and in performing an operation which of itself will result in the loss of one-half to four-fifths of the children."

Williams[17] says, in discussing contracted pelvis: "If we are operating solely in the interests of the mother, induction of labor appears to be a very excellent operation, but under the circumstances, why not do abortion at a much earlier period, and save all the weary months of pregnancy?"

We may well ask, to what would such a process of reasoning lead if accepted? It is urged that a large proportion of these children are not at full term; that may be so, but in over 90 per cent. of reported cases the child has lived in utero beyond the period at which it is viable, and all the children delivered by Cesarean section in the presence of placenta previa since 1899 have been delivered alive and have lived a certain length of time afterwards, as follows:

Tait;[18] child lived one *month*, dying of bronchitis. (Porro.)
Donoghue;[1, 19] 2, 1900, both alive. (June, 1902.) (Sanger.)
Hare;[20] 13 days, inanition. (Sanger.)
Gillette;[21] 1, alive. (Porro.)
Covington;[22] 1, alive. (Sanger.)
MacCalla;[23] 1, alive. (Porro.)
Matolli;[24] who did Cesarean section after trying to pack vagina, lost child. (Sanger.)

The resort to a Porro I do not believe to be indicated in a case of previa, unless otherwise complicated, any more than it is in cases of contracted pelvis.

Andrews,[25] in summarizing his paper on "Cesarean Section vs. Craniotomy," says: "I will say that craniotomy on the living fetus is very, very rarely justifiable, unless the choice of the mother to sacrifice the life of her unborn child, rather than subject her own life to a slight risk, renders it justifiable." If the mother has, in cases like placenta previa, or pelvic obstruction, the right to decide what treatment the attending physician shall employ, to the end that she shall not then be exposed to any danger, that her child may live, or shall have the right to demand an operation (Porro) that she may not again be exposed to the dangers of pregnancy, why has she not the same right to decide that any given pregnancy may be attended with more danger than she desires to risk, and call for its termination at any time she may elect? How many of the profession are willing to act as passive agents in carrying out such treatment?

The failure of the uterus to contract does not seem to be a good indication for a Porro. I believe that many cases of excessive hemorrhage will disappear if the operation is not performed with one eye on the time and the other on the field of operation.

In my cases. after removing the child from the uterus, I have waited and allowed the uterus the same time to contract and retract that I would allow if conducting a normal delivery. This I believe to be very important, and if, as in some cases, there seems to be danger from the loss of a small amount of blood, I would free one edge of the placenta, put a gauze wick through into the vagina and close uterus and abdomen, leaving placenta to separate later. The danger of ventral hernia following operation does not seem to be important if the incision is made through the rectus muscle and properly closed.

CONCLUSIONS.

Cesarean section in certain cases of placenta previa has a fairly well-defined standing; its limits can not as yet be accurately defined. At present it seems that the conservative Sanger should be performed in cases of:

1. Complete previa.
2. Previa in primiparæ in the presence of severe hemorrhage or a rigid os.
3. Where there is a history of previous operative delivery.
4. It should be considered in all cases of placenta previa where version is indicated if a reasonably skilled *surgeon is available*, and only an ordinary obstetrician.
5. All of these indications are based upon a probable viable child, 28 weeks of gestation and upward.

When the pendulum swings from the excessive amount of surgery taught in the medical school, to the proper teaching of obstetrics it may be necessary to revise these indications. While, aside from this, a man, as soon as he becomes an expert obstetrician, finds it to his advantage to gradually work into something better, for, as Dr. Price has expressed it, "There has never been a premium on practical obstetrics."

DISCUSSION.

Dr. Rudolph W. Holmes, Chicago—I have dabbled in statistics, and I am positive that they are of only relative value unless they demonstrate the results of one body of men in a large hospital service; the gathering of case results from promiscuous sources never can give positive criteria to found a working hypothesis; seldom does a man report a fatal termination unless there be unique features about the case. In placenta previa statistics are absolutely worthless as regards mortality or method of treatment unless there be a clear differentiation between the several types of previa—the lateral, partial and central. The mortality of lateral previa is low; speaking very broadly, it is exceptional for lateral previa to terminate fatally, only when the type approaches the marginal form does its portent become more grave. Central previa, on the other hand, is always potentially very serious. In lateral previa it is not possible to lay down positive rules of conduct—often more or less temporizing measures will secure favorable results; more drastic procedures are reserved for special indications. In the central previa we may lay down very clear and positive principles which will answer for nearly all cases, but the treatment is always an active one. At this time I think it is a most pernicious teaching to advocate Cesarean section in central previa; it is a continuation of that *furor operativus* which so held the gynecologist some ten years ago. The first thing to do is to develop the treatment of placenta previa for the average man. When he knows that, then we can begin to talk of Cesarean section in selected cases, but as yet we do not know the possibilities of the obstetric treatment. To-day, perhaps, the most faulty treatment for placenta previa is the tampon, but for the general practitioner, the man with little or no obstetric technic, a well-applied tampon will give him the best results. I would be distinctly understood that I do not advocate the tampon for the obstetrician, but for the practitioner who has not the skill acquired by practice in operative obstetrics, or an adequate obstetric armamentarium at hand: teach students how to build a proper tampon, and much of its ignominy will disappear.

The best results of the future in central previa will come from the timely introduction of the colpeurynter, followed by internal version, or an early Braxton Hicks version. The cardinal principle should be to perform version as rapidly as is consistently possible, and to make the extraction as slowly as possible. Rapid extraction is the explanation of many a death from deep cervical laceration, and is the explanation of many a so-called rigid os—both being dependent on extraction before dilatation was complete. The high mortality of previa is due to hemorrhage and infection; the treatment as outlined above will do away with many deaths due to the former, and a proper application of asepsis will entirely eradicate the second. The possibilities of the future are well exemplified in the recent figures of De Lee, who reports 31 consecutive cases with one death, and this one death was a neglected midwife case.

It is a most egregious error to compare the percentage mortality of Cesarean section as usually given for the operation done on pelvic indications with the fatality when done for placenta previa. The usual figures, 5 per cent., mean results in selected, uncomplicated cases. Combining favorable and unfavorable cases together will still show a mortality of nearly 20 per cent. in Cesarean section; this latter figure was given me a short time ago as the mortality in the Ohlshausen clinic by one of his assistants. The fact is that the specialist rarely receives placenta previa cases first hand; the general practitioner gets them, wastes valuable time, and finally sends for the obstetrician, who must then do the section, if this new teaching is to be adopted. I would lay stress that the time never will come when the Cesarean operation in placenta previa will mean an uncomplicated case; it always will be an unfavorable indication for section. He who will compare the operation done on pelvic indication with that for placenta previa, he who will declare the mortality of previa treated obstetrically is 20 or 25 per cent., and surgically only 5 per cent., is dealing with the worst kind of sophistry. After the operation the woman still will be subjected to the dangers of post-partum hemorrhage—it will be necessary to tampon the uterus, which can not be effectively done through the uterine incision, so the only course to pursue will be to do an hysterectomy. Cesarean section for placenta previa should only be permissible in contracted pelves, and placing the relative indications somewhat higher than usual, and in old cicatricial contractions of the parturient canal where extraction would be hazardous. I agree that Cesarean section when done early will save more babies, but so long as 10 per cent. of babies born alive die within the first twenty-four hours, so long as nearly 25 per cent. die within the year, and 52 per cent. before fifteen, I claim the woman's life is worth more than the baby's, and her chances should receive the first consideration.

Dr. G. T. Harrison, New York—I would like to raise my voice against the use of any such operative interference as that for the treatment of placenta previa. The principal thing is to save the life of the mother; the child is a secondary consideration. All efforts should be extended to save both, but if the interests of one must be weighed with those of the other, the mother's interests should be considered first. I have the same opinion of statistics as Dr. Holmes. I recollect very well the witty remark made by Dr. Sims years ago when arriving at statistics on ovariotomy. He said: "My young friend had 100 per cent. of recoveries." "How is that?" said somebody. "Why he had only one case, and that got well." That was only a witticism, but there is a great deal of truth in it. Statistics can not be relied upon. A very good point was made by Dr. Holmes when he said that a Cesarean section is absolutely contraindicated when the patient has been examined, and when there is any fear of infection. In the greater number of cases you can fear infection, especially if the ordinary practitioner of medicine has examined the patient beforehand. I would not dream of performing a Cesarean section if the case had been examined before, unless it was an expert who did it.

The main thing that should catch our attention is that our efforts should be directed to diminishing the frightful mortality of the child, and I think experience has fully demonstrated that in treating these cases by slow extraction after a Baudelocque version, that if we ignore the child and consider only the mother, we will save more children and more mothers. We ought to save all the mothers, and by proper precautions we can. I have had a large experience with placenta previa, but I have never lost a mother, so that my statistics are very satisfactory. A large per cent. of the babies died. Of course, the great danger in these cases is the danger of infection, but that is largely eliminated by present methods.

The reader of the paper intimated that even when the head came down, danger from hemorrhage was to be considered. In all cases when the head comes down it stops the bleeding by acting as a plug. In those cases you have no trouble in the way of hemorrhage, and you can wait for dilatation, and when you put on the forceps it is just as easy as any other case.

Dr. Hugo Ehrenfest, St. Louis—In discussing this subject, some mention was made that the time was approaching when Cesarean section would be the only proper treatment in placenta previa. Another gentleman said it would be the school treatment of placenta previa. To-day the indication is rather limited, but not limited enough. It should be that no conservative Cesarean section be made in a patient who has been examined by someone who has not been clean.

Another question is how to make a diagnosis of placenta centralis in time. If the cervix is open enough to admit two fingers, we must make version or Cesarean section. We are not able to decide whether we have to deal with placenta previa centralis or partialis, in which case the hemorrhage stops immediately when the head comes down. I do not compare the statistics of Cesarean section and placenta previa, because that can not be done. We ought to have statistics of both. Cesarean section in selected cases gives us some very good statistics.

Dr. Donoghue, in closing—Any general practitioner who is competent to pack a vagina properly is also competent to do a Cesarean section, because his asepsis must be complete in either case. The second speaker spoke of no hemorrhage after rupture of membranes in partial previas. I expressly said that in that class of cases Cesarean section was not indicated, and it should never be used. It is a self-evident fact that rupture of the membranes allows the head to come down and forceps can be used. My advocacy of Cesarean section is based on a belief that the child has an undeniable right to life, which should be preserved to it, if possible. To go over the other points which have been mentioned in the discussion would simply be repeating the arguments of the paper just read.

TREATMENT OF TUBERCULAR PERITONITIS.

(Continuation from page 604 of the discussion on the paper of Dr. Porter.)

The postmortem examination was made by Dr. Fütterer, *one-half hour after death. General abdominal tuberculosis* of the ascitic variety and slightly enlarged mesentery glands and firm adhesions matting together the whole mass of intestines, was found. No foci were found in the lungs or pleura. There was no old tubercular disease of the tubes. The intestinal mucous membrane was not examined.

Cultures from the peritoneal cavity were sterile and there was no pus infection of the peritoneum.

The points of interest in this case are: 1. The insidious onset of the disease. 2. The persistence of normal temperature. 3. Extreme pigmentation of the skin without Addison's disease. 4. The presence of a tumor in the median line of the abdomen extending from above the umbilicus to the pubis; and the tumor being formed by the greater omentum becoming rolled on itself and filled with fluid. 5. The termination of the case, death following thirty-six hours after the operation with symptoms of hemorrhagic diathesis. This was probably due to a toxemia of some sort, the toxic substances probably being liberated as a result of the changes which occurred consequent on operation.

Case 2.—B. B. This patient was a young woman who was operated on for what was thought to be suppurative peritonitis following a rupture of the appendix. Her illness began suddenly with a chill and severe abdominal pain, which in the course of a few hours became localized in the region of the appendix. The temperature was high, ranging from 103 F. from the first. The abdomen soon became greatly distended, with marked rigidity of the abdominal muscles.

Operation.—The abdomen was opened through an incision along the outer border of the right rectus muscle, on the third day after the onset of the disease. The peritoneal cavity contained a large quantity of turbid fluid, the walls of the appendix and cecum were greatly thickened, but no rupture occurred. The entire peritoneum was thickly studded with tubercles and dense adhesions binding together the intestinal coils. The mesenteric glands were enlarged, some reaching the size of an English walnut. The appendix was removed, the cavity irrigated with salt solution and drained by tubular and gauze drainage.

The patient made a very slow recovery, leaving her bed only at the end of three months. As soon as she was able to travel, she was sent to Colorado. She remained there for two years and completely regained her health. At the time she left her bed, she weighed about eighty-five pounds. When she returned to this city after an absence of two years, she had gained fifty-five pounds in weight.

As a result of the operation she had a ventral hernia for which she was operated on in the summer of 1899, three years after the first operation. In operating for the cure of hernia, the abdominal cavity was again opened. Careful inspection showed that scarcely a sign of the former extensive tubercular disease existed; all the tubercles had disappeared; the peritoneum was everywhere normal in appearance. Intestinal coils were nowhere adherent. The mesentery glands had mostly resumed the normal appearance. There were a few calcareous deposits to be seen here and there in the mesentery. These were surrounded by a wall of white fibrous tissue. Several of these deposits with surrounding fibrous tissue, were excised and submitted to a microscopic examination. No tubercle bacilli were found.

Since that time the patient has resided in this city and has been examined a number of times. There are no signs of tubercular disease in any part of the body. The interesting features of this case are: 1. The acute character of the disease, simulating closely acute appendicitis and the beginning of suppurative peritonitis at the time of operation. 2. Extensive abdominal tuberculosis, a part of which must have existed previous to the onset of the symptoms, although the patient was apparently in perfect health. 3. The complete recovery from the disease, as was evidenced by the return of health and the disappearance of all tubercular lesions of the peritoneum.

Dr. Robert F. Weir, New York—This is a subject that interested the American Surgical Association last week and a good deal of liveliness was elicited in the discussion. If I were to get the opinion of all of you I think it would be something like this: It would be admitted that we do not know how the disease invades the peritoneal cavity, but we are able to decide that its infection comes partly through the genitalia in both sexes; we also know that the appendix occasionally gives rise to it, but in many instances we can not trace it at all. It will be also admitted that when a case presents itself to us where there is fluid in the valley we can decide usually and wisely decide on a distinct plan of treatment. The accumulation may be all over the abdominal cavity, while in some cases it is encysted. Occasionally we can treat these cases by waiting and get good results, but why do this? Why keep this child in whom the disease is most common waiting when puncture or, preferably, a small incision, is pre-eminently a safe procedure? In reference to the influence of *light and air, it is not believed that this plays an important* part. I believe when a cure or improvement is effected the reason for it is to be found in the free invasion of the cavity, which means excision through the peritoneum, which brings about reflex circulatory change all over this largely extended membrane. When, however, one knows or finds by incision that no fluid is present or that matted intestines present themselves, it is best to hold one's hand. Even in such arrested operations I have ocasionally found good results show themselves, though this is the exception.

Dr. A. J. Ochsner, Chicago—In looking over my own cases carefully and reviewing the literature on this subject I have come to certain conclusions which, it seems to me, are worthy of application in our clinical work. In the first place it seems that there is a certain class of patients suffering from tubercular peritonitis in whom medical treatment is better than surgical. This should consist in rest in bed, hygienic surroundings, aseptic food, and possibly certain remedies such as creosote and iodin. This form of treatment will probably enable 50 per cent. of these cases to improve. This relates to cases suffering from acute tuberculous peritonitis with ascites. There are two reasons why the surgical treatment is not indicated: 1. They do get well without surgical interference. 2. It has been shown that in acute tuberculosis of the peritoneum, with ascites, the surgical treatment was not followed by permanent cure when the operation was performed before the tubercles were fully developed, and for this reason this class should be excluded. There is, therefore, one particular class in which the surgical treatment is absolutely indicated, which comprises those cases that are not benefited after the internal treatment outlined above has been faithfully tried for several weeks. If an acute case is treated by hygienic measures and internal remedies for some months we frequently find that certain portions of the peritoneal cavity will become separated by adhesions. Nature tries to dispose of the tuberculous infection in this matter. In these cases we have circumscribed areas filled with ascitic fluid usually bounded above by adhesions between the cecum, colon, small intestines and omentum, and below by the pelvic organs together with a portion of the sigmoid flexure, also forming a mass of adhesions. The improvement under medical treatment continues to this point and then it ceases, and the patient becomes weaker and weaker and finally dies unless surgical treatment is instituted. It is not wise in these cases to remove the infected portions. If the abdominal cavity is simply opened and drained, the tuberculous tissue will be absorbed in about 50 per cent. of this class of cases. I recall some cases, which I reported recently, in which the pelvis was so completely filled with this tuberculous material that the condition seemed absolutely hopeless, and still simple drainage brought about recovery sufficient to make a subsequent normal pregnancy and childbirth possible. There are many other things of great practical importance I might mention, such as caseation of the tuberculous material and adhesions between loops of intestines. If these areas are disturbed during the operation intestinal fistulæ will follow, while if they are simply left to nature they are likely to clear up and leave nearly normal conditions. As to the after-treatment, I would say that the same principle applies to these patients who have recovered from tuberculous peritonitis that should be borne in mind in the after-treatment of patients who have recovered from localized tuberculosis in any other part of the body. Either the patient has swallowed tuberculous food or has tuberculosis of the lungs or he is living in unhygienic surroundings. In order to remove the possibility of reinfection, the conditions which existed primarily and were responsible for the original infection, should be removed. The patient should be placed in good hygienic surroundings. His diet should be properly chosen. He should receive tonic and antitubercular treatment for a considerable time after recovering from the tuberculous peritonitis.

Dr. Ernest Laplace, Philadelphia—The tubercle bacillus is an organism of low vitality but of remarkable persistence, and the reaction to its growth is a slow development of tissue. There are two kinds of tuberculosis: pure cultures of tuberculosis, and secondary infected areas of tuberculosis; and it matters much whether we are dealing with the pure condition or a contaminated one. As a result, typical cases of tuberculosis are almost always infected by other germs. Tuberculosis of itself tends to get well; we have this often exemplified especially in the lungs. The tubercle bacillus will die if you give it a slight incentive. Being a pure infection, it only asks a slight degree of irritation to absent itself and it is cured easily by adhesive inflammation. Take the laboratory view of these cases, for instance, the tubercle bacillus will die if the slightest abnormal conditions are applied to it. If you put it in a place where the alterations in temperature are extensive, it will surely die. All you need to do is to alter the nature of the soil in order to cure tuberculosis. Hence the counter irritation of the air, and the counter irritation of the operation, tend to destroy and cure the local tuberculosis.

Dr. A. H. Ferguson, Chicago—Out of 15 cases of tubercular peritonitis, where I opened the abdomen, 12 were benefited, 2 were cured, and 1 died under anesthetic. As to those that got better, one was a girl of fourteen years, with an enlarged liver and ascites. I suspected hydatids before I opened the abdomen. The liver surface was studded with tubercles, as were the bowels. I closed the abdomen and left the fluid there, the little girl making a beautiful recovery. She has since had four children and is in good health to day. The other case that I shall mention was just at the other end of tubercular disease. She had gone through all its stages which first involved the uterus and tubes and ovaries and these were removed. Tuberculosis of the intestines then followed and caused chronic obstruction of the bowels, which were found all matted together. I removed considerable of the small bowel and four or five inches of large bowel and made an end-to-end anastomosis of each. The woman made a perfect recovery, gaining over forty pounds and is in perfect health to-day. The first case was no doubt helped by the antiseptic quality of the blood itself. I agree with the opinions expressed by Dr. Weir.

Dr. Robert Reyburn, Washington, D. C.—I remember the case of a boy 17 years old who had tuberculosis of the right lung. Later he developed an inflammation of the peritoneum, and when I saw him he evidently had had an effusion into the peritoneum. Although I believe in doing very little in these cases, I decided to operate on him. I made a simple incision, washed out with a solution of boric acid and introduced a tube for twenty-four hours, withdrawing over two quarts of purulent material. The question is, how are these patients cured? It sometimes seems ridiculous that after simply opening the abdomen the patient is cured, but I believe it is due to the bactericidal power of the abdominal fluids. They seem to be able to take care of a moderate amount of poisonous products themselves. When we open the abdomen and wash out the abdominal cavity, the bactericidal power of the blood serum itself does the work and there are so many cases of this kind reported that it does seem to me to be one of the most admirable things in surgery.

Dr. Rufus B. Hall, Cincinnati—My experience does not correspond with some of the previous speakers in reference to patients suffering from chronic tuberculosis. In all these cases where we have a localized abscess, especially in the lower half of the abdomen and pelvis, or at least in a large percentage of them, the nidus of infection is in the Fallopian tube, while in a small percentage it is in the appendix. In all cases where the tube is the seat of abscess, I think the correct procedure is the removal of the tube and not drainage alone. My experience is that drainage is the correct treatment afterwards, but whether it should be vaginal or abdominal, must be settled in each individual case at the time. In all cases operated on where there is pus, I think it better to drain. My ultimate results have been much more favorable than Dr. Ferguson's. More than 50 per cent. of all cases operated on have recovered and have remained well long after the operation. Of course, some die following the operation and in others meningeal tuberculosis develops, but these are the exceptions. Some cases of acute peritoneal tuberculosis will recover without drainage, although drainage does not hurt them.

Dr. Richard H. Gibbons, Scranton, Pa.—To be successful in the management of these cases we must use internal medication, such as iodoform and iron; guiacol and ichthyol. I fully agree with Dr. Weir and the other gentlemen who believe that light and air are not especially the means of cure in these cases as long as there are other means of the operation to be considered. It is owing to the large increase in the amount of blood to the parts after they have been freed from adhesions, and particularly after any extensive surgical procedure, that we are able to do good for tuberculosis in the peritoneal cavity. Dr. Joseph Price explores the abdomen thoroughly in every surgical operation performed by him in these cases, with a view of discovering peritoneal tuberculosis, and his method is to go into the cavity, dealing with all foci of infection, exposing the mesentery on both sides in every case. After opening these up, by making a free incision, he packs the cavities with iodoform. Gauze, of course, is used and the abdomen is thoroughly washed out with hot water. The tubes, ovaries and appendix should be removed, I believe. This is the most successful way to deal with tubercular peritonitis. When we get an almost inoperable case, it may be well to desist from further active surgical interference than a mere opening, but I doubt it. Dr. Agnew used to order iodoform and iron, but Trousseau condemned iron in lung tuberculosis. I think iron combined with iodoform goes a long way towards the curative effect on these cases, and the carbonated creosote may have a very large contributory influence towards a cure.

Dr. Porter, in closing—From the tone of the discussion it would seem that I had advocated the therapeutic power of light and air to the exclusion of other things, but I distinctly did not do this. The point I wanted to make was this: it is not the trauma alone that does the good, nor is it alone the relief of pressure. It seems to me there is unquestionable evidence to prove that no one cause can be assigned to explain the cure which results after operation in tuberculosis of the peritoneum. The other point I wanted to make is that a careful study of the literature of the subject had convinced me that there are many elements entering into the cure of each case. To be wise and fair, we must attach importance to all the elements and use common sense, which really is the only thing that enters into the technic of all medicine and surgery. In support of what I did say in reference to light and air, I would mention that these conditions probably do more good than is often ascribed to them. Dr. Laplace says that, if you do not keep these bacteria in the dark they will die, but it does not hurt them to lie in the light and air. These cases get well, but not because of tuberculous inflammation, nor is it because they are enclosed within walls of fibrous material. I agree with Dr. Hall and should certainly drain whenever mixed infection is present. Tubercular germs are not pus-producing germs. If you have pus you must have something besides tuberculosis.

THE ADVANTAGES OF THE VAGINAL OPERATION IN OBESE PATIENTS.*

W. H. HUMISTON, M.D.
CLEVELAND, OHIO.

The assurance and skill which an operator acquires by following in any one condition a certain method of operation and technic might be commended, provided all his cases approach an ideal. However, this is far from any one's experience.

The popularity of the vaginal route for hysterectomy which is steadily growing among American surgeons has not reached its height with me. However, I do find in certain cases the method to be, if not ideal, at least expedient. I refer particularly to those cases in which excessive deposits of adipose tissue throughout the body are a sure indication of lowered vitality and lessened power of resistance to shock and to sepsis.

My early experience with this class of cases was very unhappy, and I have welcomed the simplification of the technic of vaginal hysterectomy by a bi-section of the uterus as a fortunate advance in modern surgery.

ADVANTAGES MENTIONED.

I wish merely to emphasize the value of the vaginal operation in those cases where general physical conditions would make one hesitate to advise an abdominal section, and will leave the discussion (so far as the local conditions obtains and the technic of the original method) to others.

1. The length of time in which the patient is being subjected during an operation should always be considered as a factor against the employment of the unessential elements of technic. The longer the time of operation the greater the depression, the larger the amount of anesthetic, the longer exposure, the more handling of parts which must necessarily give an increased reflex action occasioning shock.

2. In thick belly walls the difficulty in which the pelvic organs are brought into the wound necessitates more or less bruising of the wall—a source of danger to infection. The poor blood supply of fatty tissue is another element of risk in the proper repair of a wound.

The contra-indications to any vaginal procedure excepting merely for drainage of an abscess cavity is the presence of adhesions above the brim of the pelvis.

REPORT OF CASE.

In the case which I am about to report, however, the general condition of the patient was such that notwithstanding the evidences of adhesions outside of the pelvis, hysterectomy was performed by the vaginal route with a very satisfactory recovery, whereas the result, I am sure, would have been disastrous had an attempt been made to remove the diseased organs through an incision in the abdominal wall.

History.—Mrs. E. S., aged 33 years, married for the second time, three years previous. She had given birth to three children, of whom the youngest was 15 years old. She had had no miscarriage nor puerperal fever following any of her confinements. When 23 years of age, she had diphtheria, and at 30 a severe attack of smallpox, her first husband and children dying of the latter disease. The early menstrual history is negative. After the birth of her second child she suffered greatly at times with dysmenorrhea, flowing at irregular intervals and usually in profuse quantity. Five years ago she had severe hemorrhages from the uterus and was curetted. She was entirely relieved for some months but gradually the conditions returned and she has been practically flowing now more, now less ever since.

In June of 1901 she was again curetted with temporary relief; since this last curettement she suffered intensely at times and noticed that a swelling in the lower part of the abdomen which she first discovered in 1900 was steadily developing. This, upon examination, however, proved to be only adipose tissue in the belly wall. The uterus was greatly increased in size and immovably fixed in retroversion—large inflamatory masses were found in each lateral vault of the vagina.

Operation.—On Feb. 10, 1902, after curetting and thoroughly disinfecting the whole uterine cavity, I proceeded to the removal of the uterus and its diseased appendages by vaginal hysterectomy—bisecting the uterus and applying clamps to the broad ligament.

The walls of the uterus were much thickened and fibrous, and there were double tubo-ovarian cysts or old abscesses with exceedingly dense adhesions to adjacent structures. Fingers of omentum and a coil of intestine were freed and returned to the abdominal cavity and the pelvis and vagina were packed with sterile gauze.

Six drams of chloroform were administered for a few minutes short of one hour. The time required for the hysterectomy was 35 minutes.

The clamps were removed in 48 hours and the last of the gauze in the pelvis on the eighth day. The patient was out of bed on the 22d day following her operation. The vault of the vagina being perfectly closed and seemingly firm.

This patient, whose height was 5 feet, 7 inches, weighed 281 pounds. She was extremely anemic and cachectic with a pulse of small volume, low tension, irregular and arrhythmic and averaging about 110 per minute.

At no time following the operation did I feel a bit anxious as to the outcome, and yet never did I have so unpromising a case.

DISCUSSION.

Dr. C. O. Thienhaus, *Milwaukee*—I am always in favor of the vaginal route because of the immediate and remote advantages of this route for the patient, not always for the surgeon, and am of the opinion that, what we can operate on by this route should be operated on by this route. What experts in this line of work are able to perform is shown, for instance, by the statistics of Duehrssen, who operated on thirty-six cases of extrauterine pregnancies ruptured and unruptured by vaginal anterior celiotomy without a death. He advocates this method for every case of extrauterine pregnancy up to the third month. Statistics of others show the same good results. Naturally, the individuality of the surgeon and the experience in this line of work plays a great rôle. Dr. Goldspohn challenged me the other day to show him the literature where Duehrssen cites only 2 per cent. of recurrences with his method of vaginal suspension. This is cited, as will be stated in my paper the day after to-morrow, in Duehrssen Zeile: 20 photographic plates for illustration of gynecologic operations, in special conservative colpo-celiotomy, Berlin, 1902, Kargers Verlag, page 17.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

Dr. J. H. Carstens, Detroit—I want to say, in defense of American operators, that we can show men here in this country who had thirty, forty and sixty cases without a death and they operated by the abdominal route.

Dr. J. Wesley Bovée, Washington, D. C.—I agree thoroughly with the author of this paper. I believe that the vaginal route is the proper route for this kind of work. It is the route for carcinoma when we intend to do a radical operation in but rare cases. In ruptured tubal pregnancy it is really a toss-up whether it is the preferable route or not. If adhesions, which are beneficial, in these cases, are present, and an accumulation of blood, etc., way down in the pelvis, we can take it out in this way, but if we have rupture with much blood in the peritoneal cavity, or perhaps a living fetus, with the sac, then the vaginal route is out of place, and the abdominal route is the only one to use. I had a case recently of ruptured tube, with a three and a half months' live fetus, much blood in the abdominal cavity, which I could not have discovered if I had gone through the vagina. We must not forget that there is a pelvic brim, and work above it can not be done through the vagina.

Dr. Seth C. Gordon, Portland, Me.—I do not believe Dr. Humiston voices the sentiment of the gynecologists of this country when he says that operations by vagina are increasing. I believe they are decreasing and very rapidly, too. The case he cited was one strictly for the vaginal operation, and I make this emphatic because I am satisfied that if I had adopted the same route in a similar case, I would have saved my patient.

Dr. Charles P. Noble, Philadelphia—I agree with Dr. Humiston that in fat patients the abdominal route presents many difficulties, but I do not believe for one moment that vaginal hysterectomy is on the increase, either in this country or in any other country. Some years ago Dr. Jacobs of Belgium came over here to teach us to do vaginal hysterectomy. He saw what good work was being done with the abdominal route and he is now the leading abdominal operator in Belgium. The same thing is true of Segond of Paris. So far as cancer is concerned, there is great reaction in Europe for the abdominal route.

As to the relative merits of these operations in extrauterine pregnancy, I have done about seventy-five typical operations and have had one death. This patient had both phthisis and nephritis. Of four cases I operated on from below, two had to be reoperated on from above. In one hydrosalpinx developed and in the other a tubal mole developed. One of our members had hemorrhage a number of times and had to go in from above, after having started from below. We are not going to gain anything by giving up the good thing we have in the abdominal operation for the uncertainty of the vaginal route.

Dr. Humiston, in closing—A few years ago I did nothing but the abdominal operation, and I considered I had a low mortality, but since I carefully selected the route applicable to each case, my mortality is still less. I make one vaginal hysterectomy where I make six abdominal hysterectomies. Judgment should be displayed in each case. I have not as yet lost a case of extrauterine pregnancy, and I have operated on every one from above. When the patient was in profound shock, I would resort to saline infusion the moment the anesthetic was started, and I have a *nil* mortality in extrauterine cases. Some of the histories of these cases are almost beyond belief. I have operated when the patient was pulseless, temperature as low as 94.5. Saline infusion was started the moment the operation began, the abdomen was opened rapidly, without waiting to clear away clots, but I put on the clamp, and when the operation was completed the patient was taken off the table with a pulse. You must individualize your cases, and sometimes you will do an occasional vaginal operation, but in the majority of cases your operation will be abdominal.

POST-OPERATIVE INTESTINAL PARESIS.*

FREDERICK HOLME WIGGIN, M.D.
NEW YORK CITY.

The convalescence of a person at the present time on whom an intra-abdominal operation has been performed is usually so peaceful a period that it is often hard to realize the grave dangers which surround the patient and which are liable suddenly to obtrude themselves and change the scene into a stormy and anxious one. Hence, the post-operative responsibility of the physician is great, for the safety of the patient depends on his ability to quickly recognize and successfully treat these complicating conditions as they arise. Of these complications the most frequent and probably the one least often recognized in its initial stage, when it is readily controlled and a fatal outcome avoided, is that form of intestinal obstruction due to failure of the muscular fibers of the intestines to contract, giving rise to an accumulation of the bowel contents in the paralyzed portions of the gut.

ETIOLOGY.

The trouble usually arises from injury of the intestinal nerve supply in the course of an intra-abdominal operation, and is especially liable to occur if the operation is prolonged and rendered difficult by reason of the distention of the bowel with gas. It is probable that the rapid and excessive development of gas which often follows laparotomy is due to defective or deranged innervation, as has been pointed out by Mr. J. W. Malcolm of London, rather than to fermentative and putrefactive processes, although these may be important factors in the production of the trouble. Adenot says that in a certain number of these cases the chief difficulty is due to pressure upon the left subcostal angle of the colon by the distended coils of small intestines; peritonitis and enteritis-thrombosis and embolism of branches of the mesenteric arteries or veins may also give rise to it.

SYMPTOMATOLOGY.

When the trouble is due to trauma of the intestinal nerves it first manifests itself by the continuance of the nausea which usually follows the administration of the anesthetic, therefore, if no morphia has been administered to the patient following the operation, and eighteen hours have elapsed since its conclusion, and she is more or less nauseated, having no desire for nourishment, or is regurgitating a quantity of straw-colored liquid from time to time, has passed no gas from the anus, is slightly tympanitic, the pulse rate weak and increasing in frequency, the bodily temperature slightly elevated while the respirations are normal, there is good reason for believing that the patient is suffering from intestinal paresis. If the course of the disease is not interfered with, the vomiting becomes more frequent, the amount of liquid ejected larger in quantity, its color gradually darkening till it finally becomes black, its odor seldom, however, becoming fecal in character; meanwhile the intestinal distention continues to increase, the pulse rate to rise and to lose in force, the body temperature slowly rising, while the respirations slightly increase in frequency. The course of the disease is rapid, a fatal termination usually being reached within forty-eight hours of the onset.

DIAGNOSIS.

From peritonitis the disorder may be differentiated by its earlier onset, by the character of the pulse, the frequency of the respiration and by the absence of pain and rigidity of the abdominal muscles. From intestinal obstruction due to adhesions or bands by its earlier onset, less urgent symptoms, the absence of pain and of peristalsis of the bowels above the site of the obstruction. When the disorder is due to a mesenteric thrombus or embolus, the symptoms are more acute in character and there is a history of feeble health and diseased arteries.

TREATMENT.

The occurrence of post-operative intestinal paresis can be usually prevented by the careful preparation of the patient for the operation when the condition for which it is to be undertaken is more or less chronic in character, by the regulation of the patient's diet, the proper use of cathartic medicines and the flushing out of the colon with saline solution. In those cases that are acute in character and where there is no time for this preparatory treatment, much can be done to lessen the danger of the occurrence of the trouble by washing out the patient's stomach directly after the performance of the operation before consciousness is recovered, and leaving in the organ four or five ounces of saturated solution of magnesium sulphate. The passing of a short rubber tube into the rectum at intervals of six hours, followed, after a little time has elapsed to allow of the escape of gas, by the injection into the bowel of a pint of hot saline solution, also tends to prevent the occurrence of the disorder under consideration, as it diminishes the danger of the accumulation of gas in the intestinal tract.

The initial symptoms of intestinal paresis having been recognized a seidlitz powder administered in the following manner will often end the difficulty and start the patient on the road to recovery: The contents of the blue paper having been dissolved in a tumbler nearly full of water, the contents of the white paper is dropped upon the surface of the solution at the time the patient is ready to drink it, a warning having first been given of the importance of retaining the liquid. The advantage gained by the administration of the powder in the above described manner is that the acid dissolves slowly, maintaining its agreeable taste till it is swallowed, and also that some of the gas being generated in the stomach exerts a counter pressure on the intestinal contents and thus helps to overcome the existing reversed peristaltic current and to start it once more away from the stomach and towards the anus.

The physician should personally superintend the administration of the remedy and remain with the patient until the bowels act, for the time is a critical one, and in a few hours the patient will either pass safely out of the threatened danger or be beyond hope of recovery. If the saline is retained by the patient an hour and a half later a tumbler full of hot peptonized milk will often cause the bowles to act freely, and when this occurs all danger is usually over and the patient ceases to regurgitate the stomach contents, passes gas by the bowel, and in a few hours is ready to take eight ounces of peptonized milk every three hours. Should the patient reject the saline, the writer has found it advantageous to administer a second powder within fifteen minutes, or while the patient is somewhat exhausted by the act of rejecting the first, the importance of retaining the solution being explained again to the patient, who often must be ordered in rather an imperative manner to endeavor to retain it. The second effort is usually successful, provided the condition has been promptly recognized and treatment instituted. When more time has elapsed and the tympanitic distention is greater, the patient being unable to retain any liquid in the stomach, the writer has still been able to rescue patients from their perilous condition by passing a tube into the stomach, emptying it of its contents and, after allowing as much gas to escape as would, to wash out the viscus with normal salt solution, and to place in it before withdrawing the tube four or five ounces of saturated solution of magnesium sulphate. While the treatment herein described is being carried out, strychnia in 1/30 gr. doses may advantageously be administered hypodermatically from time to time, provided it has not been previously employed in too large doses. Hypodermatic injection of atropin in 1/60 to 1/20 gr. doses have also been found useful, and C. von Noorden has used physostigmin in doses of $\frac{1}{2}$ to $\frac{3}{4}$ of a milligram with good results in overcoming the tympanities in the same condition.

Since the writer has learned to correctly interpret the meaning of the early symptoms accompanying post-operative intestinal paresis, and to appreciate their importance, there has been little difficulty in arresting the progress of the disorder by means of the treatment just outlined and of lowering a mortality rate following the performance of intra-abdominal operations in chronic cases from 10 per cent. to less than 1 per cent.

PROPHYLAXIS.

The important points for the physician to bear in mind who is called on to care for a patient who has undergone an intra-abdominal operation, if he would carry his patient safely through the convalescent period, is to abstain from using morphia, and, if the patient is restless and a narcotic drug seems necessary, to use atropia; to remember to watch the patient carefully during the first twenty-four hours, and that when she regurgitates liquid or is nauseated or even disinclined to take nourishment eighteen hours after operation, is slightly tympanitic and has passed no gas or fecal matter from the bowel, he must at once institute active measures for the sufferer's relief, and that if his diagnosis is correct his efforts will be promptly crowned with success, and in a few hours the patient will be out of all danger of an untimely end.

DISCUSSION.

Dr. Henry O. Marcy, Boston—I rise to emphasize this paper with my distinct approval. I have practiced its teachings satisfactorily for many years, and am glad the Doctor has brought this subject up for our consideration.

Dr. Daniel T. Nelson, Chicago—I have stood over these patients a number of times and appreciate the anxiety of the surgeon. I have practiced this treatment in a modified way, using the sulphate of magnesia in bulk instead of as described Dr. Wiggin. I have been in the habit for many years of using calomel first or along with it, in divided or full doses. I began with five or ten grains in a single dose, and if the patient vomited this I repeated it. I believe now that I get just as much effect from one grain given in five or ten doses as one grain given five times or in one dose. I follow the calomel with the saline. As to the general treatment of the patient, I only wish to emphasize what he has said. I believe strychnin is our sheet anchor, which he has advocated so well.

Dr. George H. Noble, Atlanta, Ga.—I will add a few words only in outlining my treatment. The patient is prepared as usual and the anesthesia is begun with nitrous oxid, followed by ether. With this method there is very much less nausea, as less ether is absorbed. I frequently operate with less than a hundred-gram can of ether. I also make it an invariable rule to wash out the stomach after administering an anesthetic to remove the mucus which has been saturated with the anesthetic. They are then put to bed and given saline solutions or stimulants they need by rectum and when necessary hypodermic medication. It is very rare that my cases are troubled with nausea and, if persistent vomiting occurs, I become apprehensive of additional causes. Dilated stomach, diseased kidney and bad hearts are contributing causes and each requires special attention. The stomach should be left absolutely empty and early evacuation of bowels encouraged. An enema of alum water is a valuable remedy. In persistent nausea from almost any cause, evacuation of the lower bowel often gives relief. The alum water was introduced by Dr. Hardon of Atlanta. He said he knew it produced vomiting when given per stomach, and supposed it would act equally as well through the rectum. He gives about one ounce in a quart of water. Now it is a standing rule with me to give this enema whenever there is any gas, colicky pain or persistent sick stomach. One or two injections give relief for three to six hours; then when the stomach becomes quiet it is my custom to administer the old compound cathartic pill. So many patients have vomited themselves so nearly to death with salts that I quit using them long ago. Two of these pills should be powdered and put in a capsule. In severe cases I give four and sometimes repeat them four, six to twelve hours. They retain these pills better than calomel, and get excellent results.

The fact that stomach lavage frequently relieves nausea, vomiting and spitting-up of contents of stomach, shows that many of the supposed cases of paresis are misjudged. It is *functional disturbance of the stomach, for if it were paresis* of intestines the mere removal of stomach contents would produce no effect, and nothing but evacuation of the bowels would give relief. It is likely due to infection (more or less limited) and too much handling and exposure of the intestines. On the other hand, the condition of the stomach mentioned can almost always be prevented by simple but careful preparation of the patient beforehand and avoidance of meddlesomeness afterwards.

Dr. H. D. Ingraham, Buffalo, N. Y.—I would like to ask the essayist if he has ever had any experience with paresis of the intestines due to fermentation of food and, if so, what he has done to relieve it. I have seen it occur even when every precaution was taken, both before and after operation.

Dr. Charles L. Bonifield, Cincinnati—Two or three years ago I read a paper on this subject, and I have not had occasion to change my views since then. I recommended the use of physostigmin, founding my belief in its value on its well-known use by veterinary surgeons in horse colic. I have used it in a number of cases, but am not sure whether I really got any marked results from it. As to the cause of this condition, I thoroughly believe that in the majority of cases it is sepsis, to a greater or less extent. Dr. Wiggin has tried to differentiate between septic peritonitis and intestinal paresis, but I think that a certain amount of sepsis is at the bottom of most of these cases. Next to sepsis, the most frequent cause is exposure of the bowel during the operation. For this reason I think it important during abdominal operations that the intestines be well protected by warm sponges.

As to the cleansing of the intestinal tract immediately before operation, I think there is a decided disadvantage in using salines of any kind. They produce watery stools, but do not remove all the contents of the bowel, especially if the patient is inclined to be constipated, when there is an accumulation in the cecum. Salines also abstract water from the system and leave the patient in a much worse condition to stand the operative shock than if some other purgative is used. I have for years prescribed the compound extract of colocynth, combining it with atropin or hyoscyamus to prevent griping. I instruct the patient to drink freely of water for two or three days before operation, so as to prepare her for the loss of some of her body fluid. Aside from purgatives, strychnin is the most valuable drug we have in the after-treatment of these patients. It is a stimulant to the nervous system, the heart and the muscular coat of the intestines. I have found it advisable when purgatives have failed to act after a thorough trial and when rectal injections also failed to secure a movement of the bowels, to stop all efforts in this direction and endeavor to stimulate and sustain the patient by hot liquid food by the stomach and stimulants hypodermically. I have not infrequently seen beef tea under these conditions stimulate peristalsis when purgatives have failed to do so. The stomach should be washed out before food is given.

Dr. Wiggin, in closing—I agree with Dr. Noble that the compound cathartic pill is one of the best remedies at our disposal with which to unload the intestinal tract, but I did not discuss the preparatory treatment of the patient for operation in my paper. I do not favor the excessive use of either salines or cathartics in getting the patient ready for operation: and I generally aim to have the patient under my care for at least a week before the operation, so that I can repeatedly wash out the colon with saline solution and can use cathartic pills or small repeated doses of calomel followed by a saline, and then have two or three days' interval before the operation so as to have the patient thoroughly rested and the system well charged with water.

In regard to the pathology of intestinal paresis: that the condition is not due to sepsis is conclusively shown by the fact that if the disorder is recognized in its early stages and proper treatment instituted, all the symptoms to which it gives rise disappear as soon as the patient's bowels move. My personal experience also seems to show that the cause of the trouble under discussion is due to injury of the intestinal nerve supply and not to sepsis, for the following reason, namely, many of my earlier cases of abdominal section terminated fatally from what was supposed to be at the time peritonitis; on opening the abdomen, postmortem, no evidence of sepsis or peritonitis was discovered and further, when later on in similar cases the abdomen was opened, antemortem, no evidence of sepsis or peritonitis was found. On puncturing the intestines at various points to allow the large volume of gas contained in them to escape, it failed to do so. My attention was long since gradually called to this class of cases from the opportunity which I had of watching two classes of patients upon whom laparotomies were performed. The first were acute conditions requiring immediate operation; the second was for chronic conditions which admitted of careful preparation of the patient for the operation, and the convalescence of the last-named class was so much smoother and quieter than in the first class, even though the operation was of greater severity. My attention was also attracted by these cases of intestinal paresis by the fact that at one of the hospitals to which I was attached, my assistants were changed in the regular routine of the hospital, every six weeks, and I found that when the laparotomy was performed on the patient twenty-four to thirty-six hours before this change occurred that the patient almost invariably died, while from the same class of operations at other periods of the interne service, the patient almost as surely recovered. Careful investigation of the matter revealed the fact that the patients who died at this time of change of assistants had not been carefully looked after and that when nauseated eighteen hours or so after the operation had not been given the usual treatment. Five or six years ago when I had begun to recognize the meaning of the symptoms of intestinal paresis, I had in my ward two patients suffering from the severe form of the trouble; they were both unable to retain the seidlitz powder solution although it had been repeatedly given to them, and realizing the desperate plight of the patients I felt justified in one case in pursuing the following treatment: I washed out her stomach through a tube with saline solution, a great quantity of gas escaping at the time; when the fluid came away clear and no more gas would escape, I left in the stomach four ounces of saturated solution of sulphate of magnesia. Five hours later her bowels moved and her further convalescence was uneventful. This procedure was unfortunately not followed in the case of the other patient, who was simply stimulated and made comfortable. This patient died twelve hours later. During the time that has elapsed since these patients were treated, intestinal paresis as a factor in the mortality of the patients upon whom I have performed abdominal operations has disappeared. It is not at all difficult to differentiate between the nausea following the administration of an anesthetic and this condition. In private practice in New York we induce the anesthetic state first with nitrous oxid, following this with ether, seldom using more than three or four ounces of ether for an operation lasting one hour, and seldom exceeding six ounces when the operation lasts for two hours, with an expert anesthetist. Using a closed inhaler it seldom requires a larger quantity of ether for the time mentioned, than when no gas is used. As a rule, little or no nausea follows, but here is the point: The vomiting which follows the administration of an anesthetic is preceded by distinct distress and nausea, whereas in intestinal paresis the contents of the stomach is ejected from the mouth without force and is not preceded by nausea or colicky pain. If the operation has been difficult and prolonged and the intestines are handled considerable, there will often be found eighteen or twenty hours after the operation that the patient has no desire for liquids, and that she is spitting up or regurgitating fluid which is at first white, then yellow, and which gradually becomes darker in color until it is nearly black, the diagnosis becoming graver as the color of the ejected fluid darkens. If no treatment is instituted in six or seven hours from the beginning of the trouble—or in twenty-four hours after the operation—the patient will ordinarily be in a hopeless condition and beyond the aid of treatment. My experience in the treatment of the condition under consideration has seemed to prove that the best remedy in the early stage of the disorder is the administration of a seidlitz powder, as described in my paper; the contents of the blue paper being dissolved in a tumbler nearly full of water, and the contents of the white paper being dropped on the surface of the solution just at the moment that the patient is ready to drink it. Therefore, if eighteen or twenty hours after the operation I find my patient unwilling to take liquid nourishment or water, I at once give the seidlitz powder; if this is retained, an hour or an hour and a half later I give the patient a tumbler of hot peptonized milk, following this the bowels usually act quickly, and the following convalescence of the patient is uneventful. I have had no experience with distention of the intestines coming on ten days or so after the operation.

I do not believe in over-medication, or the excessive use of cathartics. But I do believe fully in the necessity of the careful preparation of the patient for the operation whenever it is practicable, and that this preparatory treatment has much to do with the low rate of mortality—a fraction of 1 per cent., I believe—which has followed my operative work in the abdominal cavity for chronic conditions, for a number of years past.

THE INFLUENCE OF BILIARY ACIDS ON SURFACE TENSION.

A PRELIMINARY REPORT FROM THE CLINICAL LABORATORY OF THE DENVER AND GROSS COLLEGE OF MEDICINE.*

C. D. SPIVAK, M.D.
Clinical Professor of Medicine of the Denver and Gross College of Medicine.
DENVER.

Hippocrates noticed that when vomited matter comes in contact with marble it effervesces. It took more than twenty centuries to find the explanation of this phenomenon—namely, that marble, calcium carbonate, an alkali, dissolves with effervescence in stomach contents containing an acid.

We wonder how such an acute observation of a master mind could have lain dormant so long, and had to be rediscovered. In order to keep up our dignity we plead that we are not to blame for this oversight; forsooth, Hippocrates recorded his observations in Greek, and did not provide his works with a comprehensive index. What excuse, however, can we plead in the following case, not a hypothetical one? Here is a book written in the English language, used as a text-book in hundreds of medical colleges in England and the United States, studied by thousands of students during the last two decades, and this text-book records in clear and unmistakable terms, a remarkable observation, which nevertheless has escaped the attention of the professors, students and the medical profession at large, and which had to be brought to our cognition through the medium of the French language, only about a year ago! Let me relate this case of literary amblyopia:

Two papers appeared in the *Journal de Physiologie et de Pathologie General,* in 1901 (tome iii, pp. 99, 151; ibid., p. 461), by Frenkel and Cluzet, and Chauffard and Gouraud respectively, in which a new test for bile acids in urine is described. The discoverer of the test is supposed to be a man named Haycraft. The test is a simple one. It consists in sprinkling flowers of sulphur on urine, and if it contains bile the sulphur will sink to the bottom. This phenomenon attracted a great deal of attention, and the question naturally arose: Who is Haycraft? It took about one year to find out that Haycraft was a myth and that the author of the observation is Matthew Hay, professor of legal medicine in Aberdeen, and furthermore, that this observation is recorded as a private communication on page 294, in the "Text-Book on Human Physiology," by Landois and Stirling, second edition published by Blakiston's Son & Co., 1886, and in a somewhat abbreviated form in all subsequent editions. Thus it will be seen that an observation made by an Englishman, and recorded in a text-book that was before the medical profession for sixteen years, had to come back to us percolated through the French language and in the form of a stunning discovery of a man named Hayseed or Haycraft. Who knows how many more valuable observations are contained in our text-books which we know not? Verily, we have eyes and see not.

From the time I learned of this test from an abstract in the *Progres Medicale,* about a year ago, I have made numerous experiments on urine, and have applied this test to the study of bile acids in feces and stomach contents. The more I study this phenomenon the more wonderful and inexplicable it appears to me. A pinch of flowers of sulphur thrown on water or bile-free urine will float for weeks on the surface. On the addition, however, of one drop of bile to a quart of water the sulphur will at once sink to the bottom. We are all so accustomed to the wonderful play of colors in our various qualitative analyses that we no longer stop to marvel at them, but this test is so different in its nature from all other known modes of analytical procedures, and its sensitiveness is so extraordinarily great, that it almost borders on the miraculous.

Permit me to present a summary of the investigation with this test. Professor Hay found:

1. The test is based on the law of surface tension.*

---

* Read before the Thirty-second Annual Convention of the Colorado State Medical Society, at Pueblo, June 24-26, 1902.

* The tension of a liquid by virtue of which it acts as an elastic enveloping membrane, tending always to contract to the minimum area. It is due to the fact that while molecules in the interior are attracted in all directions, and are thus in equilibrium, those on the surface have no neighbors outside to balance the attraction of those within and are consequently acted on by a

2. The reaction is due to the presence of bile acids and not to any other constituent of the bile.

3. One part of glycocholic or taurcholic acid in 120,000 parts of water lowers the surface tension of the water and sulphur will sink to the bottom.

4. No other substance in the body except soap has the same action as bile acids.

Since the original papers in the French journal referred to above are not accessible to me, I am obliged to draw on the editorial in The Journal of the American Medical Association (March 23, 1901, p. 820) for information relative to their investigation.

1. Acetic acid, alcohol, ether, chloroform, essence of turpentine, benzoin and its derivatives, phenol and its derivatives and analin also cause the sulphur to precipitate.

2. *All fluids with a surface tension greater than fifty* dynes per centimeter do not allow sulphur to fall, and in all fluids with a tension less than fifty dynes the sulphur rapidly settles.

3. Lycopodium bears the same relation to fluids with a tension of thirty dynes as flowers of sulphur to fluids with a tension of fifty dynes.

In my own experiments I have noted the following:

1. The specific gravity of the fluid has no influence on the accuracy of the test.

2. The reaction of the fluid has no effect on the test.

3. In order to obtain correct results, the fluid must be clear. Cloudy or turbid urine must be filtered.

4. The urine must be free from bubbles.

5. Urine examined immediately after it is voided gives invariably the reaction for bile. This was a source of great annoyance to me until I found out that heat reduces surface tension. The urine must, therefore, be cooled off before the test is made.

6. In several cases where the reaction for bile pigment by Gmelin's test could not be obtained; the presence of bile acids could be demonstrated by the sulphur test.

7. In a case of syphilis of the liver, the urine gave the reaction for bile acids.

8. The urine of several patients in advanced stage of tuberculosis, with swelling of the lower extremities, gave the reaction for bile acids.

9. The stomach contents of a patient which I removed on two consecutive mornings, and which consisted almost entirely of bile, did not give the sulphur reaction.

10. Urine of three cases of pregnancy in their sixth, eighth and ninth months, respectively, gave the bile acid reaction.

11. After having experimented with more than one hundred and fifty different powders, I have found that boracic acid, iodoform, acetanilid, salol, calomel, salicylate of bismuth and salicylic acid possess this property as does sulphur, only in a feebler degree.

I shall not theorize as to the probable effect bile acids have on digestion by virtue of their ability to lower surface tension. I have not reached yet the point in my experimentation that will warrant the making of any positive assertion. I wish merely to call your attention to a new test for bile acids, the simplicity, accuracy and sensitiveness of which should gain for it universal application, and induce others to further investigation.

---

resultant force tending toward the interior. Surface tension is based on the law of capillarity, and those who wish to study the subject should consult the exhaustive bibliography and synoptical study, "References to Capillarity to the End of the Year 1900," by John Uri Lloyd and Sigmund Waldbott, Bulletin of the Lloyd Library, Pharmacy Series No. 1, 1902.

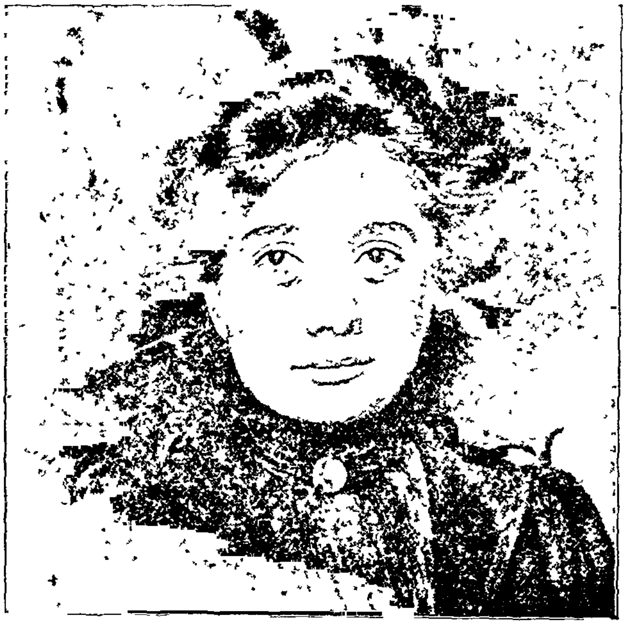
Clinical Report.

A CASE OF VICARIOUS MENSTRUATION FROM THE LOWER LIDS.

J. HERBERT CLAIBORNE, M.D.
NEW YORK CITY.

A young Jewish girl of 16 presented herself at the Vanderbilt Clinic on account of hemorrhagic spots under each eye. She was pale, flabby and badly nourished. In other respects she was well. She had menstruated for the first time at 13 years of age. Since the establishment of her menses she noticed every month, two or three days before her period, that a red spot would appear under each eye. The skin would become red, the blood would rise to the surface and finally ooze through and form a clot, which dried, resulting in a crust. This lasted during her period and disappeared gradually, so that in two or three days afterward the skin would be normal again. She also said the spots would occasionally appear two or three days after her menses and would disappear as usual.

There was a hypermetropia of a mild degree with normal vision. The interior of the eyes and the lids were normal and she did not complain of any visual disturbance. There was atrophic rhinitis with deflected septum. Dr. E. B. Coburn examined her blood and found the blood count very near to the normal, although there was a diminished quantity of hemoglobin.



The bichlorid of mercury with the compound tincture of gentian was given in this case. Her general health was much improved in consequence without the above mentioned phenomena being in any way influenced. The accompanying photograph illustrates the condition. As a rule the spots are semilunar in shape, about three-quarters of an inch below the level of the inner canthus and one-third as long as the lower lid. Dr. Geo. B. McAuliffe has referred to a case similar to this in a review on ophthalmology, published in *The Critic*, but without details. On request Dr. McAuliffe was unable to give me reference to the publication in which the case was described. I have been unable to find any other similar case on record.

39 West 36th Street.

Epidemic Infantile Paralysis.—Something not yet understood by medical science is the occasional development of an epidemic of infantile paralysis. Such an instance lately happened in Gloucester, Mass., thirty-eight cases being noted within a radius of four miles.

THEORY AND OBSERVATION IN MEDICINE.

The medical literature of this country, and for that matter of other countries also, consists of both the chaff and the wheat. Much of what is written is a mere repetition of previous work, much is pure speculation and the application of writers' theories and fads to medical subjects. A certain proportion only consists of original observations, and it is from this that our modicum of progress every year in medicine comes. This state of affairs would be discouraging, only that it is not true in medicine alone. In every science there is the complaint of the amount of writing done for the little advance gained. In every field of thought supposedly brilliant theories usurp the place of patient investigation. Any number of mare's nests are found and exploited every year. Hence despite the acknowledged value of scientific investigation, the popularity of the expression used by Amiel in the *Journal Intime:* "Science is a lucid madness occupied in tabulating its own hallucinations."

Theories fall and others rise perennially to take their places. The most striking feature in the history of medicine is the successive adoption of ever new hypotheses to accord with the scientific fad that is most prominent at the moment. Just a century ago almost to the year the great French physicist and physician Cabanis said in a review of the medical theories of his time that "every age has its peculiar taste and fashion. At different periods medicine has assumed the tone of the prevailing sciences. It has even endeavored to speak their language and to subject itself to the same rules so that it has passed successively through all the different systems that have acquired any degree of celebrity in the world."[1]

Cabanis' declaration is literally true. After Newton's discovery there was a iatro-mathematical period in medicine, especially noteworthy in England, when the reduction of therapeutics to an exact science through mathematical principles was the constant effort of the theorist. When Leibnitz ruled the world of European thought there was a period of iatro-philosophic speculation when metaphysics seemed to promise much for medicine. After the rising science of chemistry began to make itself felt, all vital reactions were explained on chemical grounds and the horizon of medicine seemed surely bounded by chemical principles. On the other hand, when physics began their notable evolution at the beginning of the present century, mechanical theories of life became predominant and therapeutics took on a physical character. It is not surprising, then, to find that the marvelous development of electricity and the successful elucidation of the chemistry of the carbon compounds should give us in our day a crop of theories as to life and health, each with a modicum of truth perhaps, but advanced as if they represented the whole field of vital activity and pointed to the only methods proper for the correction of its faults. It would not be surprising either to find that these theories so elaborately evolved would prove of as little practical value as have so many other medical echoes of current scientific thought in the history of medicine.

As a matter of fact the great mass of theorists in medicine have done little for science, but act as a brake on the wheels of progress. A distinguished medical professor of Bologna, when he heard that Harvey advanced as a proof of the circulation of the blood the fact that one could hear the heart beat, is said to have said: "Harvey may hear the heart beat in London, but we do not in Bologna." Engaged in his theoretic speculations he never even took the trouble to listen. When Auenbrugger made his demonstration of the value of percussion he practically dedicated his little book on the subject, the first important contribution to the modern science of diagnosis, to his master, Van Swieten, the head of the medical clinic in Vienna. Van Swieten wrote ten volumes of commentaries on medical subjects, two of them mainly concerned with thoracic disease, without even deigning to mention the great work of his pupil. Laennec fared some better, but received not nearly the honor that went to his contemporary Broussais the theorist, whose work, though not without its merits in a certain way, probably did more harm than good. Even in our own time Koch received all the honor at the Tenth International Medical Congress in Berlin, in 1891, while Ramon y Cajal, who brought with him to the congress his original demonstrations in brain anatomy that have since made him so famous, attracted no attention outside a narrow circle of nerve specialists.

It would be a priceless boon to medicine if the lesson could be learned that not brilliant speculation nor theories, however suggestive they may seem, are so much wanted as patient, painstaking observation. There are any number of subjects in which discoveries lie almost invitingly ready to be made. Within a few years a hospital interne, Dr. Head, has given us one of the most important series of clinical observations made in a half century by a careful investigation of the superficial skin areas that are affected sympathetically when pathological conditions develop in internal organs. Opportunities for original work are not lacking for those who seek them. Expensive laboratory equipments are by no means necessary. A wise German physician said not long ago: "The gun does not make the marksman, nor the laboratory the investigator." What is needed is patience and good will with the perseverance to follow up a subject until legitimate, practical conclusions are reached.

---

[1] Sketch of the Revolutions of Medical Science and Views Relating to Its Reform, by J. G. Cabanis, Member of the National Institute of France. London, Murray, 1806.

THE PATHOGENESIS OF CHOREA.

Although the bacteriologic proof is wanting, there is clinical evidence in favor of the infectious character of chorea. The mode of invasion of the disease, its seasonal prevalence, its self-limitation, its liability to recurrence, its occasional fatal termination, the endocardial and articular complications or associations, the postmortem findings in some cases, all point in this direction. It is true that in a number of cases lesions, sometimes macroscopic, at other times microscopic, have been found in brain and cord, but their exact relation to the clinical manifestations has not been entirely clear, while the results of such bacteriologic examinations as have been made are lacking in uniformity. Thus, certain bodies thought to be characteristic have been described as present in the central nervous system. Again, emboli have been supposed to result from the endocarditis and give rise to softening in the brain and spinal cord. Further, changes have been found especially in the ganglion cells of the cerebral cortex and considered as responsible for the symptoms.

To the inconsiderable number of fatal cases of chorea in which careful postmortem study has been made, Dr. M. Reichardt[1] adds two more. One of these occurred in a maid servant, 17 years old, who in the third week of an attack of articular rheumatism exhibited choreic movements and mental depression. The heart was enlarged to the right and a faint, soft systolic murmur was audible. Mental confusion developed suddenly, with restlessness, hallucinations and fear. The temperature rose and a state of fear set in, followed by complete loss of consciousness and death. The second case occurred in a girl, 15 years old, who had had a previous attack of chorea but a few months before. The movements were violent, the temperature was elevated and pulse and respiration were accelerated. The heart was enlarged and a loud, blowing systolic murmur was audible at the apex. The patient grew progressively worse and death took place suddenly and unexpectedly on the sixth day of the disease.

In both cases there were found on histologic study inflammation, hemorrhage and degeneration of nerve fibers in the central nervous system. The inflammatory process had involved the larger portion of the brain in varying degree, though not exceeding certain moderate limits, so that with a single exception macroscopic foci were not visible. In the one case the region of the central gray matter of the aqueduct of Sylvius and the left optic thalamus was the seat of marked disease and contained hemorrhagic inflammatory foci; and in the other the subcortical white layer was involved, with entire freedom of the basal ganglia. The ganglion cells everywhere were least affected and exhibited no definite change. The numerous hemorrhages, in part visible macroscopically, apparently distributed indiscriminately, were present throughout the brain, but accumulated especially in the situations presenting marked inflammation and also in the central gray matter and in the white matter beneath the ependyma of the ventricles. The fatty degeneration of the nerve fibers was in seat independent of the inflammatory process. It was wanting in the central convolutions and in large part in the internal capsules, but was present, in part in marked degree, in the optic thalamus, the posterior segment of the internal capsule and the transverse fibers of the knee of the capsule, as well as in the lateral white matter of the pulvinar. In the spinal cord the root fibers principally, as well as fibers in the anterior and lateral horns and isolated fibers in the posterior columns, were degenerated. The anterior and lateral columns were entirely free.

In the first case the heart was dilated and the myocarium hypertrophied. The mitral and aortic leaflets were the seat of numerous, small, recent, gray and grayish-red vegetations. Fluid from the cerebral ventricles proved sterile on culture, and no bacteria were found in the vegetations on the mitral valve, but staphylococcus aureus was obtained on culture from the heart's blood. In the second case the pericardium contained 40 c.c. of turbid, serous fluid with fibrinous coagula. The heart was dilated and the leaflets of the mitral valve were thickened and their margins the seat of pale, firm, nodular vegetations. Staphylococcus albus developed on culture from ventricular fluid and large numbers of cocci in masses and in chains were found in the endocarditic vegetations from the mitral valve, as well as emboli of cocci in capillaries, especially, however, the veins of the heart muscle of the left ventricle, and isolated incipient abscesses.

If any conclusions can be reached from the findings in the cases briefly recorded in the foregoing, together with such other evidence as is available, it is that chorea is an infectious disease, perhaps not dependent invariably upon the same micro-organism, but at different times due to different organisms. Neither is the seat of the lesion on which the symptoms peculiar to the disease depend clearly established, although it seems possible that this may be found in the basal ganglia and parts adjacent to them.

DIPHTHERIA BACILLI IN WELL PERSONS.

In 1900 the Massachusetts Association of Boards of Health appointed a committee to consider the question of the presence of diphtheria bacilli in well persons as ordinarily understood so far as the throat and nose are concerned. The report of this committee is just at hand.[1] Without considering certain questions connected with the morphological appearances that are considered as characteristic of the bacillus of diphtheria, suffice it to say that as regards the prevalence of the diphtheria bacillus in well persons the committee feels justified in the statement that in cities at least 1 to 2 per. cent. of well persons among the general public are the carriers of certain types of bacilli. Furthermore, that where well-persons are exposed to diphtheria, as in families, schools or institutions, the number of well persons harboring bacilli may range from 8 to 50 per cent. From animal and other experiments it seems that only a small percentage of the morphologically typical diphtheria bacilli found in well persons not recently exposed to the disease are virulent, but even the small proportion likely to transmit the disease constitutes an important factor in the actual spread of diphtheria. Inasmuch as persons with typical diphtheria bacilli in their throats are scattered among the general public to such an extent that in the larger cities there would be in all probabilities several thousand such cases, it would seem to be entirely impracticable to attempt to isolate the whole number, and this is one of the conclusions of this committee, provided that such persons have not, so far as known, been recently exposed to the disease. Wherever it happens that health officers or physicians learn of the existence of well persons harboring diphtheria bacilli it would be wise, of course, to give them full instructions in regard to the character of the secretions and to place a sense of responsibility on the infected person. In the case of well persons recently exposed to diphtheria in whom the bacilli are likely to be more virulent than in others the question is a little different. Even here isolation may be exceedingly difficult, and the committee does not see its way clear to make a definite recommendation in favor of isolation, but compromises by stating that infected persons in diphtheria families should not be placed under restrictions "except when it can be done without causing much friction or hardship, or unless the danger in any particular instance can be shown to be very considerable." The committee feels that it is advisable to keep children in infected families away from school and public places, that under similar circumstances the same would apply to teachers, nurses and others who come in close contact with children; that milkmen in whose households diphtheria is present should not be allowed to continue their business. When the disease appears in a community for some time free from it, then it would be advisable that all persons coming in contact with patients be isolated until shown free from bacilli. Much stress is laid on the value of education of the public to care for their persons and their secretions.

---

[1] Deutsches Archiv fur klinische Medicin, 72 B., 5, 6 H., p. 504.

[1] Journal of the Massachusetts Association of Boards of Health, July, 1902.

It will be seen that the committee has followed a middle course, considering on the one hand the various conflicting interests of the public and on the other those of the infected individual. We believe that the committee acts wisely in adopting this course. The profession is not yet willing to believe in Behring's dictum that isolation in diphtheria in reality is useless in preventing the disease because of the frequency of diphtheria bacilli in the well. We must know more about the virulence and the persistence of bacilli in the well before readjusting our prophylaxis according to Behring's ideas.

THE X-RAYS AND CANCER.

The Journal of Advanced Therapeutics, a publication largely devoted to the medical and surgical employment of physical agencies, electricity, x-rays, hydrotherapy, etc., editorially notices in its last issue that any adverse criticism of the therapeutic use of the x-ray is now rarely met in the medical literature. It argues for its early employment in malignant disease, without waiting for surgical results, and asks, why should not the x-rays preclude the knife? It does seem from the reports of specialists who have used these methods that there is a vast field for hopefulness in their employment and very little of any drawback to their use. Whether they will supplant surgery in cancer is another thing; at present there is no warrant for assuming that they will. But considering the well-recognized limitations of surgery in these cases we ought to welcome any agency that promises so much good as do the x-rays. That they have a powerful effect on the tissues is undeniable, and the evidence seems strong, if yet not altogether conclusive, that they have a selective action on certain morbid cell proliferations and that they check malignant growth, while their destructive action on surrounding healthy tissues is so much less that it can be safely considered as negligible when the beneficial effects are taken into account. Of course, every precaution should be taken to prevent untoward action, but it seems that exposures far short of affecting normal cells have a marked effect on cancer growth. Even if not curative the x-rays have a very decided palliative effect in many cases, reducing discharge, destroying offensive odor, relieving pain and generally rendering what remains of life more comfortable both to the patients and to those who have the care of them. If this alone was effected the x-ray would be an inestimable boon, but it seems that—with all due conservation—we can hope for still more. The well-known delayed effects of the x-ray may also come into play, and even if immediate results seem to be lacking there may sometimes be still a chance for later beneficial effects of the treatment. At least, this is strongly suggested by the experience of Dr. W. A. Pusey, in a case reported in The Journal, August 30.

It would be unreasonable to expect that every case of cancer will yield to the rays, yet we are justified in holding that, even with our present limited experience, the outlook for malignant disease is somewhat better since the introduction of this treatment. It does not appear that, when properly used, it is incompatible with other methods, and it may be that its greatest future usefulness will be as an adjunct to surgical measures. That its application requires caution and skill goes without saying, and the possibilities of harm from careless use must not be forgotten. There is much also to be yet learned as to the best methods and technic and its application to other than external growths or those accessible from the outside through the natural passages of the body may yet be somewhat questionable. There still remains the fact that this agency promises to be far more than a mere accessory to diagnosis, and that it may develop into a most important therapeutic resource for a class of disorders that have heretofore been considered as among the most hopeless with which suffering humanity can be afflicted.

AMERICA IN THE HISTORY OF MEDICINE.

Though it seems difficult in the light of the development of medicine as an experimental science to point out any definite practical value derived from the study of the history of medicine, still there is something more to it than the promotion of a mere leisurely culture. Osler, who is somewhat of an enthusiast on the subject, although he does not believe in adding any course on medical history to our present overcrowded curricula, finds it practicable to constantly introduce the historic standpoint in classroom and clinic.[1] A plea for such study is made by a contemporary[2] on the ground that a very desirable national stimulus is aroused by recounting national achievements. The many excellent papers emanating from the Johns Hopkins Historical Club have been well calculated to do just this for American readers. One finds his patriotism considerably stirred, for instance, by Tinker's paper[3] on American surgery, wherein we find enumerated the following twenty-three remarkably valuable surgical procedures originated by Americans: Introduction of general anesthesia: ligation of innominate common carotid, common iliac, subclavian, scapular side of scaleni; introduction of animal ligatures; treatment of aneurism by compression; nephrectomy; cholecystotomy; ovariotomy; introduction of nearly all methods of intestinal anastomosis now in use; introduction of proper treatment of appendicitis; excision of parotid; excision of superior and inferior maxillæ, clavicle, interscapulo-thoracic amputation; operation for osteomyelitis; drainage of brain abscess; manipulation in the reduction of dislocations: skin grafting; closure of defects in cleft palate; invention of the tonsillotome. This is a list well worth remembering in view of the fact that, as Tinker says, "Many American surgeons are quite familiar with the work of foreigners, but lamentably ignorant of that of their own countrymen. This is partly due to the fact that the Germans, French and English seem to take much more pride in achievements of their countrymen than we do in America, and partly because many in our country have neglected to properly record and report their cases. If we do not take pride in our own work we can not fairly expect others to do so."

THE DEATH OF PROFESSOR VIRCHOW.

The death of Virchow removes from the active rolls of science and the medical profession one of its greatest names. Many, perhaps the majority, would say without any reservation that his was the greatest name of all. We know what he was in medicine, but he was illustrious in other lines; his wonderful and versatile ability was not concentrated alone on scientific medicine; he was great as an archeologist and anthropologist and also as a statesman and philanthropist. From the revolutionary year 1848, when he first entered the political field, till his death his interest in public matters never failed, thus demonstrating that the highest scientific labors and attainments were in him perfectly compatible with active engagements in the highest duties of citizenship. What he has done for his country as a legislator is little known to most of those to whom his scientific reputation is familiar, and not all have even a comprehensive idea of the extent and range of his work as a man of science. It was a saying in Berlin that "when he died it would be found that he was not one but four men," and this is still more true for the world in general than for his own townsmen and countrymen. How he coördinated patriotism with scientific breadth of view is well known in many ways; he loyally served his country but refused to sever his scientific association with the French when requested to do so after 1870. His appreciation of the best work had no local limitations; he taught other countries than his own to recognize the merits of their own forgotten discoverers, and he could be an unsparing critic when he thought his countrymen produced unworthy work. His sharp arraignment of German literary methods two or three years back is a well-known example. No one could question his patriotism—his services so long given to his country were evidence of that—but he was above the narrowness that even the pursuit of science does not always eradicate in its workers. The whole world came to delight to do him honor during his illustrious life, and now that he has passed away full of honors and years, his memory will live after him.

Medical News.

DISTRICT OF COLUMBIA.

New Medical Building.—Work has been begun on a new medical hall for the National University. It is to be constructed of brick and stone and will cost about $50,000. The plans provide for a dispensary, three lecture and clinic halls and the smaller recitation and study rooms needed for the medical and dental departments of the university.

Surgeon General Forwood Retires.—Brigadier General William H. Forwood, surgeon general of the army, closed his active military career September 6 by operation of law on account of age. He was relieved of his duties at the head of the medical department of the army September 8 by Brigadier General Robert M. O'Reilly, who was appointed by the President several weeks ago.

Emergency Hospital Report.—The annual report of this hospital shows that 12,446 patients were received, but only 68 deaths occurred. During the year there were treated in the dispensary 7211 new cases and there were 23,345 revisits for treatment. Of these patients 739 required surgical operations and 35,204 prescriptions were issued to the patients. In the emergency department there were 5235 new cases and 4282 revisits, making practically 9517 cases treated in all. Of these cases 1921 required operation.

Typhoid in the District.—According to late reports there are now 331 cases of typhoid fever under treatment in the District of Columbia, but during the last week there were only 6 deaths from the disease. The water generally used by the people of Washington comes from the Potomac River, the intake being at a point about sixteen miles west of the city, below the mouth of the Shenandoah. Frequently after heavy rains, the water is cloudy and even muddy. The project of installing a great filtration plant has been agitated for a long time, but Congress has not provided the necessary means. Regulations governing the milk supply, more stringent than those of almost any other city, are enforced by the District government. It is believed, however, that the present epidemic of typhoid fever may be due to some common source of contamination in milk sold in certain quarters of the city, and an effort will be made to locate the source.

---

[1] British Medical Journal, July 12, 1902.

[2] Ibid, Nov. 9, 1901.

[3] Bulletin of Johns Hopkins Hospital, Aug.-Sept., 1902.

ILLINOIS.

Addition to Hospital.—A $75,000 addition is being built to St. Anthony's Hospital, Rockford, which will add 40 beds to the capacity of that institution. The new building will be ready for use about Christmas. The hospital is under the management of the Franciscan Sisters, who have seven other hospitals distributed through the states of Illinois, Iowa and Michigan.

To Determine Pollution Question.—For the purpose of determining to what extent the waters of Lake Michigan are polluted, not only by the sewers of Chicago, but by those of every other town along the lake shore from the Wisconsin to the Indiana state line, the State Board of Health is having made an exhaustive series of analyses of the lake water. Samples of the water are being collected under all possible conditions, and the work is carried on by bacteriologists of high repute. This action on the part of the state officials is undertaken largely on account of the present epidemic of typhoid in Chicago.

Chicago.

Personal.—Dr. M. L. Harris left for Wyoming, September 10, for a hunting trip. He will return early in October.——Dr. and Mrs. Julian E. Hequembourg have returned from their summer on the Massachusetts coast.

Miller Fined But Continues.—O. E. Miller, the head of the society whose hospital for inebriates was burned in June last, was fined $100, September 5, for practicing medicine without a license. The institution, nevertheless, is still in operation.

Accident to Dr. Steele.—Dr. D. A. K. Steele, president of the College of Physicians and Surgeons, is under the care of fellow members of his profession at his home, 2920 Indiana avenue. His right leg was broken while he was trying to board a car near his residence on September 5.

Prophylactic Aphorisms.—The Department of Health, in view of the typhoid situation, promulgates anew the following rules: Sterilize all drinking water; Pasteurize all milk and cream; keep flies from all food supplies; thoroughly wash in sterilized water all fruit and vegetables intended to be eaten raw and disinfect instantly all discharges of every description from those sick with typhoid.

The City's Deaths.—The 524 deaths from all causes reported during the week ended are ten fewer than the number for the week previous, but forty-one in excess of the number reported in the corresponding week of last year. The death rate per annum, per 1000, was 15. Aside from the typhoid situation the public health is satisfactory, a result largely due to the low temperature and increase of sunshine, the effects of which are chiefly seen in the mild character and low death rate of the diseases of infancy.

Water Analysis for Schools.—The Board of Education has decided to have comprehensive analyses made of the city water supply to determine whether it can safely be used by children in the public schools. Dr. John H. Long of the Northwestern Medical School will have charge of the work, and the bacteriologic examinations will be made by Professor Zeit of the Northwestern Medical School and probably by Professor Jordan of the University of Chicago. Samples of water will be taken from schoolhouses furnished with water from all the lake cribs. The work will take several weeks.

Delays Are Dangerous.—The Health Commissioner believes that as parents are compelled by law to send their children to school, it is the duty of the Board of Education to provide pure water for the children. The idea of individual children carrying bottles of sterilized or distilled water to the classroom is paltering with a serious matter. It is a demonstrated fact that typhoid fever is more prevalent in Chicago than it ever was, except in the epidemic years of 1890-'91-'92. There were 194 deaths from typhoid in August, which is the highest August record ever made by the disease in the city's history. In the first six days of September there were forty-eight typhoid deaths; in the first six days of August, twenty-two—an increase of nearly 120 per cent. The Board of Education should face these *alarming conditions* squarely and at once. Delay is dangerous. The situation demands immediate action.

The Increase of Typhoid.—Since August 2 there have been 249 deaths from typhoid fever. The disease is spreading to every quarter of the city, and the water supply from all sources is so frequently and so generally polluted that the Health Department deems it proper to refrain from characterizing any supply as "good" on any given day. There is nothing mysterious about this increase of typhoid. It is due to the polluted water supply. What is puzzling is the fact that the supply should be so polluted during unusually dry weather. Nearly eight years' *continuous observation* of the water supply and the conditions affecting it during which upward of 160,000 chemic and bacteriologic examinations have been made, by acknowledged experts, had resulted in the formulation of a belief in the laboratory that rainfall was the most potent factor in the pollution of the city water. Heretofore in dry weather the water was uniformly "good"; heretofore a rainfall of three-quarters of an inch in twenty-four hours—a quantity sufficient to flush out the sewers—was uniformly followed by water pollution. And such pollution was as *uniformly followed by an immediate increase in the intestinal-disease deaths* and later by an increase of typhoid—the former culminating, unless there was an intercurrent pollution, in about two weeks and the latter in about five weeks. For years charts have been constructed in the department showing the relation of these three factors—rainfall, water pollution, increased death rates from the impure water diseases—and they have followed each other, up to the present time, with what the *London Lancet* has styled "almost mathematical precision." But during August, 1902, and thus far in the present month there has been no sewer-flushing rainfall, the greatest amount in twenty-four hours having been only 0.57 of an inch August 13, and the total for the whole month being little more than one-half the average quantity during the last fifty-three years. Yet the water has averaged worse than during any August since these observations were begun.

MARYLAND.

Baltimore.

Faculty Changes.—Dr. John G. Jay has resigned the chair of surgery and Dr. Joseph T. Smith that of materia medica and the deanship in the Woman's Medical College.

The Baxley Professorship.—In the August 23 issue of THE JOURNAL, the Baxley Professorship of Pathology at Johns Hopkins was incorrectly announced as the "Boxley Professorship."

Typhoid Fever.—There were 38 deaths from typhoid fever in August out of a total mortality of 915. This is an unusual mortality. Forty-seven new cases of typhoid fever were reported for the week ended August 30 with 15 deaths and 99 new cases for the following week, with 10 deaths.

Personal.—Health Commissioner Bosley has returned from a visit to Nova Scotia.——Dr. Reid Hunt, associate professor of pharmacology at the Johns Hopkins Medical School, sailed for Europe, August 30.——Dr. James Bordley, Jr., of Baltimore, has been appointed professor of ophthalmology and otology in the Woman's Medical College.——Dr. Howard D. Lewis has been appointed health warden in place of Dr. Campbell F. Flautt, resigned.——Dr. Charlotte Murdoch has returned from a visit to Dr. Howard A. Kelly's hunting camp in Canada.——Dr. William Osler is at Point-a-Pie, Quebec.

Isolation of Bacillus of Infantile Diarrhea.—Dr. William H. Welch, director of the Rockefeller Institute for Medical Research, announces a discovery which promises to be of illimitable value as regards the prevention and treatment of intestinal diseases of children. After years of investigation and study the bacillus of infantile diarrhea has been isolated as a result of work recently carried on at the laboratory of the Thomas Wilson Sanitarium for Children, at Mount Wilson, ten miles from Baltimore. The organism found was identical with that which causes acute dysentery in adults. The investigation was conducted at the sanitarium by Charles W. Duval, of Annapolis, Md., a senior student at the University of Pennsylvania, and Victor H. Bassett, of Aledo, Ill., a senior student of the Johns Hopkins Medical School and pathologist to the Wilson Sanitarium. The opportunities for studying summer diarrhea have been particularly favorable at the Wilson Sanitarium, where each year during the warm months from 300 to 400 children suffering with intestinal trouble are treated. Out of

50 cases the specific organism was found in 42 It was observed that the blood of the patient had the property of clumping the germ isolated, just as blood serum in typhoid acts upon the typhoid bacillus, and this was a great help in identifying the germ, for the blood of the patient affected no other organism in a similar manner The cases investigated represented all varieties of the summer diarrhea of infants, except cholera infantum, of which there were no cases at the sanitarium this summer, and in every case the organism found to be present in the secretions was identical with that which produces acute dysentery in adults

MICHIGAN.

Burglars Shoot Physician—Dr Orletus P Eaton Detroit, was shot in the right knee while resisting two burglars who held him up at midnight, August 21, in his drug store

Detroit Hospitals Benefit—By the will of the late Senator James McMillan Grace Hospital receives $60,000, and the Home for the Friendless the Woman's Hospital and Foundlings' Home, the Children's Free Hospital Association and the Little Sisters of the Poor receive each $1000

Michigan to Missouri.—Dr. Guy L Noyes, demonstrator of ophthalmology at the University of Michigan, has been appointed professor of ophthalmology at the University of Missouri, Columbia, and Dr Clarence A Wood, assistant professor of pharmacology at Ann Arbor, has received the appointment as chief of staff of the hospital connected with the University of Missouri

Personal—Dr E B McDaniel Crystal Falls, will leave for Pekin, China, early in October He goes out under the auspices of the Presbyterian Board of Missions——Dr Robert C Bourland for three years instructor in anatomy in the University of Michigan, Ann Arbor, has resigned and returned to his home in Peoria, Ill——Dr Joseph C Tufford, Owosso, returned, September 1, after three months of study and travel in Europe——Dr Joseph A Crowell, Iron Mountain, has been appointed surgeon in chief of all mines operated by the Oliver Iron Mining Company

The Most Dangerous Communicable Diseases.—Meningitis was reported present during August at 13 places, whooping cough at 39 places, diphtheria at 41 places, smallpox at 50 places, measles at 56 places, scarlet fever at 92 places, typhoid fever at 148 places, and consumption at 227 places Reports from all sources show meningitis reported at 2 places more' whooping cough at 13 places less, diphtheria at 10 places less smallpox at 63 places less, measles at 62 places less, scarlet fever at 8 places less, typhoid fever at 63 places more, and consumption at 30 places less in August than in the preceding month

Comparative Morbidity for August—For August, compared with the preceding month, diarrhea, neuralgia, cholera morbus, cholera infantum, dysentery, influenza, typhoid fever, inflammation of kidney, inflammation of bowels and remittent fever were more prevalent, and pneumonia, measles and diphtheria were less prevalent For the same month, compared with the average for August in the last ten years, scarlet fever, pleuritis and smallpox were more than usually prevalent, and cholera infantum, consumption, dysentery, intermittent fever, inflammation of bowels, remittent fever, measles and diphtheria were less than usually prevalent

MINNESOTA.

Personal.—Dr Samuel F Hance, Minneapolis, after nearly thirty years of practice in that city, has moved to Fairport, N Y

Contagious Ward Opened—The new contagious ward at the City Hospital, Minneapolis, which has just been completed, was opened to the public, August 28

Minnesota Mortality—The report of the State Board of Health for July shows a death rate of 64 per 1000, 1135 *people out of a total of 1,751,395 having died during the* month The death rate in cities of more than 2000 inhabitants was 1 01 per 1000, in other parts of the state it was 44 per 1000 for the month Tuberculosis caused 143 deaths, only 57 of which were outside the cities Pneumonia caused 46 deaths, diphtheria 3, and cancer 50

Health Officer Sustained—The trouble at Hopkins, on account of the scarlet fever epidemic, is practically settled, and Dr Catherine A Burns, *who as health commissioner of the* town ordered the quarantine, is victorious City Physician Kistler of Minneapolis found the condition at Hopkins as Dr Burns had stated, and the contention of other local physicians that the epidemic was only German measles, has been disproved The citizens are now ready to obey the regulations of the State Board of Health

Physician Exonerated.—In the case of Margaret K Martin, appellant, against Dr Walter Courtney, Duluth, for malpractice, the case having been brought from Sherman County, the Supreme Court has sustained the finding of the lower court, which was *in favor of the defendant* Mrs Martin's husband was injured in a railroad accident, and was attended by Dr Courtney He died from blood poisoning, and Mrs Martin sued the physician for malpractice The lower court found that the doctor was *not guilty* as charged, and Mrs Martin appealed, the case now being finally settled by the Supreme Court

MISSOURI.

Personal—Dr Samuel P Stafford, St Louis, has been appointed physician at the Yakima (Wash) Indian Agency——Dr Rutherford B H Gradwohl, St Louis, has been appointed assistant chief of the Pathologic Division of the Bureau of Animal Industry in the Department of Agriculture, Washington

The Kyger Resolutions—The Kyger resolutions for the *abolition of the newspaper publication of personal medical* advertisements and advertisements of a vile and indecent nature, which have already been noticed in THE JOURNAL, were unanimously adopted by the Colorado State Medical Society at its *recent meeting in* Denver

Hospital President Fined.—Leon H Jordon, president of the new John Lange negro hospital, Kansas City, was fined $350 at a special session of the police court September 3, for violating the city ordinance passed during the summer of 1901 regulating private hospitals The ordinance requires that the management of a private hospital furnish the Board of Health with the name of the hospital, its purpose, its location, and the names and addresses of its officers, owners and managers, and must be established only with the board's approval and consent The defense was that the hospital was public and not subject to the law

The Louisiana Purchase Exposition.—The director of the Department of Liberal Arts, John A Ockerson, St Louis, has issued a prospectus showing the nature of the exhibits desired Those which come within the scope of medicine and surgery are as follows·

> Appliances instruments and apparatus for work in anatomy histology and bacteriology apparatus for sterilizing instruments and appliances for dressing wounds instruments for general and special medical research instruments and apparatus for general special and local surgery appliances for dressing wounds apparatus for plastic and mechanical prothesis orthopedic apparatus apparatus for hernia medical gymnastics material, instruments and apparatus for special therapeutics instruments and apparatus used in the practice of dentistry appliances for the use of the infirm, of invalids and of lunatics artificial limbs instrument and medicine chests for army and navy use appliances for rendering aid to the wounded on the field of battle and in case of accident ambulance service etc appliances for rendering aid to persons apparently drowned or asphyxiated and instruments and appliances for veterinary surgery

St. Louis Health Department Report.—In the fiscal year ending March 31 1902, according to the report of Health Commissioner Starkloff, there were 10,601 deaths, 754 more than in the previous year, representing a mortality rate of 17 12 per 1000 The largest death rate was in June, July and August of 1901, there being 637 more in those months than in the same period of the preceding year The increase is charged to the hot weather of last year Diphtheria *mortality* dropped from 344 to 259 There were 159 more deaths from consumption last year than in the year previous The unsanitary state of the drinking water of the city has been proven by analytical examination and the large number of typhoid cases The mortuary records for last year would show 3500 or 4000 deaths from typhoid had all the cases of that class been reported According to this estimate, there would have been 34 deaths from typhoid to 100,000 inhabitants The antitoxin investigation is reviewed without comment, as is also Dr Starkloff's bill for a Missouri general hospital, which he had introduced into the legislature a year ago The building of an institution for the care of feeble minded and epileptic children is recommended Vaccination is defended as a preventive of smallpox and other diseases

NEW YORK

Cornerstone Laid.—Governor Odell laid the cornerstone of the new Dobbs Ferry Hospital, August 29 In its private rooms and wards the new hospital will have accommodation for fourteen patients

Deaths in New York State.—There were 10,938 deaths in the state in July, according to the bulletin of State Health Commissioner Lewis. The average number for the corresponding month for the past five years has been 11,581.

Albany Hospital Changes.—Dr. Gerald Griffin has resigned to enter practice. His place on the staff has been filled by the appointment of Dr. Fred S. Lettice, Sprout Brook, who was graduated from the Albany Medical College last May.

Dr. Mann Made Honorary President.—During the sojourn of Dr. Matthew D. Mann of Buffalo in Europe he will attend the International Congress of Obstetrics and Gynecology at Rome. Dr. Mann has been elected an honorary president for America at this congress.

Buffalo Personals.—Dr. Herbert U. Williams, is in Europe. ——Dr. George Y. York has returned from a two months' vacation in Europe. Dr. Max C. Breuer, who is in Breslau, is expected to return September 18.——Dr. S. S. Green has returned from a month's fishing trip in Upper Canada.

Nurses Demand Recognition.—The New York State Nurses' Association demands legislation recognizing nursing as a profession. Legislation will prevent the probationer or pupil dismissed for unfitness from donning a uniform and calling herself a trained rurse, thus imposing on the public and endangering the lives of the patients.

Personal.—Dr. Nestor Ponce de Leon has been appointed medical inspector for the port of Havana, Cuba.——Dr. Hobart Cheesman sustained a severe scalp wound and a probable fracture of the skull, September 3, in a street-car accident.——Dr. Jesse T. Duryea, Brooklyn, superintendent of the Kings County Hospital, has resigned, to take effect November 1.

Anti-Malaria Propaganda.—The New York City Department of Health is devoting special attention to malaria, which President Lederle thinks may be more prevalent than the records of the department indicate, owing partly to the failure of physicians to report cases, and partly, perhaps, to the reporting of malarial cases under other names through mistakes in diagnosis. It is the earnest desire of the Department of Health to acquire all possible information as to the occurrence and distribution of malaria in New York City, with a view to its eventual stamping out, and physicians are requested to notify the department of all cases of malarial fever coming under their observation. Information is desired regarding the location of the fever, so that as far as possible proper measures may be taken to correct the unsanitary conditions which produce it. Malaria is always transmitted by means of the bites of certain mosquitoes (anopheles), which can be located and identified with comparative ease, and their breeding places found. In the majority of instances the occurrence of a case of malarial fever in a given locality means the existence of a breeding place of the anopheles mosquito close at hand. The investigations, therefore, will be with reference to the source of infection, the breeding places of the mosquito. To facilitate the desired notification of malaria by physicians, special postal cards have been prepared, and a supply of these cards will be sent to any physician on request. In return for such helpful co-operation on the part of physicians, the Department of Health will make free microscopical examinations of the blood for malarial parasites a part of its routine work.

WASHINGTON.

Pullman Hospital.—A hospital has been opened in Pullman under the charge of Dr. W. W. Webb, for the use of the profession of Pullman, Albion and Colton.

Dr. Thomas Wins.—Dr. Charles P. Thomas, Spokane, has been given the verdict in the damage suit for $30,000 instituted against him by W. R. Scott for criminal assault.

Personal.—Dr. Charles S. Kalb has resigned as health officer of Spokane and Dr. DeWitt C. Newman has been appointed to the position.——Dr. George W. Farmer, Hillyard, has been appointed assistant superintendent of the Eastern Washington Hospital for the Insane, Medical Lake, vice Dr. W. J. Howells, made superintendent.——Dr. Homer J. C. Birney, Whatcom, is taking a course of hospital work in London, Berlin and Vienna.

WISCONSIN.

Hospital Changes Owners.—Dr. Fred N. Brett, Green Bay, has purchased the Green Bay General Hospital and has equipped and will operate it as an institution open to any physician for the care of his patients. There are to be no wards, but each patient will have a room.

Doctors and Nurses Resign.—Four employes at the Milwaukee County Hospital, including one interne, one assistant physician and two nurses, have handed in their resignations and they have been accepted. The superintendent of the institution states that the employes had been delinquent in observing the rules of the institution pertaining to the hours which should be kept and that the violation of these rules unfitted them for duty.

Personal.—Dr. H. P. Conway has completed his service as interne in St. Mary's Hospital, Minneapolis, and has located in Spring Valley.——Dr. Daniel W. Harrington, Oshkosh, will move to Milwaukee early next month. He has been appointed to the chair of biology and physiology in Milwaukee Medical College.——Drs. W. F. Beutler, superintendent of the Milwaukee, Hospital for Chronic Insane, and Moses J. White, superintendent of the Milwaukee Hospital for the Insane, Wauwatosa, have returned from an extended European trip.

GENERAL.

Dr. Herman Commended.—Col. Maus, chief health inspector of the Philippines, highly commends Dr. M. Herman, a medical inspector of the Board of Health, for his able work. He has taken the place of the late Major Meacham, who was next in authority to Col. Maus.

CANADA.

Hospital Gifts.—$3000 has been sent to the Endowment Fund of the Montreal General Hospital. The doner asks that the gift be credited to "Anonymous." Lords Strathcona and Mount Stephen of Montreal has contributed the princely gift of $80,000 yearly to London, England, hospitals.

Physical Culture for Ontario Insane.—The Hon. J. R. Stratton, Provincial Secretary for Ontario, under whose direction are the insane asylums of the province, has decided on a complete re-organization of the system of instruction at the Orillia Asylum. He will introduce a course of physical culture in order to develop both body and mind. The Orillia Asylum is for idiots only.

Appointments.—The appointment is announced of Dr. G. H. Merrill of Montreal, to become assistant surgeon at the Hotel Dieu Hospital, to succeed the late Dr. J. A. S. Brunelle. Dr. Merrill is at present assistant professor of clinics at Laval University. He was graduated from the Victoria School of Medicine in 1876. Dr. C. W. Hopkins has been appointed house surgeon at the Montreal Maternity Hospital.

Calgary's Climate Cures Consumption.—Dr. James Stewart, Montreal, professor of medicine in McGill University, has returned home after an extended tour of the Canadian Northwest Territories. He was very much impressed with the climate round Calgary and believes that that section of the Dominion along with certain parts of British Columbia offer as good opportunities as any other climate in the world for the cure of consumption. The neighborhood of Calgary would be a very fine location for a large sanitarium.

Personals.—Dr. M. A. Curry, surgeon to the Coronation Contingent, has returned to Halifax.——Dr. J. A. McKenzie, assistant medical superintendent of the Nova Scotia Hospital, will pay an extended visit to the New York hospitals.——Dr. A. Donaldson, Brockville, Ont., who accompanied the hospital corps to South Africa with the Canadian Mounted Rifles, has accepted a commission in the British Army and will not return to Canada.——Dr. F. Montizambert, Director-General of Public Health for the Dominion, is in the west for the purpose of inspecting the Williamhead Quarantine Station.

FOREIGN.

Milk for Liverpool Poor.—The city of Liverpool furnishes to the poor at a low price sterilized humanized milk.

The Czar's Physicians.—Twenty-four physicians attend the Czar of Russia. They are a physician-in-chief, ten honorary physicians and four honorary surgeons, two oculists, a chiropodist and an honorary chiropodist, two court physicians, and three specialists for the Czarina.

Memorial to Reil.—The famous German anatomist, Reil, was buried in his garden at Halle, the gift of the ruling sovereign. The garden now forms part of the zoological gardens and the National Association of Alienists has recently fenced it in and erected a memorial.

Deaths Abroad.—The sudden death is announced of the superintendent of the Paris "Assistance Publique," Dr. C. Mourier, in his forty-fifth year.——Also of Dr. A. von Remmert, surgeon general of the Russian army and body physician to the Czar.——Dr. P. Ploss, the professor of medical chemistry at Budapest, also died recently, in his fifty-eighth year.

Wiesbaden's Ozone Water Works.—Wiesbaden has completed its plant for the application of the Siemens' process of purifying water by means of the generation of ozone by electricity. The water trickles over gravel through air-tight towers, and the ozonized air is forced through it. The ozone is soon transformed into oxygen, and the water retains no trace of the purifying process.

London Birth Rate Less.—Sociologists have been disturbed by the vital statistics issued last week, showing a marked decline in the English birth rate. London shows a decrease since 1881 from 27.4 to 20.6 per 100 of married women under the age of 45. The decline is most noticeable in the fashionable quarters of the capital, while the slum areas are almost stationary. Outside of London the decline amounts to 25.8, against 30.3 in 1881.

Special Bottles for Poisons.—One of the last acts of the late superintendent of the Paris "Assistance Publique," which has charge of all the public hospitals, was to decree that poisonous substances must henceforth be kept in three-sided bottles or jars with a rough surface on two sides. By this means it will be impossible to mistake the dangerous bottles by day or night. The Lariboisière Hospital is to be equipped at once with the new bottles, and if they prove to answer the purpose the others will be supplied in turn.

Foreign Honors to American Surgeons.—Surgeon Oliver D. Morton, U. S. Navy, has been authorized to accept a present tendered him by the Emperor of Germany. Former recipients of honors were Assistant-Surgeon William J. Wilson, U. S. Army, a decoration from the Khedive of Egypt, for gallantry in battle; Surgeon-General Rufus Tryon, U. S. Navy, a medal from the government of Venezuela, and the late Medical Inspector, George Worth Wood, U. S. Navy, a decoration from the Queen of Hawaii.

Cholera in Egypt.—The total cases since the outbreak to August 25 were 3090; 2085 deaths; 294 cured. Minieh, Assiout and Ghizeh provinces are most seriously affected. Since the first few days of the appearance of the scourge at Moucha, and subsequently at Cairo, the rapid progress of the disease has been checked by the efficiency and extraordinary energy of the sanitary department, and the situation thus improved and made more hopeful. Turkey and most of the European countries have declared Egypt infected and imposed more or less severe quarantine restrictions against travelers and traffic from that country.

Arsenic Springs Poison Many.—It is reported that 20 are dead and over 400 seriously ill at Mapiami, Mexico, as the result of the breaking forth of arsenic springs in the mountains near the city. The waters of the arsenic springs have united with those of the springs which supply the city with drinking water and the distributing reservoir is said to be thoroughly impregnated with arsenic. It was some time before the source of the poison was ascertained. According to reports, by that time hundreds were ill all over the city and physicians were wired from all the surrounding mining camps and towns. The citizens are now suffering for want of water.

Cholera in Japan and China.—The epidemic of cholera is reaching alarming proportions on the other side of the Pacific. It extends from Java to Japan and almost every city on the coast and many from the interior are affected. The disease, too, is being contracted by Europeans as well as natives. In Hong Kong from the first of the outbreak to August 6 there had been 523 cases, six of the patients being Europeans, and 511 deaths, of whom four were Europeans. In Tientsin the last report placed the number of cases for the year at 1049 and 754 deaths within the city walls and 1015 cases and 593 deaths outside the city walls. In other places in China the proportion of cases and deaths is just as great. Dispatches say hundreds have died in Java and thousands in Japan.

International Congress of Gynecology.—Nearly fifty communications are on the program of this Congress which opens its doors at Rome, September 15. The first subject to be discussed is as announced, "Medical Indications for Inducing Artificial Abortion," and addresses are to be presented by Hirst of Philadelphia, Hofmeier of Würzburg, Pinard of Paris, Rein of St. Petersburg, Schauta of Vienna and Simpson of Edinburgh. The second subject is "Hysterectomy in the Treatment of Puerperal Infection," with addresses by Fehling of Strassburg, Leopold of Dresden, Treub of Amsterdam and Tuffier of Paris. "Tuberculosis of the Female Genital Organs" will be the subject of addresses by Amann of Munich, Martin of Greifswald and Veit of Leyden. The last question on the order of the day is "Surgical Treatment of Cancer of the Uterus," with addresses by Cullen of Baltimore, Freund of Berlin, Jonnesco of Bucharest, Pozzi of Paris and Wertheim of Vienna. The thirtieth professional anniversary of Professor Porro, September 11, was to have been celebrated as a special feature of the Congress with the dedication of a ward in the Sanatorium and of an orphan asylum at Salsomaggiore in his honor, and other ceremonies. The celebration will be carried out as planned, but will take the form of a memorial. Members of the Congress are invited to Salsomaggiore for these ceremonies as guests of honor, free of expense for transportation and at the hotel. The *Presse Médicale* has organized a special excursion to the Congress, leaving Paris September 8 and returning September 24.

Miscellany.

Benzine for Transient Redness of the Nose.—Bruck has noticed that the application of benzine for a few seconds will banish temporary erythema and render the skin less shiny. The application does not irritate the skin and can be used as a prophylactic measure under circumstances liable to induce erythema in the predisposed. It is applied on a gauze compress over the entire patch of hyperemia, avoiding friction.—*Sem. Méd.*, July 16.

Difference Between Intoxication with Illuminating Gas and Carbon Dioxid.—Ferchland and Vahlen describe experimental research on dogs and frogs which demonstrated that gas is incomparably more toxic than pure carbon dioxid, consequently the toxicity can not be due to the latter alone as the gas contained only 9.7 per cent. of the dioxid. They conclude their report in the *Arch. f. Exp. Path.*, xlviii, 1 and 2, with the remark that the substances in illuminating gas to which it owes its toxicity are still as much of a mystery as those to which it owes its odor.

The Reflexes from the Standpoint of Life Insurance.—J. Crocq of Brussels delivered an address on this subject at the Second International Congress of Medical Examiners, which was held at Brussels last September. It is published in full in the *Wiener Med. Wochenschrift*, 1902, Nos. 17 to 25. He asserts that the absence of knee jerk should entail rejection of the candidate, and the nervous system must be subjected to thorough examination in case this reflex is moderately weak or exaggerated. Exaggeration is usually due to an organic lesion, but sometimes occurs with a mere neurosis. Rejection should also follow marked weakness or absence of the pupil reaction. If it is sluggish the nervous system should be investigated. No examiner should neglect to seek for Babinsky's sign and the tendon clonus, and discovery of either of them forbids acceptance of the applicant, as also of the Argyll-Robertson sign and differences in the pupils of organic origin. The other reflexes are of comparatively minor importance.

Danger from Medicine Samples.—We are pleased to note that the dangers incident to the promiscuous distribution of samples of patent nostrums are coming to be generally recognized by the municipal authorities all over the United States. Recently the Municipal Assembly of St. Paul, Minn., passed an ordinance requiring all persons who desire to distribute samples of medicines to come before the council and obtain a permit and at the same time to submit a sample of the medicine to be distributed, to the health department for examination as to its character. We have frequently seen reports of serious results following the miscellaneous distribution of so-called patent medicines. These samples are frequently left on door steps and in the reach of children lacking discretion, who may and often do do serious injury to themselves through eating the samples. In view of the reputation for vigilance borne by the health commissioner of the City of St. Paul, we feel confident that this ordinance will be so administered as to be of great service in protecting the citizens of that city against danger from this source.—*N. Y. Med. Jour.*

Acclimation of the White Race in the Tropics.—Wulffert contributes an article on this subject to the last *Vierteljahrsschrift. f. off. Ges. Pflege*, xxxiv, 3. He asserts that whenever the habitual use of alcohol has shown any effect on the nerves or muscles, the individual in question will find it difficult or impossible to live with safety in the tropics. Those intending to live in a tropical clime should train for it by years of severe manual labor or athletics in the open air, by restricting their diet to that recommended by Rubner of Cameroon in his work in *Archiv f. Hygiene*, xxxviii, p. 154, and by complete abstention from intoxicating liquors. Persons from the temperate zones should not go to the tropics expecting to till the soil. Native labor can be obtained for this, and white settlers should be overseers, superintendents, merchants, officials, artisans or soldiers, but not farmers. Rubner emphasizes the importance of water, especially with meat, to compensate for the absence of water in meat, and also for the salt eaten with it. On a diet of 16.7 calories from albumin, 16.3 from fats and 66.9 from carbohydrates, 1.803 gm. of water would be required for each calorie or 4327 gm. for 2400 calories, to which should be added 74 gm. to replace the water excreted in the feces on a mixed diet. This amounts to a total of 4401 gm., nearly four and one-half quarts of water a day, part of which can be taken in form of fruit.

Nitric Acid in Treatment of Gonorrhea.—Porosz attributes the curative effect of nitrate of silver to the nitric acid rather than to the silver, and has found the former alone extremely efficient. He injects or instills in chronic cases a .5 to 2 per cent. solution of nitric acid and in the acute form injects into the anterior portion of the urethra about 1 gm. of nitric acid in 300 to 400 gm. water. Two or three weeks complete the cure. He adds particulars in his communication to the *Wiener Med. Presse*, 1902, 10.

Ogata's Method of Reviving the Asphyxiated Newborn.—The Japanese medical journal, *Sei-I-Kwai*, xx, 8, contains a detailed description in English, with illustrations, of this method of reviving asphyxiated infants. It is now in current use in Japan, where the small rooms and low ceilings forbid the use of Schultze's swinging, and it seems from the report to be proving as effective as the latter. The legs of the child are held firmly in the right hand, the forefinger between them. The trunk of the child is then bent over as it is held in a sitting position, until the shoulders nearly touch the knees as the arms droop forward. The trunk is then bent back into the dorsal decubitus with the left hand, the arms falling free and opening the lungs. The trunk is then bent upward and forward again until the shoulders again nearly touch the knees. These movements are repeated regularly 8 to 10 times a minute and usually prove sufficient to induce natural breathing. But in severe cases, after the first and second movements, and while the infant is lying horizontally, the left hand is taken away from its back and the trunk is allowed to drop backward and downward with the arms flung wide, which expands the lungs to a remarkable extent. Ogata says of his method what Schultze said of his, that no one should venture to try it on the living subject or even to criticise it until he had done it a hundred times on the cadaver. He claims that it is very effectual and is much less distressing to an onlooker than swinging. It stimulates the circulation, especially in the medulla oblongata, the seat of the center of respiration. Ogata remarks in conclusion that "the apparent death of the newborn child from disturbance in the process accessing oxygen is one of the most discomfortable accidents that can happen during parturition," and he can confidently recommend his method for such cases after seven years of thorough testing and practical experience.

Mrs. Eddy and Common Salt.—Mrs. Eddy, she of the brilliant intellect and luminous diction, recently enriched the world with the following important item of information: "To quench the glowing flames of falsehood, once in about seven years I have to repeat this: that I *use no drugs whatever*, not even coffee, tea or red pepper, though every day, and especially at dinner, I indulge in homeopathic doses of common salt." Dr. Sweringen thus comments on the above in the *Chicago Clinic*: "I can not understand why Mrs. Eddy should indulge in common salt even in homeopathic doses, since in 'Jahr's Manual of Homeopathic Medicine,' of the edition of 1838, four and a half pages are devoted to the effects of common salt. Its mental effects are described as follows: 'Melancholic sadness, with searching for many unpleasant things, much weeping and increased by consolation, sorrowfulness about futurity, anxiousness also during a thunderstorm, chiefly at night, indolence, aversion to talk, joylessness and disinclination to labor, hasty impatience and irritability, easily frightened, hate of former offenders, fretfulness and disposition to angry violence, inclination to laugh, alternation of fretfulness and hilarity, great weakness of memory and forgetfulness, thoughtlessness and mental dissipation, misusing words in speaking and writing, inability to reflect and fatigue from mental exertion, awkwardness.' These are the effects which homeopathy attributes to common salt, which, if correct, will account for some of the idiosyncrasies, eccentricities, hallucinations, delusions, illusions, and peculiarities of Mother Eddy. I should advise her not to eat any more salt, even in homeopathic doses. It will certainly ruin her mental and physical constitution. We now know the cause of her 'thoughtlessness and mental dissipation and misuse of words in speaking and writing.' It is the use at dinner of homeopathic doses of common salt. Perhaps, if she should cease the eating of common salt, she would be better able to explain satisfactorily the occult, metaphysical intricacies of Christian Science." In our opinion, not only common salt but every bit of food these latter-day lunatics take is a direct contradiction to their tenets and a refutation of their belief in the non-existence of matter. But who would expect logic and consistency from lunatics?—*Merck's Archives.*

A Canadian's "Look-in" at the American Medical Association.—Saratoga—full of sunlight, smiling men and women meeting, greeting, and tarrying for half a week of days to attend the annual convention of the great American Medical Association. The Convention Hall is well arranged for its purpose, and blessed alike, these many moons, by meetings of Sunday School Alliances, Distillers, Sons of the Morning, Sons of the Evening (the names are not copyrighted), Jew and Gentile; in fact, all sorts and conditions of men, running the social gamut, all the way up to the splendid fifteen hundred Knights of the Scalpel, who delved into the deepest scientific problems all day, and dined and danced far into the night. Saratoga, although of late years very cosmopolitan, is diplomatic in the extreme. She knows whom she is welcoming, and arrays herself fittingly to entertain her guests. The enormous United States Hotel was "Headquarters," and to join in the throng of promenaders upon its spacious verandas and lawns, whose huge trees were ablaze with lanterns and devices of colored lights, and listen to the concert, band and vocal, arranged in honor of the delegates, was indeed a pleasure. To drive through old Saratoga's streets under the avenues of trees out to the various springs, and play "follow-the-leader," until at last the funny man of the party, as we drew up at still another Spouting Geyser, relieved our sense of polite obligation (the water was offered freely) by laughingly saying, "You may drive a horse to water, but you can't make him drink"—any more! Sometimes discretion is the better part of valor. The closing evening of the Convention, the President's reception at the United States Hotel, was brilliant in the extreme, the handsome drawing rooms flower laden, the beauty of the costumes of the ladies and the kindness of the unwearied greetings of Dr. and Mrs. Wyeth and Dr. Comstock (Chairman of the Reception Committee), made all present feel glad to be there. The museum of exhibits was also very fine, and the exhibitors vied with one another in courteous attentions to the visiting physicians. At the close of the meeting, as good-bye was said, all through the corridors echoed and re-echoed, "Till we meet again in New Orleans in May, 1903." Nothing succeeds like success, and the enthusiasm of the members carried all present alike in its flowtide of good fellowship, like a leaf on a stream. Never for a moment did the Canadian guest feel himself an alien, nor even a stranger, and he has carried home a lasting and delightful memory and a big ache in his wrist as a souvenir of the heartily extended glad-hand of his "brother chips," and in his heart old Jack and young Glory float side by side.—*Can. Jour. Med. and Surg.*

Married.

Anthony L. Rettaliata, M.D., to Miss Agnes M. Ryan, both of Baltimore, August 27.

W. B. Kirkpatrick, M.D., to Miss Susie A. Brinley, both of Path Valley, Pa., August 15.

J. Talley Spence, M.D., Alma, I. T., to Miss Mary R. Brand, of Memphis, Tenn., August 30.

William F. Berner, M.D., Merrill, Iowa, to Miss Hannah Boubeck of Chicago, August 27.

Robert M. Andrews, M.D., to Miss Clara Louise Church, both of Bergen, N. Y., August 26.

Adams B. Howard, M.D., Cleveland, Ohio, to Miss Madge Armor of Wooster, Ohio, September 4.

Louis L. Gilman, M.D., Rochester, N. H., to Miss Catherine Cunningham, of New York, August 11.

Walter E. Foster, M.D., Richmond Ill., to Miss Clara Emma Marckhoff of Elgin, Ill., August 21.

Guy L. Noyes, M.D., Ann Arbor, Mich., to Miss Lucia Weigand of Traverse City, Mich., August 27.

John J. Flynn, M.D., Worcester, Mass., to Miss M. Agnes Sweeney of North Abington, Mass., August 27.

Porter Bruce Brockway, M.D., Toledo, Ohio, to Miss Eva Marjorie Plews of Lake Linden, Mich., August 26.

Deaths and Obituaries.

THE DEATH OF PROFESSOR VIRCHOW.

Rudolf Virchow is dead. With his death on September 5, near the end of his eighty-first year, there passed away one of the most influential investigators, leaders, and teachers that medicine has known. The epochal significance of his great generalization and the basal importance of much of his work will make the name of Virchow forever prominent as are only a few in the history of the development of medicine. Endowed with a remarkable intellectual endurance he was permitted to continue his many-sided activity until well past the venerable age of four score. Some months ago he suffered an accidental fracture of the hip; from the effects of this—at that age—so ominous an injury, he apparently made a satisfactory recovery, but only to meet with a second and more serious accident that eventually led to his death.

Only the merest outline can be given at this time of the busy and eventful career of this versatile genius—pathologist, anthropologist, archeologist, hygienist and reformer. Born Oct. 13, 1821, in Schievelbein in Pomerania, he studied medicine in Berlin from 1839 to 1843, where he came under the lasting influence of Johannes Müller; in the fall of 1844 he became prosector under Robert Froriep at the Charité in Berlin, and in two years more the latter's successor. The direct outcome of this early work as prosector was a fundamental change in the technic of postmortem examination—producing eventually a technic that became the world's standard—and introducing a system of reliable autopsy records. Those who were privileged to witness these early autopsies were electrified by the secrets dead bodies were made to tell. In 1847 he and Benno Reinhardt founded the *Archiv für Pathologische Anatomie und Physiologie und für klinische Medicin*, commonly known as *Virchow's Archiv*, and since Reinhardt's death in 1852 conducted by Virchow alone. *Virchow's Archiv* is now running its 169th volume and forms one of the most important serials in scientific medical literature because of the many pioneer articles embodying the results of valuable original investigations, especially in the field of pathological anatomy and histology, that have been published in it. The influence this *Archiv* has had on the growth of scientific study in medicine can not be overestimated. Many of the earlier volumes have been reprinted again and again in order to fill the demands for complete sets in public and private libraries. The earlier numbers are especially valuable, too, because they contain many articles by Virchow himself in which he develops his views in regard to the state of scientific medicine in those days. In 1848 Virchow made a medico-sociologic study of a devastating epidemic of typhus fever in Upper Silesia, and in his report he fearlessly exposed the shortcomings of governmental officials and advocated radical reforms. He next joined in the publication of a periodical called *Medicinische Reform*, devoted to politico-medical reform measures and in which among other changes there was urged the establishment of a ministerial bureau for public hygiene. His active participation in the liberal movement connected with the revolutionary efforts of 1848 led to his dismissal from public positions in Berlin, and he accepted the offer of the chair of pathological anatomy in Würzburg, the university of which was the first to establish a full chair in this branch. Here he continued his investigations, interested himself deeply in the development of a scientific atmosphere in the university and in the matter of accurate municipal statistics of local diseases. He assumed co-editorship of Canstatt's Jahresbericht which since 1867 has been published by Virchow and Hirsch. In 1856 he was recalled to Berlin as Professor of Pathological Anatomy, General Pathology and Therapy and Director of the Pathological Institute, and here he remained until the end of his life. Only last year a magnificent new building was erected for his laboratory, and in order to house adequately the great museum that he had created during his long tenure of office.

While in Würzburg some of his more important original investigations were published, notably those on the chemistry and morphology of the blood and on thrombosis and embolism. The work on thrombosis and embolism is to a large extent experimental, and it constitutes the real starting point of our definite knowledge of these fundamental processes. In 1858 appeared his "Cellular Pathology," based upon lectures given to physicians especially, and long recognized as an immortal classic that virtually created a new era in medicine. The famous phrase "omnis cellula e cellula" "sounded the death-knell of the old humoral pathology and the birth of the new cellular pathology," which led to systematic study of the changes produced by disease in the constituent elements of the organism. Only in this way could it ever have been possible for the student to penetrate close to the real secrets of natural processes, pathologic as well as physiologic, and to arrive at general laws that would permit the formulation of scientific hypotheses in medicine. By means of the principle established by Virchow "all medicine came nearer natural processes by at least three hundred times" (Virchow), and pathology became that branch of biology which studies the disorders of cells and cell complexes. It is as the founder of cellular pathology, which Virchow himself was the first to recognize as the natural development and application of the work of his predecessors, especially Morgagni and Bichat, and of discoveries and generalization by investigators in other fields, that Virchow's name will ever remain an eminent landmark in the history of medicine. Medical men the world throughout are familiar with this aspect of his achievements. It is part and parcel of their medical education and thought, and though volumes could be written concerning the various phases of cellular pathology as it now presents itself in the light of developments that have taken place since Virchow retired from active investigation—it is now nearly half a century since he fought and won the battle for the principle of cell pathology—this is not the time nor the place for any extended discussion.

From the beginning of the publication of his *Archiv* in 1847 Virchow strongly opposed rationalism and empiricism in medicine, declaring that the time had come for the application of the inductive method to medical investigation. What was needed was close observation of individual cases by clinical and anatomical methods. In the very first volume, in the famous article in which he laid down the lines along which medicine was to advance—and along which it did advance—he says: "The filling of the clinical positions in a hospital has now become a matter of supreme importance because the clinician must be not only a scientific practitioner, but also an observer and investigator"—a remark of special significance when applied to American conditions to-day and to the discussions now carried on concerning the real university medical school. Virchow's organization of the teaching and investigation of pathologic anatomy was nothing less than masterly. It resulted in the pathologic institutes, or laboratories, which we now know are indispensable for teaching and research. His official report to the government on the need and scope of such establishments with various subdepartments, like chemical laboratory, museum, etc., written in 1846, still remains worthy of study by those interested. Thus we see clearly that he was applying general scientific principles and methods to the study and investigation in medicine, and so successful were the efforts to put an end to the day of "systems" and dyscrasias that a few years later he felt encouraged to write: "The scientific method of medical research is firmly established. It is not my merit to have discovered it. Without me it would have been found and the new trail would have been followed. But I trust the battle against the existing mixture of arbitrary rationalism and gross empiricisms, fought by the *Archiv*, in which I have aided by the introduction of genetic investigation, may have contributed much in procuring new aims for pathology."

Rud. Virchow

Virchow became famous at a remarkably early age, and his fame soon passed beyond the confines of Germany. Before long students from other lands were attracted to him, and thus the waves of his influence were carried to all parts of the world. He had in full measure the enviable power of exciting an investigative spirit in his pupils. Von Recklinghausen, Klebs, Orth, Cornil, Reisz, Axel Key, Grawitz, Cohnheim, who died all too soon, beside many, many more, have reached great prominence as teachers and investigators who carried the cellular principle of the great master to new centers, where its stimulating influence soon was felt. In 1863-67 he published his great work on tumors. Though never finished it remains to this day perhaps the most valuable work for consultation in regard to the subject. His literary activity assumed large proportions and he entered many other fields of knowledge than the purely pathologic. He became an authority in anthropology, and archeology, and achieved almost as great a reputation as writer and investigator among the workers in these sciences as he did in pathology in the minds of those who think of him as a pathologist only, and remain in ignorance of the versatility, one is tempted to say universality, of his genius.

There is one aspect of Virchow's work that merits special mention because of the example he here placed before scientific men and medical men in particular. We refer to his continuous activity, during his long life, in political and medicosocial matters. Virchow was a splendid example of the scholar in politics. Reference has been made already to his liberal tendencies and the fact that they brought him into governmental disfavor. He was elected as Prussian representative in the lower house as early as in 1848, but resigned because not old enough to hold the position legally, a position to which he was elected again in 1862. Since 1861 he served continuously in the city council of Berlin. In 1880 he was chosen a member of the Reichstag, in which he continued to occupy a seat for many years, taking a most active part in the proceedings and remaining true to his liberal convictions always. He remained a politician in the highest and best sense of the word throughout his long life, and his political career alone would insure the handing down of his name to posterity. Although not a brilliant orator in the sense the word is used in America, his words—and he spoke frequently—were always received with attention by the Reichstag because of the wisdom, courage and moderation of his views. Virchow was Bismarck's most persistent and vigorous parliamentary opponent and was once challenged to a duel by the man of blood and iron, a challenge to which Virchow paid no notice. Science and good citizenship do not exclude each other, and the humanitarian side of Virchow's work is one of its most pleasing features and one worthy of emulation everywhere, not least in our own country. In his various public capacities he exercised an immense influence on legislation of various kinds, especially when it concerned matters of public health and sanitation and the relief of the oppressed and miserable. He said: "Humanism, in its true meaning, is no apotheosis of mankind—for that would be anthropomorphism—but the scientific knowledge of the manifold and various relations of the thoughtful individual man to the ever-changing world." It is this idea of humanism that led Virchow into so many politico-sociologic undertakings. And so he became great in science and citizenship.

Beginning with his study of famine and fever in Upper Silesia in 1848 and a little later in the Spessart mountains, we find that henceforth a large part of his time and literary activity is given to questions of social and hygienic nature. These investigations made clear to Virchow that he had a sociologic mission to obey. For did he not learn that an essential factor in the causation of this epidemic was the miserable social condition of the people and that the only remedy was radical social reform? This he lived to see realized in his own and other countries. He became one of the foremost authorities in Europe on matters relating to public hygiene and sanitation. His efforts led to sanitary improvements in Berlin that all in all involved millions of dollars and caused a complete change in the physiognomy of the city. He wrote on military hygiene, on school hygiene, on the German household, on the best forms of exercise, etc. The legislation in regard to infectious animal diseases, fisheries, etc., bear his hallmark. He himself spoke of this work as half-political and as a mixture of medicine and sociology, reiterating again and again the conviction that medicine and political legislation must be brought into the closest relationship if practical medicine is to exercise the influence it should upon important problems in the life of the people. The present system of hospitals and institutions of allied nature for which Berlin is noted is further permanent proof of his constructive activities. He helped to found, and lectured to, workingmen's societies.

Few, if any, scientific medical men have received so many demonstrations in compliment of their achievements and winning personality as Rudolf Virchow. His seventieth birthday was celebrated by the publication of three large volumes of original research by fifty-four of the most prominent medical investigators, most of them being former assistants. Virchow was a regular attendant upon numerous medical and other scientific societies and congresses. For a long period of years he succeeded himself as president of the Berliner medicinische Gessellschaft. At nearly every meeting of the International Medical Congress he was chosen to deliver one of the general addresses and his appearance always caused an outburst of spontaneous applause. He refused to return his French decorations and orders, pleading that science is catholic and knows no racial or geographic bounds. In Berlin, Würzburg and Nürnburg are streets bearing his name. He was honorary member of learned societies throughout the world. These demonstrations in his honor reached their culmination on Oct. 13, 1901, his 80th birthday. Not only in Berlin but in all scientific centers was this event appropriately celebrated. Virchow himself was the recipient of some 800 congratulatory telegraphic dispatches and addresses and diplomas without end, the medical profession of Austria alone sending him 80 such. Learned societies and corporations the world over vied with one another in showing him all possible honor. In this country several banquets were arranged at which Virchow's name and achievements were toasted and lauded. The honors heaped upon him by Germany itself through her government, the learned, political, communistic and other societies were phenomenal. The Emperor conferred upon him the highest order in Prussia. Especially touching and spontaneous were the evidences of friendship and gratitude brought by the common people from his place of birth and elsewhere. Even the children of his neighborhood joined in the celebration. But in his own words the pleasantest event to him of the whole celebration was a feast in a workingman's society of which he was a co-founder. His interest in the welfare of the masses seems to have been nearest his heart, and in reviewing the eventful week of celebration of his eightieth birthday he says: "Rely on the people and work for them and you shall not fail of reward, though the cessation of numerous activities, the disappearance of numerous persons, and the complete remodeling of public life, brings home the thought of our own passing away."

Virchow had great literary powers. His writings are characterized by stringency in thought, sharpness of vision, clearness and precision of form. He was gifted with a remarkable ability to work. In his later years it may have seemed to many that his numerous interests removed him from immediate touch with the results of the more modern investigations. When bacteriology came upon the scene he remained sceptic and reserved, and did not take part in the new researches. He appeared more as a man that felt his creative work to be done and that was content to rest upon his laurels. But it is to be remembered that he always bowed before complete and definite results, though his critical spirit never slept. "Gigantic work like that performed by him during the first twenty years can not continue for ever; one new era created can not be replaced by another by one man." His own experience in regard to investigative work is illustrated in his saying that "the silent unnoticed labor of a scientist requires more energy and greater effort than the activity of the politician, which is both noisier and more speedily appreciated." And in the end the work of *Virchow the investigator* probably will be regarded as his best and greatest. When everything else is forgotten the world will remember the investigative work of his early manhood.

> We live in deeds, not years; in thoughts, not breaths;
> In feelings, not in figures on a dial.
> We should count time by heart throbs. He most lives
> Who thinks most, feels the noblest, acts the best.

We have received a cablegram from Berlin announcing that a committee of American physicians attended Professor Virchow's funeral, September 9, who presented an exquisite wreath of Easter lilies and maidenhair ferns from their countrymen practicing and studying in Berlin, with an inscription testifying to the high esteem of the medical profession of the United States for the world-renowned pathologist, Rudolf Virchow.

St. George Williamson Teackle, M.D., of Baltimore, died suddenly at his summer home near that city, August 30, from angina pectoris, aged 52. He was graduated from the University of Maryland in 1870, then spent two years at the Blackwell's Island Hospital, N. Y. He settled in Baltimore in 1872, and was physician of the Baltimore General Dispensary from 1872 to 1876, visiting physician to Bayview Asylum from 1879 to 1881 and state vaccine agent of Maryland from 1882 to 1897.

Lucretius D. Ross, M.D. Castleton (Vt.) Medical College, 1857, a prominent member of the Vermont State Medical Society and some-time president of the Rutland County Medical Society, who served during the Civil war as surgeon of the Fourteenth Vermont Volunteer Infantry, died at his home in

Pulteney, Vt., August 25, after an invalidism of nine years due to paralysis, aged 75.

William Faithful Hendrickson, M.D. Johns Hopkins University, Baltimore, 1900, instructor in pathology in the University of Pennsylvania, died at the Union Protestant Infirmary, Baltimore, from meningitis, August 21, after an illness of three months, aged 26. He was taken ill in June with broncho-pneumonia, for which he sought relief in vain in the Adirondack Mountains.

John Henry Longnecker, M.D. Jefferson Medical College, Philadelphia, 1846, a veteran of the Civil war, in which he served as surgeon of the One Hundred and Twenty-ninth Pennsylvania Volunteers and assistant surgeon at the Annapolis Hospital, and a retired practitioner of New York, died at is home in Islip, Long Island, N. Y., August 19, aged 80.

Rufus W. Griswold, M.D. College of Physicians and Surgeons, New York, 1854, a prominent physician of Connecticut, member of the state medical society, and twice president of Hartford County Medical Society, died at his home in Rocky Hill, August 17, from heart disease, after an illness of nearly two months, aged 77.

Francis W. Chadbourne, M.D. Medical School of Maine, Brunswick, 1869, one of the oldest practitioners of Lowell, Mass., a member of the Massachusetts and Middlesex North medical societies and a member of the staff of the Corporation and Lowell General hospitals, died suddenly at his home, August 21, aged 59.

William McD. Struble, M.D. University of Pennsylvania, Philadelphia, 1885, president of the board of health of Trenton, N. J., died at his residence in that city, August 28, from paralysis, aged 42. He had served as president of the Trenton Medical Association and of the Mercer County Medical Society.

George A. Bodamer, M.D. University of Pennsylvania, Philadelphia, 1884, a member of the American Medical Association, for a time chief resident physician of the German Hospital, Philadelphia, but of late years in private practice, died at his home in Philadelphia, August 20, aged 43.

George G. Verbryck, M.D. Long Island College Hospital, Brooklyn, N. Y., 1884, died at his residence in Salt Lake City, from typhoid fever, August 21, after an illness of five weeks, aged 43. The Salt Lake County Medical Society met, August 23, and adopted resolutions of respect and sympathy.

Thomas A. Mason, M.D. Medical College of Indiana, Indianapolis, 1875, died from heart disease at his home in Terre Haute, Ind., August 28, aged 58. The Vigo County Medical Society, at a special meeting held August 28, passed resolutions of condolence and regrets.

James L. Morrow, M.D. Medical College of Ohio, Cincinnati, 1853, a prominent practitioner of Delphi, Ind., who served in the Civil war as assistant surgeon and surgeon of the Seventy-second Indiana Volunteer Infantry, died at his home, August 15, aged 75.

Ralph H. Fetty, M.D. Baltimore University School of Medicine, 1888, formerly assistant superintendent of the State Hospital at Weston, W. Va., and thereafter a practitioner of Camden, died suddenly at Clarksburg, W. Va., August 24, aged 49.

James Pierce, M.D. New York University, 1871, a member of the Lawrence Medical Club and of the Massachusetts Medical Society, died at his home in Methuen, Mass., where he had practiced for more than twenty-five years, August 25, aged 54.

Joseph M. McManigal, M.D. College of Physicians and Surgeons, Baltimore, 1883, for the last four years physician at the Allegheny City Home, died suddenly at his residence in Hoboken, Pa., from heart disease, August 29, aged 39.

Thomas H. Phillips, M.D. Jefferson Medical College, Philadelphia, 1864, a surgeon in the Army during the Civil war, and family physician to the late President McKinley, died suddenly at his home in Canton, Ohio, August 30, aged 67.

John D. Briggs, M.D. Detroit (Mich.) Medical College, 1871, for more than 25 years a practitioner of Williamson, N. Y., and coroner of Wayne County for three years, died at the Rochester City Hospital, August 23, aged 66.

Archibald B. Lang, M.D. New York University, 1884, for 17 years a resident of Sault Ste. Marie, Mich., and in 1893 mayor of that city, died at his home, August 24. He was a member of the American Medical Association.

W. W. Gaither, M.D. Jefferson Medical College, Philadelphia, 1860, surgeon of the Twenty-sixth North Carolina Infantry, C. S. A., died at his home in Shallotte, Brunswick County, N. C., August 18, aged about 70.

Matthias S. Wheeler, M.D. Rush Medical College, Chicago, 1868, one of the oldest physicians of Sangamon County, Ill., died at his home in Auburn, August 27, from cancer of the stomach, after a long illness, aged 63.

Robert O. Andrews, M.D. Bellevue Hospital Medical College, New York, 1886, a prominent practitioner of East Liverpool, Ohio, and a member of the American Medical Association, died at his home, August 25, aged 65.

George B. Nichols, M.D. Rush Medical College, Chicago, 1883, a prominent member of the Vermont State Medical Society, died at his home in Barre, from Bright's disease, August 25, aged 63.

Adam O. Miller, M.D. Marion-Sims College of Medicine, St. Louis, 1891, after a prolonged debauch, shot and killed his wife and then committed suicide by taking tincture of opium August 31, aged 35.

George D. Perkins, M.D. University of Michigan, Ann Arbor, 1897, a member of the laboratory staff of Parke, Davis & Co., Detroit, died at his home in that city, September 2, from kidney disease.

Richard Oliver, M.R.C.S. Eng., and L.S.A., 1861, for nearly fifteen years resident physician at the leper settlement at Molokai, Hawaii, died at his residence in Waikiki, August 12, aged 63.

Francis E. Rosenkrans, M.D. Cincinnati College of Medicine and Surgery, 1875, died at his home in Grand Rapids, Mich., August 22, from cancer, after an illness of two months, aged 61.

J. A. Mignault, M.D. Harvard University Medical School, Boston, 1844, for many years coroner of the district of Terrebonne, Quebec, died at his home in St. Benoit recently, aged 83.

Albert E. Evans, M.D. Medical College of Ohio, Cincinnati, 1883, formerly of Chicago, died at the Dayton State Hospital, from paresis, August 28, after a long illness, aged 43.

Carl Patterson, M.D. Beaumont Hospital Medical College, 1898, a young practitioner of Denison, Texas, was drowned while swimming in Red River, August 24, aged 26.

Marion Wilkerson, M.D. Medical College of Ohio, Cincinnati, 1853, for many years a practitioner of Sabina, Ohio, died at the Soldier's Home, Dayton, August 19, aged 83.

Darwin Potter, M.D. Geneva (N. Y.) Medical College, 1860, a prominent physician of Rochester, N. Y., died suddenly at Lily Dale, N. Y., from apoplexy, August 17.

John R. Little, M.D. University of South Carolina, Columbia, 1859, died at his home in Spartanburg, S. C., August 18, after a protracted illness, aged 70.

William B. Swan, M.D., secretary of the Kansas State Board of Health, Topeka, was drowned while boating near Ludington, Mich., September 1.

Mortimer V. Wilkie, M.D. Columbia University, New York, died at his home in Cuddebackville, N. Y., August 31, after a short illness, aged 45.

P. Germain Laberge, M.D. Laval University, Quebec, 1891, died at his home in Manchester, N. H., from heart disease, August 23, aged 38.

Edwin Pratt, M.D., a retired physician of Bellefontaine, Ohio, died at his home in that city from chronic lung disease, August 25, aged 75.

B. J. Sapp, M.D., a retired practitioner of Kernersville, N. C., died at his home in that place after a long illness, August 28, aged 66.

Roy H. Hawkes, M.D. College of Physicians and Surgeons, New York, 1893, died recently from pneumonia at his home in New York City.

William D. Barber, M.D. Kansas City Medical College, 1887, a practitioner of Chicago, died at East Las Vegas, N. M., August 23.

John Simison, M.D. Cincinnati Medical College, 1850, died at his home in Romney, Ind., August 19, from typhoid fever, aged 78.

James M. Sellers, M.D. Tulane University, New Orleans, 1875, died at his home in Edna, Texas, August 24, after a long illness.

Thomas Hickey, M.D. Jefferson Medical College, Philadelphia, 1894, died at Shamokin, Pa., August 6, from tuberculosis.

H. M. Talley, M.D. Vanderbilt University, Nashville, Tenn., 1857, died at Valdosta, Ga., September 1, from apoplexy.

Ebenezer H. Thurston, M.D. University of Buffalo, 1865, died at his home in Chicago, August 25, aged 64.

J. Warren Howard, M.D., died at his home in St. Paul, Ind., August 29, from heart disease, aged 63.

Thomas C. Osborn, M.D., died at his home in Cleburne, Texas, August 20, aged 85.

Queries and Minor Notes.

COINCIDENCE—ITS PROPER VALUE IN DIAGNOSIS.

ST. LOUIS, Aug. 25, 1902.

To the Editor:—I think it would serve a useful purpose if you invited contributions to your columns concerning coincidences, and to express more clearly what I mean I will cite two cases from my own practice:

A man came to me complaining of pain in the right testis of two days' duration which he attributed to the testes having been suddenly squeezed between the left thigh and a bunch of keys in his right trouser pocket in the act of crossing his legs. No pain had ever been experienced in the part before. Examination disclosed advanced tubercular epididymitis.

A boy was brought to me supposed to be suffering from nervous shock, having been knocked over some days previously by a drunken man in the street. Routine examination commencing with the throat discovered diphtheria.

Here is a factor, then, which, as far as I know, has never been touched on in the treatises on diagnosis—coincidence. There is no escape from being obliged to give it due consideration in our mental summing-up of the case unless we examine our patients from a veterinary point of view—perhaps a better way—finding out what we can by our own unaided industry. The consideration of the particular value to be attached to coincidence would lead me further than it is my intention to trespass on your valuablo space. Recitation of cases from others would not only be highly instructive but also most interesting and would furnish a moral to adorn many a clinical tale. Yours faithfully,

J. R. CLEMENS.

ETHICS IN SUCCEEDING ANOTHER PHYSICIAN.

LAWRENCE, MASS, Aug. 28, 1902.

To the Editor:—Kindly decide this question of ethics, and oblige two members of the profession in good standing and others who may meet with a parallel case: A physician has been in attendance on a patient ten days (after miscarriage) and has made morning visit and is to call during afternoon. Meanwhile the family desires to dispense with his services—he has been paid in full for services rendered—they telephone for another physician who has no knowlidge of the circumstances until he arrives at the bedside. When he is informed that a fellow practitioner is expected to call he refuses to accept the case or give an opinion and rises to depart. The patient and her husband state that they desire his services and shall not further employ the other physician. He explains his position and ends by refusing to have anything to do with the case unless in consultation with the other physician. The family refuse to have the other physician. "Then, you must notify your attending physician not to call any more," said the second physician, "before I shall be at liberty to attend this patient." The husband goes to the physician's office and leaves notice that his services are no longer required. The husband returns and states that he was unable to see the physician personally but left word at his office for him not to call. Meanwhile, the patient suffers considerable pain. The second then accepts the case, makes examination, gives opinion and outlines treatment. He in no way solicits patronage, and neither criticised nor commented on the previous conduct of the case. Has he (the second physician) broken a rule of ethics or been guilty of conduct in any way discourteous to his fellow practitioner? Very truly yours,

JOHN T. CAHILL.

ANS.—As stated there seems to be no violation whatever of the Code of Ethics. See Art. V, Sec. 4.

MALARIA WITH ANASARCA.

MOSHER, ARK., Aug. 27, 1902.

To the Editor:—Since locating in Arkansas I have encountered a peculiar condition that the text-books fail to describe. It is an anasarca associated with or dependent on acute malarial infection. It commences with a chill and is followed by fever and sweating. About the second or third day the swelling begins and involves the whole body. The fever is now slight or wanting. The thoracic and abdominal viscera are apparently normal except a slightly enlarged spleen. Urine analysis: sp. gr. 1020, acid, amber, no sugar, no albumin, no casts. Pot. ferio cyanid, heat and nitric acid tests for albumin were carefully used. Blood examination revealed many plasmodia malaria—crescents in all cases. After giving quinin for a week or nine days a speedy convalescence ensued. The patients ranged in age from four to fifty-two years and none had had malaria for years. I would be gratified for any information as to where I can find literature on the disease or of anyone with like experience. F. L. MORSE, M.D.

WOUNDS OF THE ABDOMEN.

ALBERT, W. VA., Sept. 4, 1902.

To the Editor:—Kindly answer the following questions through THE JOURNAL: 1. Given a patient with one or several stab wounds in the abdomen, what, in your opinion, is the very shortest time in which death could result from peritonitis? 2. What is the latest treatment advised for gunshot wounds of the abdomen—wounds inflicted with the ordinary weapons? A. P. BUTT.

ANS.—1. Shock and hemorrhage can not be excluded, but when they are not dominant factors, peritonitis may result in death in 24 to 30 hours. 2. For the expert: if there is presumptive evidence of involvement of abdominal viscera, immediate operation, repair of damage and washing out of the abdominal cavity. For the ordinary practitioner: if there is strong evidence of visceral involvement, immediate operation is indicated; if not, expectant treatment.

Correspondence.

Concerning Indexes of Medical Journals.

DILLON, MONT., Sept. 4, 1902.

To the Editor:—Regarding the editorial note "Concerning Indexes of Medical Journals" in THE JOURNAL of August 30: The index furnished by THE JOURNAL is indeed a valuable addition to our comfort, but even such an index can not attain perfection, from its necessarily discontinuous publication.

I would suggest my plan of using card index. It is this: Soon after receipt and reading of each periodical, its contents are indexed on cards and a check mark placed on the journal to show that it is ready to be filed away until the volume is complete. Each periodical is given a number, which accompanies the volume numbers, for example: THE JOURNAL A. M. A. is No. 1. Then an article appearing in vol 39, page 496, on "Indexes of Medical Journals" is placed on the card devoted to "Indexing" as "1, 39-496, medical journals," meaning: THE JOURNAL A. M. A., vol. 39, page 496, indexing of *medical journals.*

I subscribe to only six journals, but in six years this amounts to 72 volumes and everything considered worth preserving is indexed at one place (in two drawers of my office desk). Thus, in a very few moments I am able to find every article on a given subject in any of the 72 volumes, and without rising from my desk. The work of indexing amounts to only a few minutes each week and the short time spent on it I consider most profitably employed. M. A. WALKER, M.D.

Priority in Perineum Repair Technic.

ATLANTA, GA., Aug. 19, 1902.

To the Editor:—In THE JOURNAL of the 16th inst. is a communication from Dr. Marcy of Boston in which he calls attention to these articles of his, viz.: Transactions of the American Association of Obstetricians and Gynecologists, September 1888, "The Perineum; Its Anatomy, Physiology and Methods of Restoration After Injury"; also "The Reconstruction of the Pelvic Structures in Woman," American Association of Obstetricians and Gynecologists, 1892; also "The Reconstruction of the Pelvic Structures Incident to Lesions of Perineum," THE JOURNAL American Medical Association, October 21, 1899. He then says: "Here will be found all the essentials of Dr. Noble's interesting article on 'A New Operation for Complete Laceration of the Perineum.'"

In reply to this most extraordinary claim I will state that the chief feature of my operation is *elimination of the danger of infection from the rectum* by dissecting the lower anterior portion of the rectum free from the vagina and drawing the uninjured portion of the anterior wall of the rectum down through and external to the anus, making an unbroken septum between the rectum and vagina, virtually converting the co plete tear into an incomplete laceration. [illegible] rcy dc [illegible] attempt to do this; his operation is the by a Marcy stitch and safety pins. He distinctly describes suturing of the rectal tear and folding of the rectal mucosa closely together, thus showing that his operation in nowise approaches mine. In my operation for incomplete tears I show that approximation of the fascia layer to layer is the feature aimed at. Nowhere in his articles does he show that he attempts this, but enlarges on buried animal sutures. The absolute want of similarity between his and my operations makes his claims most extraordinary and unwarrantable.

I, as most surgeons of this day, make no claim of buried sutures, and as they have been in use so many years in this country and in Europe, it is unnecessary to mention the name of the man who first used them. Should Dr. Marcy lay claim to everything that buried animal sutures are used in he will have a self-invested interest in a large part of the world's surgery. The buried suture is the only thing common to his and my operation for incomplete tears, and in my new operation for complete laceration it does better.

If Dr. Marcy will carefully read my paper he will see his mistake. Respectfully, Geo. H. Noble.

Accomplishments of the Finsen Apparatus in Lupus.

Brooklyn, Aug. 25, 1902.

Prof. N. R. Finsen has kindly given me photographs of one of his most interesting cases, showing the condition of the patient before (Fig. 1) and after (Fig. 2) his use of the chemical rays of light, with the tube devised by him. Fig. 3 shows a Finsen tube in position, with a patient under treatment for lupus of the nose. This is a tube which I purchased when in Copenhagen, and which I am now using with a very satisfactory degree of success.

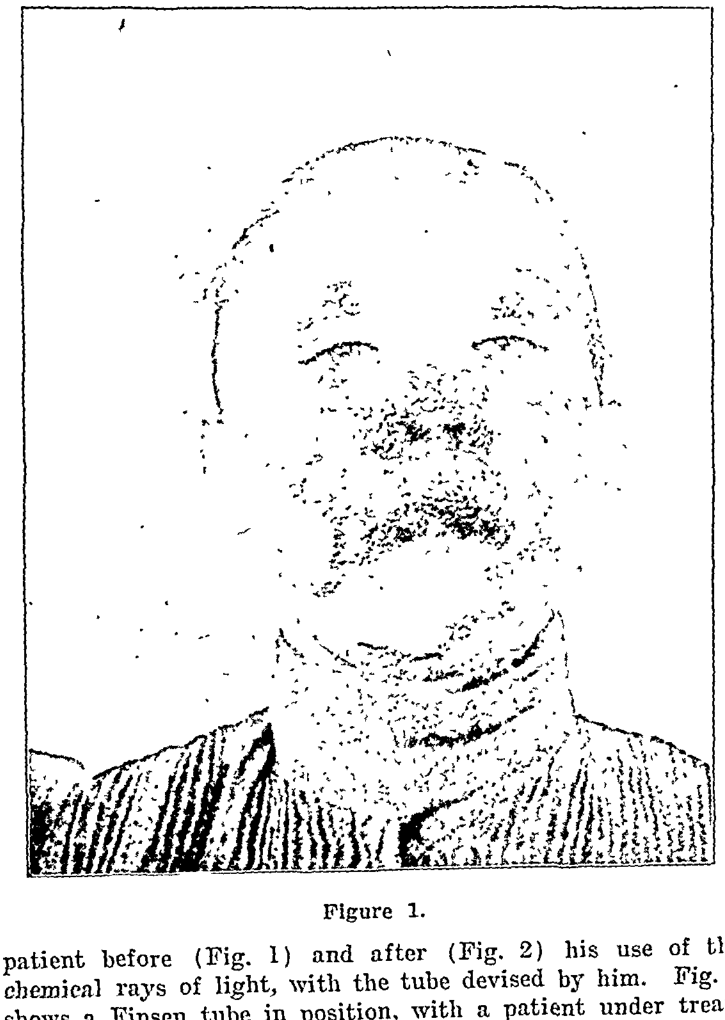

Figure 1.

The method is being used successfully in Russia, Greece and Great Britain under the patronage of the governments of these countries, also by many private physicians all over Europe. In this country there are as yet very few men working in this department. I suppose there would be more if it were not for the expense of installation and maintenance. Fig. 4 shows the new lamp devised by Dr. Bang, one of Prof. Finsen's assistants. The beauty of this is that it does not require any carbons. This is the first of this make of lamp that has reached this country, and it is certainly very ingenious in its construction. It will do excellent work but covers a smaller space than the light from the arc lamp. The amount of current consumed is so small in comparison with

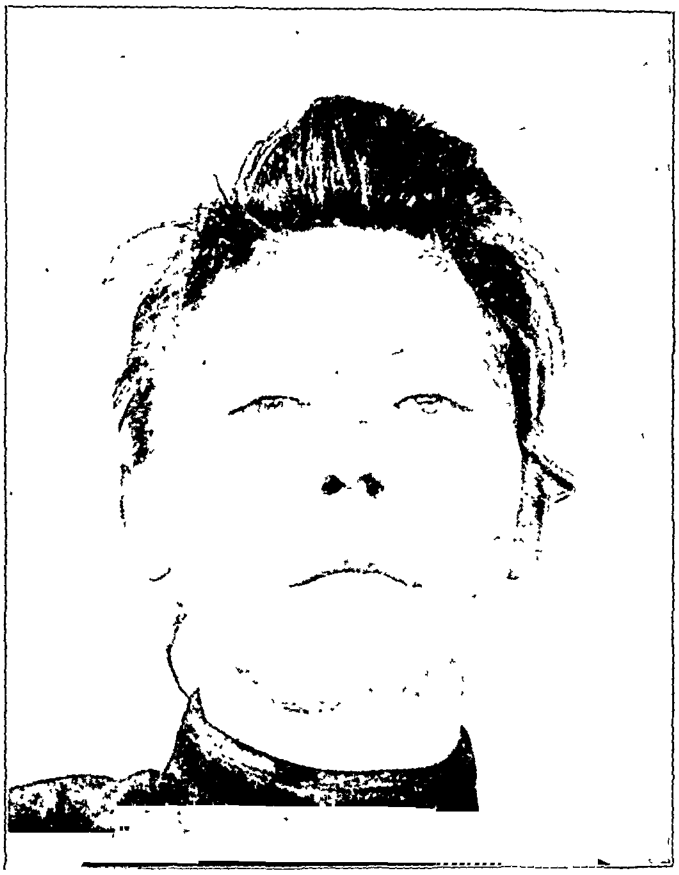

Figure 2.

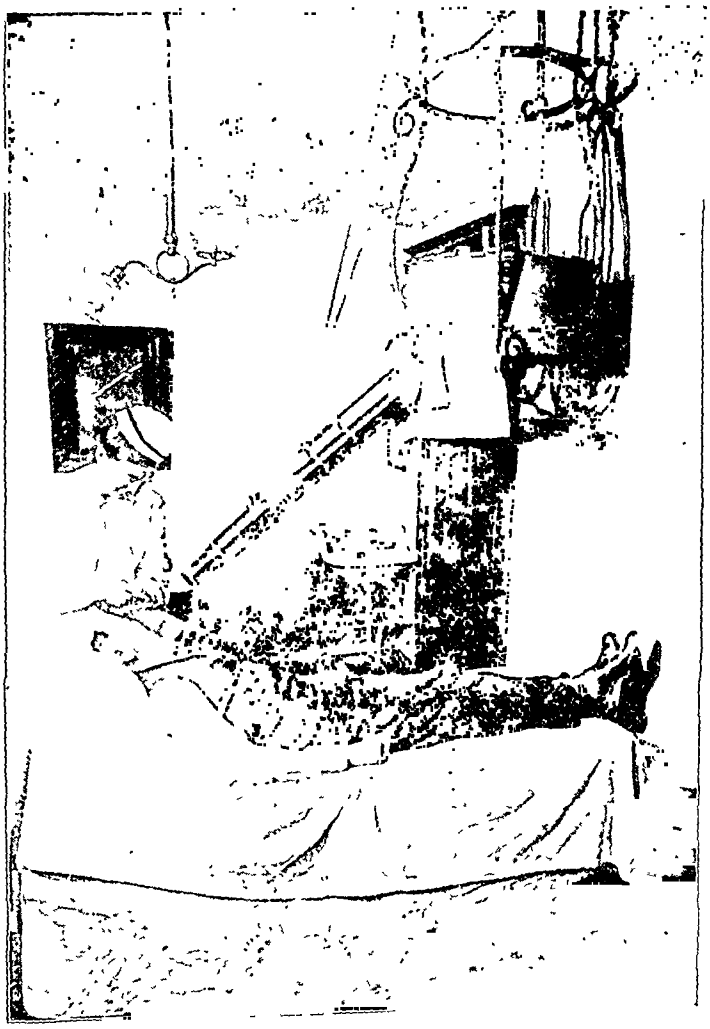

Figure 3.

the older lamp as to make it a question whether in time it may not replace the older Finsen apparatus

I trust these photographs may prove interesting, and induce more of the profession to undertake the trial of this interesting

New Instruments.

COMBINATION SURGICAL INSTRUMENT

HENRY EMERSON WETHERILL, M.D.
Surgeon Naval Reserve, Pennsylvania.
PHILADELPHIA.

THE OBJECTS OF THE INSTRUMENT.

The purpose of this instrument is to combine such surgical *instruments together that are ordinarily* used by the physician, nurse, medical student and others that may from time to time *need a few surgical tools. So* far as possible the great danger of a combination instrument, that is to say one instrument interfering with the effectiveness of another, has been overcome. The instrument is not intended to supplant ordinary instruments as in the surgeon's pocket case, but it is intended to be used where one instrument at a time is desired. It is meant particularly for emergencies, as it is an instrument that one is likely to have with him at all times and in this respect not like the pocket case which sooner or later is apt to be at home when the emergency occurs.

By the use of a small and a large form of this field instrument one is able to do most any *little* operation. After several years' experience with it, in the army, in practice, on expeditions, *here and there, it has* proved itself useful, for there are many times when you can use at least one part of the instrument. It is true *that it* would be about as difficult to pick up something and cut it off by the use of forceps and scissors, as for a dog to catch his own tail. But by borrowing another man's instrument, as might be done by a hospital corps man in the army, one could readily overcome this difficulty, providing he had but one instrument, and he would hardly need more than two for minor surgery.

The instrument consisting of but two pieces is not likely to become lost. The parts lock together and can be carried in the pocket or in a chamois case on the belt.

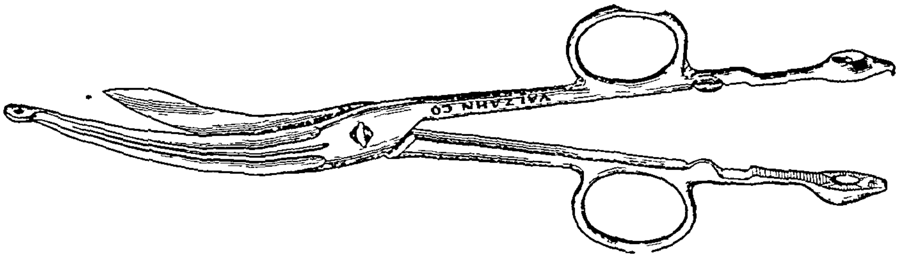
The special use for this instrument seems to be where you can not carry a *full case of instruments and* where it will do any small thing that may be required of it at that time.

THE USES OF THE INSTRUMENT.

Although the *ingenuity of the operator* will suggest many little uses to which he can from time to time put this instrument, the following are mentioned as some of the more important ones. As scissors it will give a straight or curved cut, and will work as a bandage scissors, and as scissors curved on the flat or vertical. The grooved director ends near the eyed probe end, which in a way may be used as a dry dissector. The knife blade has a curved belly and can be used as a bistoury as well as a scalpel; and when the instrument is wet with blood the loop of the scissors blade fits the third finger of the right hand and gives one a good grasp on the instrument. *The knife in this position is held securely and is well* balanced and in a good position for cutting. This blade alone held in this *manner* would *enable a* man to somewhat protect himself on the field. When the instrument is partly closed, the belly of the scalpel projects somewhat like the sharp edge of a hernia knife. The *sharp point* and *edge* are completely protected when the instrument is closed, and when open and the hemostat end of the instrument is being used, are out of the way of the wrist.

There is a long clamp between the handles of the scissors. The hemostat is handy *to pick up cut* dressings—cut with the scissors. This is readily done with one hand and the other hand does not have to be used to hold a pair of spring forceps. The loops of the instrument stay on the fingers when the hemostat portion is used as a dressing forceps. Needles of various kinds may be held by *the hemostat, and in the concavity* of the instrument a shot will rest when the needle hole running across the hemostat is used as a shot threader. A funnel-shaped opening facilitates the centering of the silkworm gut or other *material.* The needle, however, does not wabble on account of this enlargement. Between the *two rat teeth* on the upper blade a needle can be held firmly as would be desirable in teasing out fibers under the microscope.

A sharp and dull curette, one side sharp, the other blunt; rests on the top of the hemostat so as not to interfere with a ligature. On the under side *is a file* arrangement, useful in vaccination. It can readily be cleaned. There are practically no hollow corners, so the *instrument may readily be* sterilized.



There were some difficulties in producing this instrument, such as the *making* of a satisfactory lock, and a pair of hemostats that would work nicely. In offering this instrument for trial by the profession I do so [illegible] stating that it will do everything, but that I have found it useful to have with me, as it will do many of the little things one has to do every day.

3734 Walnut St.

A THIMBLE PLEXIMETER.

W. C. LANGHORST, M.D.
CHICAGO.

I have devised a pleximeter that will overcome the difficulties and complexities of the present method of percussion by making it possible not to require more than the end of the finger to be used as the hammer proper, the balance of the finger acting with the hand and wrist. In order to do this the end of the finger must be properly weighted. The amount of weight should vary with one's proficiency in the use of the present method, the less experienced the greater the weight and vice versa. The pleximeter is preferably made of metal, thimble-shaped, with a gum tip which must be of an exact size for each pleximeter; the size and thickness of this tip should vary with the weight principally.

The gum tip serves two important purposes—it protects the finger struck, and it causes the finger to which it is attached to rebound more quickly, therefore a more resonant and clear tone results. With a little practice the advantage over the unaided finger method or other methods where the force or rather resistance of the blow is not directly transmitted to the percussion finger, is readily brought out. The blow properly struck can be executed more quickly either lightly or heavily, and the tones elicited are correspondingly sharp and clear, loudness depending on the force of the blow. This method does not lessen the sense of resistance felt by the percussing finger; if there is any difference the force is intensified by the gum tip.

12 Selden Street.

Book Notices.

THE OPERATIONS OF SURGERY. By W. H. A. Jacobson, M.Ch. Oxon., F.R.C.S., Surgeon to Guy's Hospital; and F. J. Stewart, M.S. London, F.R.C.S., Assistant Surgeon Guy's Hospital, and to the Hospital for Sick Children. Fourth Edition, Revised, Enlarged and Improved. 550 Illustrations. Two Volumes: Volume I—Operations on the Upper Extremity; Operations on the Head and Neck; Operations on the Thorax. Volume II—Operations on the Abdomen; Operations on the Lower Extremity; Operations on the Vertebral Column. Cloth. Pp. 402. Price, $10.00. Philadelphia: P. Blakiston's Son & Co. 1902.

It is but a short time since the third edition of this work was reviewed, and it is now with pleasure that we announce the fourth edition. One may judge of the growth which the work has undergone since its first edition by the fact that the first edition contained only 199 illustrations, while in the fourth edition are 550.

The authors state that the work was never intended "for those of large surgical experience," but for those recently appointed on a hospital staff and for those preparing for the higher examinations. Notwithstanding the authors' modest intentions, the work is certainly one of the best that has appeared on the subject of operative surgery. It contains not only an excellent description of the technic of the various operative procedures, but an immense amount of information concerning diagnosis, indications for operation, after-treatment and results, with illustrative cases and references to the literature.

The illustrations are good and the work can be recommended to the surgeon of large experience as well as to the younger man.

A TREATISE ON DISEASES OF THE SKIN. For the Use of Advanced Students and Practitioners. By Henry W. Stelwagon, M.D., Ph.D., Clinical Professor of Dermatology, Jefferson Medical College and Woman's Medical College, Philadelphia. Handsome Octavo of 1125 Pages, with 220 Text-Illustrations, and 26 Full-page Lithographic and Half-tone Plates. Cloth. Price, $6.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

Dr. Stelwagon has here produced a very handsome and valuable treatise on the general subject of skin diseases, and one that fulfills his desire to give a practical knowledge of the symptomatology, diagnosis and treatment of the affections that are likely to be met by the general practitioner. In looking over the book we find very little of importance that is omitted and a great deal that is here given in a form perhaps not better, but certainly fully as well, as in any work of its kind. The illustrations are very numerous and helpful and the descriptions are clear. The style is readable and the work seems one that to us ought to be most favorably received by the general practitioner and referred to by the dermatologic specialist. The subject in the esthetic point of view is not an attractive one, but from a medical point of view it is one that certainly has its interest to every practitioner. Skin diseases are external and open to view and yet there are probably as much diagnostic error in practice in regard to these as there is in regard to many more recondite conditions. There is, therefore, still room for works like this by eminent specialists for the general professional edification.

A MANUAL OF SURGICAL TREATMENT. By W. Watson Cheyne, M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London, Surgeon to King's College Hospital, etc., and F. F. Burghard, M.D. and M.S. (Lond.), F.R.C.S., Teacher of Practical Surgery in King's College, London, Surgeon to King's College Hospital, etc. In Seven Imperial Octavo Volumes, with Illustrations. Volume VI, 498 Pages with 124 Illustrations. Cloth, $5.00 net. Philadelphia and New York: Lea Brothers & Co. 1902.

It was the intention of the authors to complete this work (the previous volumes of which have already been noticed in these columns) in six volumes, but they found the sixth volume would be so large, that it seemed more desirable to them to make two volumes corresponding in size to those already issued, rather than one very large one.

Section 1, of Vol. VI treats of the affections of the tongue, floor of the mouth, pharynx, neck, esophagus, stomach and intestines. Under strictures of the esophagus we find no mention of Abbe and Dunham's excellent method of treating small strictures by means of the silk thread, a most important advance in the treatment of these very troublesome cases.

Under gastroenterostomy the advisability of attaching the loop of intestine as low down or near the great curvature as possible is not made sufficiently apparent.

The subject of appendicitis is well handled, and the volume closes with a consideration of hernia.

The same excellent standard of the previous volumes is maintained.

PRINCIPLES OF SANITARY SCIENCE AND THE PUBLIC HEALTH, with Special Reference to the Causation and Prevention of Infectious Diseases. By William T. Sedgwick, Ph.D., Professor of Biology and Lecturer on Sanitary Science and the Public Health in the Massachusetts Institute of Technology, Boston. Cloth. Pp. 368. Price, $3.00. New York: The Macmillan Co. 1902.

The present volume is, the author says, the direct outgrowth of a course of lectures on sanitary science and public health given for several years by the author, professor of biology and lecturer on sanitary science at the Massachusetts Institute of Technology, to the senior students and was prepared primarily for their use. He thinks, however, that it may have a wider utility and the material herein contained may be of value to physicians, publicists and anyone who has to do with matters of public and private sanitation. It is unnecessary to say that the chapters are representative of the best knowledge of the subject. Perhaps a little more detail might have been given to one or two matters, such as the more modern methods of sewage disposal, some of which are hardly more than alluded to. On the whole, however, it gives a vast amount of well-handled information that ought to have a wide circulation among the classes above designated. Its usefulness where the matter contained is properly studied and digested can not be denied.

THE STUDY OF THE PULSE, Arterial, Venous and Hepatic and of the Movements of the Heart. By James MacKenzie, M.D. (Edin.), Burnley. Cloth. Pp. 325. Price, $4.50. New York: The Macmillan Co. 1902.

The object of this work is to give a more or less graphic statement of certain facts of the circulation as revealed by the pulse and especially to explain certain of the symptoms of the heart's action which have not been thoroughly described heretofore or erroneously interpreted. The author has attempted to reduce to order and system a vast amount of information, and while he does not claim to have been entirely successful in his attempt, the work is without doubt a contribution to our knowledge and will clear up certain facts that are more or less puzzling. Dr. Mackenzie believes in the sphygmograph and the large number of tracings which he gives throughout the book show how much he has depended on it. He says correctly if we would use graphic records to verify observations of teachings we would gain in accuracy. The book is not one that is exactly easy reading except to those who are more or less acquainted with the physical signs of the heart, but to the cardiac or thoracic specialist it ought to be of real value as a woık of reference and study.

A Manual of Practical Anatomy. By the Late Professor Alfred W. Hughes, M.B., M.C., Edin., F.R.C.S. Edin., F.R.C.S. Eng. Professor of Anatomy, King's College. Edited and Completed by Arthur Keight, M.D. Aberd., F.R.C.S. Eng., Lecturer on Anatomy London Hospital Medical College. In Three Parts. Part II. The Abdomen and Thorax. Illustrated by 4 Colored Plates and 151 Figures in the Text. Cloth. Pp. 308. Price, $300. Philadelphia: P. Blakiston's Son & Co. 1902.

The second part of this manual deals with the anatomy of the abdomen and thorax. It contains four colored plates and one hundred and fifty-one figures in the text. Most of the latter are copied from other text-books on anatomy. Throughout the book very little reference is made to fetal remains. On page 83 the appendix is said to have an average length of from four to seven inches. This is much too long, at least according to the experience of American surgeons and anatomists. The supports of the kidneys are well elucidated, and Figs. 178 and 179 show very clearly the anatomic relations and the supports themselves. Hardly enough emphasis is placed on the relation of the axis of the uterus to that of the vagina. In the thorax the importance of landmarks are pointed out, but are not well illustrated. Part II throughout is rather condensed considering the importance of the parts of the body under consideration.

The Theory and Practice of Infant Feeding, with Notes on Development. By Henry Dwight Chapin, A.M., M.D., Professor of Diseases of Children at the New York Post-Graduate Medical School and Hospital. With Numerous Illustrations. Cloth. Pp. 325. Price, $2.25. New York: Wm. Wood & Co. 1902.

Dr. Chapin's contributions to this subject in periodical medical literature are well known and this volume from his pen deserves a cordial reception. The subject is one that is so much to the front at the present time that there is little reason for denying that a work of this kind meets a want. The subject is very thoroughly and clearly treated, the book is well arranged and made up and is throughout a convenient manual on the subject. The methods of preserving, examining, Pasteurizing, and sterilizing milk are given, as well as the methods for its modification for artificial infant feeding. The different special conditions which must be met in the diet, changes for different years, etc., are all considered and in the concluding section of the work the rules for calculating the growth of infants and their measurements are given in such a way as to be readily intelligible. The book is a convenient manual for reference that every practitioner should have.

Massage and the Original Swedish Movements. Their Application to Various Diseases of the Body. Lectures Before the Training Schools for Nurses Connected with the Hospital of the University of Pennsylvania, German Hospital, Woman's Hospital, Philadelphia Lying-in Charity Hospital, the Philadelphia Polyclinic and College for Graduates in Medicine, and the Kensington Hospital for Women, of Philadelphia. By Kurre W. Ostrom, from the Royal University of Upsala, Sweden. Fifth Edition, Revised and Enlarged, with 115 Illustrations. Cloth. Pp. 181. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1902.

This is the fifth edition, the first having appeared within about twelve years. It contains considerable new material over the fourth edition and many original practical points scattered throughout the text. It is a convenient concise manual of massage and as such should find favor with the profession.

Clinical Lectures on Neurasthenia. By Thomas D. Savill, M.D., Physician to the West-End Hospital for Diseases of the Nervous System. London. Second Edition. Cloth. Pp. 171. Price, $1.50 net. New York: Wm. Wood & Co. 1902.

The first edition of this work has been already noticed in The Journal and the favorable opinion there expressed in regard to it need not be repeated. The present edition has been to some extent revised and new illustrative cases added, certain parts omitted and others changed to meet the wider experience of the author and the developments of our knowledge.

Association News.

New Members.

The following is a list of new members for the month of August:

COMING MEETINGS.

Medical Society of the State of Pennsylvania, Allentown. Sept. 16-18, 1902.

American Association of Obstetricians and Gynecologists, Washington, D. C., Sept. 16 18, 1902.

Medical Society of the Missouri Valley, Sioux City, Iowa, Sept. 18, 1902.

American Dermatological Association, Boston, Sept. 18-20, 1902.

American Academy of Railway Surgeons, Kansas City, Mo., Oct. 2-3, 1902.

Medical Association of District of Columbia, Washington, Oct. 7, 1902.

Idaho State Medical Society, Moscow, Oct. 9-10, 1902.

Vermont State Medical Society, Burlington, Oct. 9-10, 1902.

Mississippi Valley Medical Association, Kansas City, Mo., Oct. 15, 1902.

Medical Society of the State of Pennsylvania.—This society will hold its annual meeting at Allentown, September 16, 17 and 18.

Medical Society of Virginia.—This society will hold its annual meeting at Newport News, September 23, 24 and 25, under the presidency of Dr. Richard S. Martin, Stuart.

McLean County (Ill.) Medical Society.—This society has issued a very neat program for the year 1902-1903, containing a roster of its members, officers and committees, and the topics to be discussed at each meeting throughout the year.

American Academy of Railway Surgeons.—The annual session of this body will be held at the Midland Hotel, Kansas City, Mo., October 2 and 3, under the presidency of Dr. August F. Jonas, Omaha, Neb. Dr. John W. Perkins, Kansas City, is chairman of the committee of arrangements.

Reading (Pa.) Medical Association.—At the annual meeting of this association, August 25, Dr. Clarence M. Kurtz was elected president; Dr. Irvin H. Hartman, vice-president; Dr. Louis L. Thompson, secretary; Dr. Oan J. Thompson, treasurer, and Dr. S. Banks Taylor, curator.

Jessamine (Ky.) Medical Society.—The physicians of Jessamine County met at Nicholasville recently and organized this Society, with Dr. Charles Mann, Nicholasville, president; Dr. Hugh L. McLean, Wilmore, vice-president, and Dr. J. Atwood Van Arsdall, Nicholasville, secretary and treasurer.

Medical Protective League.—This league, which was organized in July, 1901, for the twofold purpose of advancing medical science, and of advancing the material interests of its members by protecting them from the "can-pay-but-won't" patients, met at Bradfordsville, Ky., September 2, and elected Dr. J. B. Evans, Riley, Ky., president, and Dr. George G. Thornton, Gravel Switch, Ky., secretary and treasurer.

Houghton County (Mich.) Medical Society.—The physicians of Houghton County met at Calumet, August 26, for organization. Dr. Albert I. Lawbaugh, Calumet, was made temporary chairman and Dr. James Hosking, Kearsarge, temporary secretary. The physicians of Keweenaw, Baraga and Ontonagon counties have been asked to join the society. The following officers were elected: President, Dr. Albert I. Lawbaugh, Calumet; vice-president, Dr. Joseph E. Scallon, Hancock; secretary, Dr. William K. West, Calumet, and treasurer, Dr. Edward T. Abrams, Dollar Bay.

Gallia County (Ohio) Medical Society.—The regular monthly meeting of this society was held in Gallipolis, September 2. Dr. Charles G. Parker, president, read his inaugural address, in which he urged that harmony and organization should be the watchwords of the society. Dr. Theodore L. Chadburne, resident pathologist of the Ohio Hospital for Epileptics, presented a specimen from a case of diaphragmatic hernia in which the patient, an epileptic, died unexpectedly after a few hours' suffering, from abdominal pain and distension following the ingestion of a large amount of unripe fruit. The stomach, transverse and portion of the ascending colon, all greatly distended, were found in the left thoracic cavity, protruding through a hernial ring in the diaphragm. Death was ascribed to the pressure of the distended intestinal viscera on the heart and lungs.

Therapeutics.

[*It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.*]

Tincture of Myrrh in Diphtheria.

Dr. Stroll, writing in the *Allgemeine Med. Centrl. Zeitung*, according to the *Indian Med. Record*, recommends very strongly the tincture of myrrh in diphtheria. The mixture he uses is composed as follows:

℞.	Tinct. myrrhæ	ʒi	4
	Glycerini	ʒii	8
	Aquæ destil. q. s. ad.	℥vi	180

M. Sig.: To be given every half hour or every hour during the day in teaspoonful doses.

The author states that infants under two years of age may take one teaspoonful at a dose and older children double that quantity. After all the membrane has disappeared the treatment should be continued for two or three days, the interval between the doses being increased to three hours. Usually the fever and lassitude disappear in twenty-four hours, so that a child may frequently be found within that time sitting up in bed playing. He states that there does not seem to be any need for local treatment; but in the case of older children and adults, a gargle containing 0.5 per cent. of resorcin may be employed every hour or oftener in the daytime, or where it is desired the tincture of myrrh, undiluted, may be painted over the tonsil every hour. When the larynx is involved the author uses the foregoing mixture in an inhaler or spray, to be used every half hour. The efficacy of myrrh is supposed to be in its ability to increase the phagocytic elements in the tonsils.

Caustic Treatment of Lupus.

According to an abstract in *Amer. Med.* the treatment of lupus by caustics is inferior to Finsen's method, cauterization, scarification, or the radical cure, but it may be employed when other methods can not be used. The following is Unna's formula in such cases:

℞.	Acidi salicylici		
	Sol. antimon. chloridi, āā	ʒss	2
	Creosoti		
	Ext. cannabis ind., āā	ʒi	4
	Lanolini	ʒii	8

M. Ft. unguentum. Sig.: After cocainizing the areas involved, apply the plaster with a spatula and cover with a zinc oxid plaster, allowing it to remain for forty-eight hours and then renew.

If the lupus is hard and unyielding, the tissues surrounding the nodules may be softened by means of alkaline caustics such as the following:

℞.	Pot. hydratis		
	Calcii (slaked)		
	Saponis nigri		
	Aq. destil., āā	℥i	30

M. Sig.: Apply locally.

The foregoing treatment is applicable only to lupus which is superficial.

Chronic Diarrhea.

Dr. M. Soupault in a recent communication to Societe de Ther., according to the *N. Y. Med. Jour.*, related the good effects of hydrochloric acid in idiopathic forms of diarrhea, where there is no important anatomic alteration in the intestine. The acid, according to the author, must be prescribed in full doses; small doses are useless. One or two grams should be given daily. The pure official hydrochloric acid containing 38 per cent. of the anhydrous acid is used. It may be ordered in the form of drops at the beginning of meals—ten, fifteen or twenty drops—in a glass of sweetened water or mixed with a little citron juice or the following lemonade may be used:

℞.	Acidi hydrochloric puri	ʒiss-ʒii	6-8
	Syrupi limonis	℥vi	180
	Aquæ	℥xxv	750

M. Sig.: Two to six tablespoonfuls at a dose.

Intratracheal Treatment of Tuberculosis.

Campbell, in *British Med. Jour.*, gives the following technic of intratracheal treatment of tuberculosis:

℞.	Thymol	ʒi	4
	Salol	ʒii	8
	Menthol	ʒi	4
	Glycerini	℥v	150

M. Sig.: To be injected into the trachea with an intratracheal syringe; or:

℞.	Medicinal izal	ʒiii	12
	Menthol	ʒii	8
	Glycerini	℥v	150

M. Sig.: To be used as an intratracheal injection.

The author injects from two drams to one and a half ounces into the trachea twice a day at a temperature of 140 degrees F. In some cases he employs the first formula for one week and then changes to the second formula. In some cases a weaker emulsion of izal should be used to begin with. The author states, with this treatment, that no irritation or coughing occurs. The duration of the treatment should depend on the individual case.

[Izal, according to Coblentz, consists of an emulsion containing about 30 per cent. of a new oil produced by a process employed in the manufacture of a special form of coke. It is claimed that its antiseptic power is greater than that of carbolic acid, while it is practically non-toxic.]

Baths in Diseases of the Skin.

In acute eczema, urticaria or psoriasis in children, the following formula is of service, to be used in the bath:

℞.	Sodii bibor.		
	Sodii bicarb., āā	℥i	30
	Pot. carb.	℥iii	90
	Pulv. amyli	℥iv	120

M. Sig.: One to three tablespoonfuls to each gallon of water, to be used in the bath.

In cases of pruritus the following:

℞.	Sodii carbonatis	℥ii	60
	Sodii biboratis	℥ii	60
	Pot. carb.	℥iii	90

M. Sig.: One such powder to be used in thirty gallons of water with one-half a pound of starch. The starch should be previously boiled with water in order to make a clear solution.

The following lotion is recommended in the treatment of acne and eczema:

℞.	Pulv. zinci carb. precip.		
	Pulv. cretæ prep., āā	ʒi	4
	Glycerini	ʒiii	12
	Acidi hydrocyani dil.	ʒss	2
	Liq. calcis	℥iii	90
	Aquæ rosæ		

M. Sig.: To be used locally.

In the erythematous and papular varieties the following combinations are recommended in *Applied Ther.*:

℞.	Zinci oxidi	ʒii-ʒiv	8-16	
	Acidi carbol.	gr. xx	1	30
	Mucilag. acaciæ	ʒii	8	
	Emul. amygdalæ	℥ii	60	
	Aquæ q. s. ad	℥viii	240	

M. Sig.: Apply locally.

An ointment similar to the following containing calamin is also recommended:

℞.	Calaminæ	ʒi	4
	Ung. zinci oxidi	ʒvii	28

M. Sig.: Apply locally to the affected parts; or the following:

℞.	Calaminæ			
	Zinci oxidi, āā	gr. xl	2	65
	Amyli	ʒi	4	
	Acidi salicylici	gr. x		65
	Petrolati q. s. ad.	℥i	30	

M. Sig.: To be used locally.

In the subacute form of eczema the following is recommended:

℞.	Zinci oxidi	ʒii	8
	Liq. plumbi subacet.	ʒvi	24
	Glycerini	ʒii	8
	Inf. picis liq., q. s. ad	℥iv	120

M. Sig.: As a local application.

Eczema of the Genitals.

Lutaud, in *Gaz. des Hôpitaux*, recommends the following as a lotion in eczema of the genitals:

℞.	Potassii chloratis	gr. xx	1	30
	Vini opii	*gtt. xlv*	3	
	Aquæ	℥viii	240	

M. Sig.: Apply locally to the affected parts.

Vulvar Pruritus.

H. Guilhot, in *Le Prog. Médical*, recommends the following:

℞.	Sodii hyposulphitis	gr. xlv	3
	Adipis lanæ hydrosi	℥i	30

M. Sig.: To be rubbed over the affected parts frequently.

Erysipelas.

The new treatment for erysipelas, according to the *Dietetic and Hygienic Gaz.*, consists simply in covering the affected area and a portion of the surrounding skin with a thick layer of white vaselin. This in its turn is covered with a mask of linen, and held in position by means of gauze bandages. The application is made twice a day. The results obtained by this method are very favorable and gratifying when compared with those following other methods, as painting with tincture of iodin, ichthyol or sublimate solution, etc. Fever, as a rule, diminished within two or three days, pain and tension in the affected parts were relieved, and recurrences were observed with no more frequency than in cases in which other methods were employed. The advantages claimed for this treatment are the absence of pain and irritation which accompanies the application of iodin or the bichlorid.

Medicolegal.

Thirty-Five Thousand Dollars for Loss of Legs.—The Court of Civil Appeals of Texas holds, in Gulf, Colorado & Santa Fe Railway Company vs. Shelton, that where a business man, 49 years of age, who had never been sick a day, was so injured as to necessitate the amputation of his right leg three inches above, and of his left leg nine inches below, the knee, an award of $35,000 damages could not be considered excessive.

Voidable Releases in Personal Injury Cases.—The Court of Appeals at St. Louis, Mo., holds, in the personal injury case of Roberts vs. the Central Lead Company, that where a party signs a release of a cause of action for personal injuries, and at the time is unable to fully understand the nature of the document because of physical and mental weakness produced by his injuries and the necessary use of drugs, a court of equity will rescind the release on timely application and the refunding of its consideration. Where a duty rests on a party to refund a sum of money as incident to the rescission of a release, it should be performed with reasonable diligence, in view of the circumstances. In Houston & Texas Central Railroad Company vs. Brown, the latter party, after his injury, executed a release to the company, relieving it from further liability. The Court of Civil Appeals of Texas finds that the execution of this release was obtained and based upon representations made by a physician who was then the agent and the representative of the company in the treatment of the party at an infirmary, to the effect that the bones of his arm had knitted and united together, and that the arm was well, and that as soon as the swelling had passed away his arm would be as good as ever; that he was on the safe side, and could safely make a settlement with the company for his injuries. This statement and representation by the physician was predicated on a statement by the party to the effect that he was willing to settle with the company, and release it from all claims for damages because of the injuries, whenever the bones of his arm had knit together and his arm was cured. The facts in evidence, the court says, warranted the conclusion that the physician made the representations and statements to the party for the purpose of inducing him to execute the release, and that the party believed the statements were true, and relied upon the same, and was thereby induced to make the settlement and sign the release, while the representations and statements so made were false, in that the bones at the time of the trial were not united, and that the arm was practically destroyed in its usefulness. And the court says that it can not agree with the contention of the company that it might escape liability on the ground that the representations and statements made by the physician were a mere expression of opinion. It was more than an opinion—it was the statement of a fact. The effect of his statement was that the party was a sound man, and that the bones of his arm had knitted together, and that it would be all right. It was true that this statement might have been predicated on his opinion as a medical expert, but the opinion was based on facts of which he possessed knowledge. The fact that the statement made by the physician was not intentionally false did not affect the right of the party to have the release set aside if he was misled by the statement, and executed the release believing the statement was true. In such a case, innocent misrepresentations may as well be the basis of relief as where such statements are intentionally false.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures and single case reports are omitted unless of exceptional general interest.

New York Medical Journal, August 30.

---

1. **Neurotic Children.**—Neurotic children are defined by Hammond as those whose nervous force is below the normal standard. The nerve elements, either from heredity or accident, or both, are poorly developed and are therefore incapable of normal resistance and never reach proper physical development. He believes by proper training these handicaps for the future can be removed and that the training should begin as soon as the neurotic element is discovered. He lays much stress on the diet, which should be mainly nitrogenous. He has no confidence in the notion that epilepsy is favored by this diet. Caution should be given as to overfeeding. Moral treatment is of great importance; the child should be required to be kept firmly in hand, and taught strict obedience and self-restraint and to control the emotions. It is advisable not to press the intellectual development; this is specially important up to seven or eight years of age. The education should be very cautiously advanced; such children need restraint more than others, with careful attention to the diet, sleep, the bodily functions, fresh air and proper clothing. With systematic, well-regulated and long-continued physical culture there should be no remains of the neurotic predisposition as the child enters manhood.

2. **The Carrying Function of the Arm.**—Hoffman points out the abnormalities of the arm affecting its passive carrying function. The forearm should diverge from the upper arm at an angle of about 170 instead of a straight line and destruction of this carrying angle may be brought about by fractures, rachitis or anything that changes the articular surface from one facing a little outward to one facing directly downward or slightly inward. He illustrates his views with pictures and describes his operation, in which he made a dissection of the soft parts to the humerus just above the inferior condyle, cutting three-fourths through the bone and reflecting it slightly outward, making a new carrying angle above the joint. He operates from the inner side to avoid involving the musculospiral nerve, and because it is better to bend the bone away from the cut and toward the position of correction, thus leaving unbroken the covering of the periosteum on the outer side. Simple section of the inner side will give a longer arm than a cuneiform operation on the outer.

11. **Meningitis.**—The value of lumbar puncture in the diagnosis of meningitis, especially tubercular meningitis, is insisted on by Hand. Only a few of the ordinary objective symptoms of meningitis may be present and many of them may be present when meningitis is not. The changes which occur in the cerebrospinal fluid as the result of meningitis are diminution or absence of sugar, the increase of albumin, and excepting in the simple serous meningitis, the presence of leucocytes, bacteria and frequently endothelial cells. The presence of sugar when other signs indicate meningitis is suggestive of tubercular disease, but its absence does not exclude tuberculosis. Complete absence of sugar is said to be the rule in other forms of meningitis except in the serous in which it is much diminished. The normal amount of albumin in the cerebrospinal fluid is said to have the maximum unit of .25 per 1000. It is usually reduced in meningitis, though it may also be reduced in the normal cases, and in tuberculous meningitis it seems to be rather higher than in other forms. According to Hand's experience a definite count of leucocytes is often difficult or impossible, but when the handling is very careful, the count is of great value. He found polynuclears in excess in all the cases in which tubercle bacilli were not discovered. The bacteria which he has found have been the tubercle bacillus, the pneumococcus, unidentified cocci, and an intracellular diplococcus, probably the meningococcus, which did not grow on blood serum or agar. In several cases the tubercle bacilli were associated with cocci so that the presence of other germs does not exclude tuberculosis. He describes his technic as follows: "The fluid should be allowed to drop from the needle into a sterile test-tube, which is then stoppered with cotton and allowed to stand for several hours, or until a strand of fibrin has formed; this occurs in from 1 to 6 hours, and it either settles to the bottom or reaches from the top of the fluid down to the bottom, spreading out in a fan-shaped delicate film. A straight platinum needle, not a loop, is touched to one edge of the fibrin, the adhesion being very firm; the fibrin is then transferred to a slide, care being taken to tip the test-tube so that the fibrin constantly floats in liquid; a few drops of the fluid are to be poured with the fibrin on to the slide, for, if the fibrin emerges for but an instant from the fluid, it will either roll up into a cord through which nothing can be seen or it will wrap itself so tightly around the platinum needle that it can not be detached; to prevent this, the edge of the test-tube should be flanged and not straight; when once on the slide and floating in the fluid, it can be carefully separated from the tip of the platinum needle with the help of an ordinary needle or pin; the excess of fluid is drained off from the slide and the remainder is evaporated by gentle heat, it being not only unnecessary but usually fatal to the success of the examination to press the fibrin between two slides; the film is fixed by heat, stained in the usual manner and then carefully gone over with a mechanical stage. A point for the protection of the examiner is worth mentioning; all of the germs are not caught in the fibrin, but some float free in the fluid, and it is well to flood the slide even to the risk of overflowing, a blotter or piece of filter-paper placed beneath the slide will absorb both the fluid and the stray germs, and disinfection is then easily accomplished by combustion; if the blotter is dark in color, the film of fibrin can then be seen much more easily and located on the slide. The next step in the examination is the taking of cultures; in the above series, cultures were obtained of pneumococci and of staphylococci twice each, all the other cultures remaining sterile. After the chemical examination, for which 5 c.c. will suffice, the remainder can be used for inoculation into guinea-pigs if this is deemed advisable; this is hardly necessary if tubercle bacilli have been found, but it is very desirable in all other cases and should be carried out, if possible, for then the exclusion of tuberculosis rests on unassailable ground; in but two of my non-tuberculous cases were inoculations made."

12. **Water Supplies.**—Bissell discusses the water supplies of cities and specially calls attention to the determination of the colon bacillus. The colon test properly made under certain conditions, he says, surpasses chemical means of analysis, both in delicacy and as an indicator of sewage pollution and is the greatest accessory in determining the relative degrees of safety under which a water supply may be used for household purposes.

16. **Rest and Septic Disease.**—Ochsner insists on the importance of absolute rest in septic infections, and he has become more and more impressed with the part which this element plays in the treatment. He says if complete rest is obtained by removal by gastric lavage of any food or mucus which may exist in the stomach, and then prohibiting the use of food and cathartics by the mouth, the inflammation will regularly remain circumscribed in the presence of gangrenous or perforative appendicitis, while it will as readily become diffuse if these precautions are not taken, unless at the same time the local cause of infection, the appendix, be removed and free drainage of the peritoneal cavity instituted. In other septic conditions it is also of value. He illustrates this by the result of strapping in the treatment of mastitis and the use of splints or plaster of paris casts in inflamed joints, strapping the chest in pleurisy, a dark room and bandaging of the eyes in conjunctivitis, etc. The element of rest should be borne in mind in the treatment of all forms of inflammatory conditions in any part of the body.

18. **Tetanus.**—The treatment of tetanus is reviewed and almost every form of medication used is shown to be ineffective. He asks, what are we to do in the case of tetanus? In the absence of any reliable remedy, and realizing the great fatality of the disease, it is only right that we should give the patient the benefit of every doubt and possibility. If there is a wound it must, of course, be thoroughly cleansed, and in rare cases and under certain conditions, amputation of a limb is advisable. The patient must be put in a darkened room and kept as quiet as possible. Antitoxin should be at once administered freely, and continued daily in large amounts, as frequently as the condition indicates. The hypodermic is the simplest method of administration, and probably as efficacious as any, though the intraspinal may be tried, if convenient. At the same time I would strongly recommend the hypodermic use of carbolic acid, as I know of no reason why the two methods of treatment should not be tried at the same time. Sedatives should be given freely, the amount being determined by the condition of the nervous system and their effect on the heart. Opium should never be omitted, the more powerful depressants being given as required; but in our efforts to allay the nervous irritability, we must be careful not to depress too much, as it is important to keep up the strength, especially in the chronic cases. During the convulsions inhalations of chloroform or amyl nitrite may be tried, but are not of much value, as during the spasms breathing is so greatly interfered with that very little of their vapor could reach the lungs. In some cases, late in the disease, stimulants may be indicated, though they should always be administered with caution, strychnia, of course, being avoided under all circumstances so long as the disease is in its active stages. During convalescence, it may be profitably employed. The question of feeding may come up and it is often impossible by the mouth and rectal feeding must be resorted to with hypodermoclysis of normal salt solution to relieve the thirst.

20. **Chronic Carbon Monoxid Poisoning.**—The dangers of coal gas or water gas are emphasized by Yarrow, who remarks that chronic monoxid poisoning occurs more frequently than is imagined, and is undoubtedly responsible for many obscure conditions which occur in the practice of every physician. The large consumption of gas for cooking purposes does not lessen the evil. He pleads for the more extensive use of the spectroscope in daily clinical work. The article contains reports of cases illustrating his views.

23. **Croupous Pneumonia.**—Hare and Dare in a study of the complications and sequelæ of croupous pneumonia independent of those from mechanical causes, conclude that they are best studied and classified as pneumococci infections. Their paper gives an arbitrary classification for easy remembrance. The series is composed of six classes as follows:

CLASS A.

Serous membranes	Pericardium....	Serous and purulent pericarditis.
	Pleura.........	Serous and purulent pleuritis and that affecting the diaphragmatic pleura.
	Endocardium...	Endocarditis. Malignant endocarditis. Ulcerative endocarditis, endocarditis with or without meningitis, or cerebrospinal meningitis.
	Synovial membranes..	Serous arthritis. Purulent arthritis. Osteo-arthritis.

The infection by the pneumococcus may cause pathologic changes in the central nervous system by the action of the toxins on the nerve centers.

CLASS B.

(*a*) Cerebral and cerebrospinal system....	Cerebral pneumonia. Meningitis. Meningitis due to pressure of exudate. Cerebrospinal meningitis. Hemiplegia. Paralysis. Cerebral abscess. Aphasia.
(*b*) Toxic action on the nerve centers.......	Delirium. Mania. Convulsions. Cardiac asthenia, resulting in delayed resolution, abscess and gangrene. Brachial neuritis. Bilateral polyneuritis. Trophic disturbances (herpes zoster). Temperature disturbances (hyperpyrexia) (subnormal ranges). Albuminuria and nephritis.
(*c*) Neurotic tendencies.	Retention of urine. Tetanoid and choreiform phenomena.

Changes in the blood and intravascular formations.

CLASS C.

(*a*) Intravascular (thrombosis and embolism)	Pulmonary gangrene, abscess and bronchiectasis. Spontaneous gangrene of lower extremities. Embolism of right lenticulo-optic arteries. Phlegmasia alba dolens. Renal and splenic emboli. Embolism of the brachial veins.
(*b*) Hemic changes....	Purpura hemorrhagica. Hemoglobinuria.

CLASS D.

Infection of glands and glandular structures.	Parotitis. Suppurative parotitis. Bronchial adenitis. Submaxillary adenitis. Thyroiditis. Orchitis. Ovaritis and abscess. Hepatitis.

CLASS E.

Infection of middle ear.	Otitis media. Purulent otitis media.

CLASS F.

From mechanical interference	Edematous laryngitis. Fatty tumor of right auricle. Jaundice. from obstruction of the bile-ducts. Dilatation of right heart from pulmonary obstructions (?) or toxic myocarditis. Delayed resolution and induration from cardiac asthenia.

24. **Color of the Feces.**—The normal feces are brown, of varying degrees of darkness, which are due largely to the bile pigment and are influenced by other causes such as digestive secretions, food residue, discharges from the intestinal wall and accidental ingredients such as drugs. The bile pigment is bilirubin, which in part is oxidized, either in the bile passages or soon after reaching the intestines, into biliverdin and several allied bodies. The pancreatic juice may have some influence, but not much under normal conditions. As a rule a vegetable diet produces much lighter colored stools than does a diet chiefly of meat. In infants the feces are of an orange-yellow color or that of the yolk of an egg. The intestinal discharges are mucus, pus, serum, blood, etc., which may modify the color, pus, for instance, giving a distinct yellow or yellow-greenish color; serum giving a straw-color where the usual fecal pigments are lacking as in cholera. Blood may make various changes in the color and certain articles of diet like cocoa, huckleberries, etc., may produce an appearance which may be easily mistaken for disorganized blood. Among the drugs Conner mentions are bismuth, which produces a blackish or dark green color due to bismuth oxydyl and not to bismuth sulphid as so commonly believed. The greenish stools attributed to calomel are not so frequent as supposed; a blackish-gray color occurs from iron, the yellow-colored from rhubarb, senna and santonin. The clay-colored stools of jaundice are well known, and he quotes Bunge as attributing this more to the presence of fat than to the absence of bile. Greenish stools are common in children but rare in adults excepting in certain cases of diarrhea, where Fleischer believes that they occur only when there is an inflammation with increased peristalsis of both small and large intestine and never when one or the other alone is involved, since in these cases either would have time for the reduction of biliverdin to hydro-bilirubin.

25. **Suture of the Liver.**—After we pass Glisson's capsule, according to Coffey, the softer structures of the liver have no more power to retain sutures to control and counteract blood pressure than so much mush. He thinks it of no use to apply sutures directly to the liver tissue for this purpose and employs a mattress suture where all the pressure comes on Glisson's capsule at three or four points. The pressure is all the time toward the center of the incision and obliterates all the space at the bottom. Two sutures are used, one being applicable to an incision which does not penetrate the liver entirely, and the other is applicable to wounds in which the liver is severed through and through. One he calls the Y-suture, the other the X-suture. The Y-suture is placed as follows: "A round curved needle, at least four inches long, armed with catgut or silk, is passed through the catgut support to the bottom of the incision, comes out on the other side, passes through another catgut support, re-enters through the support of the same side, goes back parallel to the other stitch and comes out through the support from which we started, making a quilt suture. A suture is then passed from the opposite side of the liver, either straight through or indirectly, as may be convenient, includes the two threads at the bottom of the cut in its loop, comes out on the bottom of the liver and again both ends passing through a single catgut weave are tied in the form of a quilt suture, thus drawing the other suture well into the bottom of the cut. The first suture is now tied and any amount of pressure can be used, for the line of pressure is not against the suture, but is on the catgut supports. Thus the bottom of the wound is brought in absolute apposition and any amount of pressure desired may be used. This may not bring the surface of the liver in as close contact as is desired, therefore, a second quilt suture is passed through the edges of the support, nearest the wound, simply taking in the capsule. In this way the tissues are absolutely brought in contact, and as much pressure can be brought to bear in closing a wound of the liver as in any other part of the body. In closing a wound of the liver which extends entirely through its substance, a modification must be used. Instead of the single suture which goes into the bottom of the liver, a second quilt stitch is passed through both sides on the bottom, the same as the Y-suture above, interlocking the two sutures to the center of the wound. In this way the pressure is brought to bear in a very effectual manner." The cuts which illustrate the article give a better idea of the suture than the description and the reader is referred to the original. Coffey says as far as he knows this method is entirely new, but he is conducting experiments on living animals to find the amount of catgut that will be absorbed. The *points which are original* are the use of the catgut weave for a support and the indirect or angular pressure made by a counter-traction suture. The needle should be round, full-curved and fully four inches long. The *one* with which the *counter-stitch is made* may be a simple darning-needle or any kind of a long straight needle.

29. **Prostatectomy.**—Thorndike remarks in favor of prostatectomy and reports a number of cases in which the suprapubic operation was performed. He gives the details of the procedure used from Fuller and sums up his conclusions as follows: 1. That great relief can be given to all patients

suffering from symptoms due to obstructing enlargement of the prostate, either by palliative or by operative means. . . . 2. That complete prostatectomy is always the operation of choice, because it is the only operative procedure which cures or gives uniformly good results, when successfully performed in proper cases. 3. That the best time for its performance is just as soon as palliative efforts have failed, or are manifestly impossible of execution, and before secondary changes in the bladder and kidneys, due to long-continued obstruction, have taken place. 4. That in those cases which come for surgical relief so late in the development of the pathologic conditions, that the bladders and kidneys are extensively diseased, and the patient is manifestly exhausted by long-continued suffering, other less certain and perhaps less severe measures may be advised, instead of a complete prostatectomy; but that such a decision can only be and must always be made by the surgeon for the individual case, and can not be made the subject of a generalization.

30. **Smallpox.**—The treatment of smallpox, of course, varies with the severity of the disease, and varioloid aside from the relation to the public need often cause but little inconvenience. Treatment is scarcely necessary, in many cases, but in the discrete or confluent smallpox, the indications for treatment are to preserve the patient's strength and relieve the skin manifestations. During the incubation period little is to be done, except to prevent anything that would debilitate. In the stage of invasion rest in bed is necessary, exclusion of solar light, use of tonics, phenacetin and other analgesics to relieve the headache, backache, etc., and ice for gastric irritation. Poultices or rubber bags filled with hot water applied to the stomach or back to relieve the distressing symptoms in these parts are contraindicated. Only easily digestible and good nutritious food should be employed. Stimulants are useful and agreeable adjuvants. Mild laxatives may be given in the early stage and continued if necessary. The pain and tenderness in the skin and the itching which develops are relieved by application to the parts of cloths wrung out of cold or hot water according to the patient's choice, and frequently changed. Gargles of chlorate of potash when the patient can use them are of benefit, but the greatest relief is obtained from a careful rinsing of the mouth by the nurse with a piece of clean old linen wrapped around her finger and previously dipped in a 1 to 20 per cent. solution of boric acid. The intense itching in the late pustular or suppurative stage is relieved by the mixture recommended by Dr. Hare: olive oil and lime water, equal parts, to which a little carbolic acid or thymoline is added. During the height of the secondary fever, the fever of suppuration, daily bichlorid sponge baths only can be given, as the patients are too sore and too much swollen to make feasible the giving of immersion baths. When suppuration and the secondary fever have subsided, and the crusts have fallen, the patient is given three thorough antiseptic baths at intervals of twenty-four hours. He then gets a clean, fresh suit of clothes and is removed to an uninfected part of the building. In the usually fatal hemorrhagic disease Kelly finds the remedies in regard to which there is most agreement among writers as to their efficiency are turpentine and ergot in liberal doses, carbonate of ammonium, quinin and the practice of transfusion.

31. **Placenta Previa.**—From statistics collected, Dorman draws the following conclusions: 1. That uterine relaxation and endometritis as important etiological factors are well shown; 2, that the immense variation in the types of bleeding should warn us to look on every bleeding at any time in pregnancy with suspicion; 3, that the very great possibility of sepsis should cause us to employ every precaution in asepsis. The necessity for exceptional care during the breech extraction, where the cervix is not completely dilated, is apparent. The cervix in this condition is unusually vascular and soft, and tears with fatal readiness. The chances are so great against the child that any eagerness to save it should not lead us to add risk to the mother's life. In connection with postpartum hemorrhage he mentions the danger of too great dilution of fluid by intravenous transfusion so that it will lose its power of clotting and the watery fluid will ooze through the tightest tampon. He therefore advises moderation in the amount of infusion. Repeated infusions of smaller amounts are preferable to one or two large ones. He suggests also the possible value of Cesarean section where the placenta is central or nearly so, the cervix rigid or undilated and the patient in a good condition, but this combination is very rarely found.

33. **The Southern Negro.**—According to Perry the southern negro is degenerating badly. He calls attention particularly to the prevalence of venereal diseases, showing that immorality is increasing. Tuberculosis is another disease which has become a scourge to the race, and it should be considered as almost entirely infected. The resistance to disease is lowered in the negro race. How much is due to these two causes is impossible to say. He thinks their part has been a major one. Insanity is next. In the last forty years the negro population of the state has been a little more than doubled, while the number of insane has increased twentyfold, the most rapid change that has ever been recorded in the history of any race. He finds little hereditary insanity existing at first, and attributes much of the physical and mental breakdown to the removal of healthy restraint and the tendency to migrate to cities and towns. In conclusion he notices the drug habits which he thinks are greatly increasing among the colored population of the towns, though the cocain habit seems to be decreasing since the law has taken the matter up. He mentions these facts as affecting the race as a whole, but not at all reflecting on honest negroes who are endeavoring to raise their race to a higher level.

43. **Hydrocephalus.**—Hunter has treated cases of hydrocephalus by opening through the dura, making a flap, and introducing a catgut ligature through the cortex into the lateral ventricles. After the first operation the improvement continued for six or eight weeks, but enlargement of the head increased and a second operation was performed. The child's condition was, therefore, as critical as it was at first, except the fever was lacking. He concludes that the reaccumulation of liquid was due to failure to secure a permanent opening between the ventricle and subdural space on account of the too rapid absorption of the very small ligature used in the first operation. He therefore used the larger No. 2 catgut, five strands, in his second operation, and with apparent perfect success. The child has now well-developed lower extremities and walks and runs about with other children two years after the operation.

45. **Nephropexy.**—The operation which is most satisfactory, according to Benjamin, is described by him as consisting mainly "in dissecting a strip of the fibrous capsule in a longitudinal direction, making two flaps, one at either pole of the kidney. When the dissection is made in this direction we shall have flaps long enough to bring up between the quadratus lumborum muscle fibers on either side of the wound and can fasten them in that position. The muscle fiber impinging upon these flaps gives additional support, and does not permit the sutures to cut through the capsule. When the flaps are dissected in the other direction, transversely, the flaps secured are very short and are of little avail as a support, for they are not long enough to bring up between the muscle fibers. The technic of the rest of the operation is about as described by other authors." He concludes as follows: "1. A certain percentage of prolapsed kidneys causes discomfort. 2. Prolapsed kidney often produces reflex symptoms. 3. Prolapsed kidney is often associated with various complications or dependent conditions. 4. Symptoms depending upon prolapsed kidney are frequently attributed to other sources. 5. The degree of prolapse does not always determine the proportionate amount of discomfort. 6. When the symptoms present have been traced conclusively to a prolapsed kidney, and when the suffering can not be relieved by pads or bandages, an operation should be advised. 7. The operation should be one which will anchor the kidney most securely in the position most comfortable to the patient. 8. The operation, properly performed, gives most satisfactory relief."

48. **Cholera.**—This number contains the report of Dr. T. R. Marshall to the Philippine Commission of Public Health on

Cholera, which seems to have been of an especially virulent type in the hospital reported from. Benzozone was used in some cases but found too irritating to the stomach in many others. Some advantage was obtained from rectal injections of normal salt solution and saline transfusions. He found that cases seen shortly after an attack and properly treated at home or removed to a hospital stood a chance of recovery, but a delay of five or six hours generally proved fatal.

49. **Rectus Advancement.**—The operation described in detail by Worth consists essentially in making two sutures, one above and one below on the muscle, both tied. One end of the thread is carried back, inserted through the muscle behind it and carried forward to near the corneal margin where it is brought out and again tied to the other end of the suture, left after tying the first. In this operation the central portion of the muscle is not constricted by suture and its main blood supply not interfered with. He says the immediate effect produced is the final result.

53. **Pathogenesis of Glaucoma.**—Troncoso holds from his statistics that the hypertension in glaucoma results from different exosmosis of aqueous which has thereby become more albuminous than normal, and in which vascular sclerosis is the principal factor. It occurs either as the result of a senile arteriosclerosis, or an arthritis, gout, etc., or as the result of localized endarteritis within the eyeball. The vessel walls become permeable to the albumin which, mixed with the contents of the anterior chamber, retards the proper filtration at the filtration angle. When the secretion of the albumin reaches a certain degree, the excretory passages still intact become insufficient, the intraocular tension rises until the augmentation of new aqueous equalizes the tension within the vessels, when secretion of aqueous is checked. Somewhat before this the first symptoms of glaucoma appear; the edema of the cornea, the moderate dilatation of the iris, the swelling of the retinal veins, the arterial pulsation, the periodic reduction of vision, the periorbital pains, etc., all phenomena dependent upon increased intraocular tension and venous stasis. Such attacks are nearly always associated with some mental emotion, a reflex congestion of the veins of the head, with insomnia, etc., producing a vasomotor dilatation showing itself chiefly in the vessels of the ciliary body. When these become severe, the disturbances progress by degrees until an acute attack of glaucoma breaks out. The amount of albumin increases, rapidly inhibits filtration and the tension rises. An intense congestion is produced in all the tissues of the eyeball accompanied by mild diapedesis (Knies). The cornea is infiltrated and becomes turbid, the iris is edematous, losing its normal appearance, its veins are dilated and tortuous, the uvea is copiously infiltrated. The vitreous presses forward the iris and lens and adds a new factor to encourage retention. He discusses the effect of iridectomy, myotics, complications of central and secondary glaucoma, and in conclusion reports experiments on rabbits with injections of albumin into the anterior chamber producing glaucomatous symptoms.

63. **The Criteria of Insanity.**—Abbot emphasizes the following points: "1. Insanity is a mental disease as shown by the criteria actually used in the determination of its presence or absence in the individual case; 2, the scientific study of insanity consists primarily in the study of the mental phenomena, not physical conditions; and 3, the study of physical conditions as possible causes is necessary, but loses a large part of its value unless the mental phenomena have been well studied, and of itself alone can never give us an understanding of insanity." The practical application of the paper lies in the fact that with modern scientific methods scientific psychiatric work can be done in the hospitals not equipped with laboratories.

64. **Typhoid Psychoses.**—These conditions are discussed at length and Farrar remarks in conclusion that typhoid fever attacking a sane person may leave him free of psychic disturbance or may give rise to all gradations of mental disease. That the severity of the symptoms do not necessarily stand in relation to the height of the fever or the severity of the infection and that subjects of psychopathic heredity are more prone to alienation, especially initial delirium, than those not thus burdened; that a protracted exhausting fever predisposes to an asthenic psychosis; that a second or third attack of typhoid is more likely to present mental troubles than the first. Of the special disease types the initial delirium is the rarest form, has the most rapid course and worst prognosis, over 50 per cent. ending fatally. It is essentially the expression of severe intoxication. The Nissl findings confirm this view. It often causes errors in the diagnosis and any case of mental derangement with fever justifies the suspicion of typhoid. The febrile psychoses are, of course, of the greatest frequency and afford the best outlook; that 25 per cent., however, persist for varying lengths of time into or after convalescence, and are especially due to the elevation of temperature and its consequences. The asthenic psychoses (excepting *conceptions délirantes isolées*, and cases of typical collapse delirium), have long weary courses and a doubtful outlook, with evidences of serious cerebral changes. They develop on a basis of exhaustion, anemia and malnutrition. There is, moreover, a post-typhoid predisposition (irritable weakness) which may develop late psychoses, with dubious prognosis. As a result of the metabolic revolution accompanying severe infections, it is observed that an attack of typhoid has been followed in many instances of so-called recoverable psychoses, by temporary improvement or recovery. Finally, he says that neither in their clinical or anatomical picture are typhoid psychoses distinguishable; that the elements of intoxication, infection, temperature, exhaustion, anemia, of whatever origin, may produce similar or indistinguishable appearances and that the determining factor of susceptibility to mental disorder, as well as of the course and event, may be expressed in a word as the mental reaction coefficient of the individual, together with its physical basis.

65. **Dementia Precox.**—The practical points in the diagnosis of this condition are the motor phenomena, such as tics, grimaces, impulsive movements, mannerisms, peculiarities of speech, etc. There is, the author thinks, a field that has not been fully investigated as yet in this line. One symptom noted by Kraepelin, but not emphasized by him, has been described by Dunton in a number of cases, that is, the mechanical irritability of the facial nerves which, when present and associated with mental aberration, is of diagnostic value. When the patient is tapped lightly with the percussion hammer over the cheek just in front of the ear, care being taken to exclude any visual impulse, there will be noticed a movement of the orbicularis palpebrarum varying in intensity from a marked contraction of the whole muscle, combined with other muscles, to a slight quiver of the inferior fibers. This phenomenon is quite different from that recently described by McCarthy, and Dunton hopes to investigate it more fully. The author specially points out the increase of the reflexes, which is common in this form of insanity and the tendency to sudden impulses, slow psychic reaction and silly purposeless resistance or negativism.

67. **Melancholia.**—Meyer reviews the cause of death in 36 cases of melancholia examined postmortem and calls attention particularly to a striking cell change mentioned by him in 1897 and which is practically the same as that described by Turner as characteristic of melancholia. In cases where this occurs the patients show resistance, rigidity, peculiar tetanoid attitudes of the extremities, frequent grimacing with the risus sardonicus, irregular twitchings and jactations appearing in exacerbations. The reflexes are generally exaggerated, rarely absent. There are no electric changes. The difficulty of coordination soon involves the deglutition and speech, and frequently diarrhea is noted with slight fluctuations of temperature. The mental condition is not easy to describe owing to the patient's condition, but he has been struck by the patient's ability to recognize the physician, even when hardly able to speak. While the symptom-complex may be of variable duration, occasionally only for a few days, followed by improvement with subsequent relapses, the end usually comes with bronchopneumonia or with death from infarction. The findings are much more extensive than Turner had supposed. Instead of being limited to the large cells of the cortex, they implicate many other large cell bodies, Clarke's columns, Deiter's

1. **Banti's Disease.**—After reporting three cases and calling attention to their special features, Barr remarks that his view of Banti's disease is that it is probably due to a vasomotor paresis of the splanchnic area, either in whole or in part, and that this paresis arises from disease of the visceral sympathetic ganglia. As a consequence there is great engorgement of the abdominal viscera, especially of the spleen and liver and increased hemolysis, with consequent oligochromemia and oligocythemia. The increased blood supply to these organs leads to fibrosis and lessened function. The peritoneal effusion when it takes place seems to be due to the vascularity rather than to portal obstruction. The paresis leads to retention of blood in the portal area with lessened supply to the rest of the body, fall in the general blood-pressure with lessened work for the heart, impairment of nutrition and muscular atrophy. The digestion is usually impaired and there is apt to be an increase of toxins in the intestinal tract with further aggravation of the mischief. The engorgement of the viscera and mucous membrane generally is a frequent source of hemorrhage. As regards splenectomy he says it may be an excellent treatment for the disease as has been recommended, but we have to treat the patient rather than the disease. It might start up leukemia in some cases, as difficult to treat as the disease itself. We must try to assist the spleen and to increase the leucocytes and get beyond this organ and reach the nerves and ganglia which supply the other viscera. We must try to raise the general blood-pressure, improve nutrition and keep the intestinal tract as aseptic as possible. For this purpose he prescribes salol, benzo-naphthol and occasionally a saline purge, and to raise the blood-pressure and affect the nerves he gives strychnin, digitalis, quinin and caffein. He thinks perchlorid of iron with chlorid of calcium is a good hematinic and vascular tonic; it also lessens the liability to hemorrhage. *A priori* he would not expect benefit from arsenic and in his first two cases he is trying suprarenal capsule. In the early stage the patient should be kept in bed and a large elastic abdominal belt firmly applied would probably do good. The diet should be light, simple and easily digestible. As there is not so much obstruction to the portal circulation as in an ordinary case of cirrhosis, there is not the same necessity for limiting the quantity of fluids drunk. He finds the following prescription a good method of introducing chlorid of calcium into the system: Take about an ounce of gelatin, the juice of one lemon, from two to four drams of chlorid of calcium and one pint of hot water. Dissolve the gelatin, etc., allow to set, and it is then ready for use. He prefers in the majority of cases drainage in preference to epiplopexy as suggested by Murrell and believes that for cases curable by epiplopexy the simpler means are just as effective.

5. **Pyloric Obstruction.**—Barker tabulates ten cases of pyloric obstruction or gastroduodenal ulcer treated by operation and discusses the conditions. All the cases had had careful medical treatment before surgical interference was suggested. In all the cases the operation was the retrocolic variety (v. Hacker), suturing the serous and mucous coats below the proposed opening and then opening the gut and stomach, uniting the resulting edges and finishing the continuous suture over the front which had been begun before the viscera had been opened. The abdominal wound was closed in every case except one by sutures, including all the layers with the skin. In the cases in which the buried sutures were used in addition to the skin sutures, the wound gaped on the tenth day after the skin sutures had been removed. The lymph was scraped off the edges of the wound and the edges wiped and the whole thickness of the abdominal wall sutured in one suture, the old buried suture removed at the same time, and the wound healed as thoroughly as if by first intention. All his patients were fed from the first by the mouth as well as by the rectum and the patients were allowed to keep in a semi-recumbent position while awake and were laid on their right side for sleep or change of position. He thinks there is advantage in this as it increases the capacity of the chest by the sinking down of the abdominal viscera and thus wards off to some extent lung trouble. In nearly every case he introduced a rubber tube into the stomach during the first twenty-four hours to relieve the organ of bile, mucus and blood and in all cases the relief was striking.

6. **Gastroenterostomy for Non-Malignant Gastric Disease.**—Dalziel reports the general results in thirty cases, only one of which was fatal, and describes his method. In the fatal case the death was probably due to complications, a very large ulcer destroying the stomach wall and exposing the pancreas.

7. **Intestinal Anastomosis.**—In order to obtain the best results from any bobbin for intestinal anastomosis it should possess the following qualities. It should be as Bishop says: 1. Easy of introduction; 2, perfectly simple and require no elaborate technic; 3, it should be resistant and absorbable; 4, it should be so made that the purse-string sutures which encircle the ends of the gut should, as they are tightened, approximate these ends by the mere act of tightening; 5, when in position it should present the folds of intestine which have to be united by a second line of suture in such a way as to facilitate that suturing; 6, it should be of such a size and shape as to protect the line of suture during the period of plastic union. He has tested the various bone bobbins that have been devised and finds that none of them combine all these advantages, and offers his own. He illustrates three forms respectively for enterectomy, gastroenterostomy-ileocolostomy and pylorectomy. The metal button has the advantage of rapidity of operation and can not entirely be superseded, but should not be used unless the element of time is of most importance.

8. **Filaria Perstans.**—The filariasis of Uganda has been studied by Cook, who finds that a high proportion of the Baganda living in the immediate neighborhood of the capitol harbor the embryos of the parasite Filaria perstans in their blood. The different classes of natives show varying infection-rates; the peasant class were most affected, 54 per cent., then the sick in the hospital, 48 per cent., and those who lived in the best hygienic surroundings fared best, the chiefs and Europeans' servants, 36 per cent. Some cases occur with absolutely no further symptoms of disease, and are frequently a great danger to the uninfected population from the increased difficulty of segregation of filariated individuals. The majority of cases, however, are accompanied by some at least of the earlier symptoms of sleeping sickness, and hence a connection between the two conditions is highly probable. A very high proportion of cases of sleeping sickness, if examined at the right stage, readily show the filaria in the peripheral blood stream—32 cases out of 34 examined in the Mengo hospital. Although Cook has not found that the severity of somnolence depends on the number of Filaria perstans in the blood, he thinks, as a rule, the number and severity of the earlier symptoms do vary with the number of embryos in the blood. Some other factor in addition to the presence of filaria in the blood is required to aid the diffusion both of filariasis and of sleeping sickness, otherwise the hospital in which cases both of filariasis and occasionally sleeping sickness have been introduced ought to act as a center of infection, which is not the case. Experiments ought to be carried out to determine what this factor is, that is, testing the various blood-sucking insects on filariated individuals, and determining, if possible, if they cause diffusion of filariasis and, if possible, determining how filariasis oversteps the boundary line that borders on the established disease of sleeping sickness.

23. **Peritonitis from Perforation in Typhoid Fever in Children.**—Méry recently operated on a child who presented symptoms of peritonitis the fifteenth day of an apparently mild case of typhoid fever. The perforation was found and sutured and the child recuperated, but succumbed twelve days later to broncho-pneumonia. The peritonitis was diffuse at the time of the intervention, but the autopsy disclosed that the inflammation had mostly subsided. The laparotomy was not decided upon until the twenty-first hour. If it had been done earlier, before the peritonitis had become so extensive, the child might have been saved. Chevalier has recently saved two out of three patients operated on promptly under these circumstances.

longer than two hours in the stomach, usually accompanied by simultaneous increase in the amount of fluids in the stomach. Or when considerable remains of a larger meal of meat, bread and vegetables are found in the stomach eight or nine hours afterwards. There is no other gastric affection in which such delay in the evacuation occurs constantly. The fluid food given to an ulcer patient stretches the stomach and drags it down. For this reason such patients should be kept in the dorsal decubitus or lying partially on the right side, with the pelvis elevated. This relieves the greater curvature, aids in the evacuation of the stomach and enables the food to be assimilated more rapidly, frequently fattening the patients. The enlargement of the uterus in pregnancy lifts up the greater curvature of the stomach in the same way, as if on a cushion, and thus mechanically relieves persons who have ulcers or ptosis of the viscera. After parturition the old symptoms return. He treats chronic ulcers by introducing into the stomach, after preliminary rinsing with a tepid boric acid solution, 200 gm. of linseed or poppy-seed oil containing 10 gm. of subgallate of bismuth (dermatol). This reduces the pain and improves the motor function. The oil alone is not so effective. It is indicated in all cases of not too advanced stenosis and without extreme, sack-shaped enlargement in which the oil might accumulate and fail to reach the ulcer.

56. Spinal Reflexes in Hysteria.—Steiner reports a case of uncomplicated traumatic hysteria which he has had under observation for years, in which the skin reflexes, the scrotum reflex in particular, is intact while the knee-jerk has disappeared. This is contrary to the text-books.

64. Etiology of Eczema.—Two children in one family became affected with extensive eczema. They were fed almost exclusively on milk from a single cow. On suspension of this milk the eczema rapidly healed. On resumption of the milk later it did not return. Investigation showed that at the time of the skin affection a large quantity of salt had been given the cow. When salt was again fed to the cow the eczema returned again, vanishing once more as the salt was discontinued. The eczema recurred later on one of the children when milk from a neighbor was purchased and again it was traced to an unusual amount of salt given the cows, and vanished on its suspension. No treatment was instituted at either time.

75. Action of Repeated Injection of Suprarenal Extract.—Samberger reports the results of a series of experiments on dogs repeatedly injected in a vein with about 5 c.c. of a 5 or 10 per cent. suprarenal extract. The aim was to approximately imitate the natural production of the suprarenal secretion and its influx into the circulation. The immediate effect after each injection was a remarkable pallor of all the visible mucosæ, maximal dilation of the pupils with loss of the reaction to light: the saliva streamed from the mouth and the temperature rose nearly a degree in three hours. Sugar appeared in the urine, but vanished again in twenty-four hours. The proportion sometimes amounted to 1.8 by the polarimeter. Exophthalmus was occasionally noticed. The respiration acquired something of the Cheyne-Stokes type. The gait became atactic and there was vomiting and incontinence of urine and spermatorrhea. The pulse was either much retarded or much accelerated. The secondary effect of the injections was a loss of appetite and weight, constipation or diarrhea and hypertrophy of the left ventricle. Some of the dogs succumbed after 8 c.c. of a 10 per cent. extract while others took 50 c.c. without disturbance beyond the symptoms mentioned above. After subcutaneous injection of the extract, edema and necrosis of the muscles developed at the spot and the animals suffered from apparently intense pruritus. In one instance severe hematuria followed a single subcutaneous injection. The animals became accustomed to the injections, the symptoms becoming comparatively attenuated after the first injection.

77. History of the Pulse in Medicine.—Zervos writes from Athens that Hippocrates was the first to note and describe the pulse, but Herophilus of Chalcedonia was the first to count it systematically. He lived about 300 B. C. and used a water clock for the pulse count. Galen's work on sphygmology is the best that has come down to us from antiquity. It is dated about 200 A. D.

78. The Foot Clonus in Recovery from Cerebral Hemorrhage.—Fragstein has had occasion to observe nine cases of men between 35 and 43, all with a history of syphilitic infection five to eight years before hemiplegia developed. The hemiplegia had passed away in all cases, the functions of the limbs were apparently normal in every respect, yet the foot clonus described by Westphal as a sign of cerebral hemorrhage or other lesion, still persisted unattenuated. The center that presided over the function was apparently restored to normal, but the function of the inhibiting center was evidently still deranged.

81. Pancreas Diabetes and Icterus Gravis.—Teleky has observed two cases of an affection in men of 50 which commenced with mellituria impossible to banish completely even on a strict diabetic diet. Icterus developed a few weeks afterward and on its appearance the sugar vanished permanently from the urine. The fat ingested was not utilized in the system to the normal amount and in both cases the icterus persisted until death which followed after a few months of progressive symptoms of chronic pancreatitis. In both the autopsy showed that the pancreas was the seat of profound pathologic alterations while the other organs were almost completely normal. In both cases the cause of the severe icterus was evident in the compression of the choledochus by the enlarged pancreas. The cases suggest that in future when icterus is observed accompanying or subsequent to mellituria, and the stools contain undigested fat, the possibility of pancreatitis should be borne in mind. If the icterus persists and is not accompanied by symptoms indicating gallstones, the icterus can be attributed to compression of the choledochus by the inflamed pancreas. If the icterus can be controlled by a choledocho- or cholecysto-enterostomy, the life of the patient may be prolonged. Surgical intervention should be early in such cases, without wasting time on useless medical measures.

84. Etiology of Alimentary Glycosuria.—Schlesinger describes experimental research which has established among other facts that alimentary glycosuria after ingestion of dextrose occurs exclusively by way of rapid absorption through the thoracic duct. His clinical and experimental experience further indicates that any injury of the liver has a tendency to induce alimentary glycosuria. The disturbance is not very pronounced so far as levulose and starches are concerned, and a second, re-enforcing factor must intervene before diabetes results. This factor may be what Naunyn calls congenital weakness of sugar metabolism, a hereditary tendency. It is also possible that an affection of some other organ, superposed on the first, may be sufficient to induce the diabetes which neither alone could accomplish. Naunyn is probably correct in the assumption that very pronounced alimentary glycosuria is suspicious of diabetes. Schlesinger found that dextrose was eliminated after ingestion of levulose in 2 cases of acromegaly, whose relationship to diabetes is generally recognized. The patients were free from sugar on ordinary diet, but on ingestion of 100 gm. dextrose their urine contained a large proportion of sugar, and after ingestion of levulose, first this sugar and then dextrose. His work emphasizes the importance of the absorption in the thoracic duct and of any disturbance in the liver function as factors in the etiology of diabetes.

89. Yeast in Therapeutics.—Paschkis has used yeast in about 20 cases of furunculosis, acne or severe folliculitis, and found that its therapeutic action was remarkably effective in some of the cases while others proved refractory. Brocq claims that it is as much of a specific in furunculosis as quinin in malaria or mercury in syphilis. There are no inconveniences from its use except that possibly if much sugar is being taken at the same time, the fermentation set up might induce considerable flatulency.

106. Mechanism of Agglutination.—Joos believes that he has finally established that agglutination is a chemical reaction, and that a true combination results which terminates in the formation of a new substance. Agglutination is the result of the combination of three substances, two of which are specific and the third is merely a minute quantity of some salt. The intensity of the reaction is determined by the particular salt present. The combination of the specific agglutinator with the agglutinatable substance produces the combination, but it is invisible to the eye or microscope and the bacilli remain alive, free and motile, until the salt is added. This causes precipitation at once, the salt entering into the combination. The properties of the new substance thus formed differ from those of its constituents. The trifle of salt needed may be supplied by the bodies of the bacteria. The phenomenon of agglutination, on the whole, he concludes, is very much like that of the production of a double salt.

107. **Neutralizing Property of Brain Tissue in Regard to Tetanus Toxin.**—In the experiments related the effect on the tetanus toxin *in vitro* of an emulsion of the brains of guinea-pigs proved to be identical with the action of antitoxin. This justifies the assumption that the action of guinea-pigs' brains and of antitoxin is essentially equivalent in this respect.

112. **Cerebellar Anomalies.**—Della Rovere and De Vecchi report a case of hitherto undescribed anomaly of the cerebellum consisting in separation of the posterior vermis by exaggeration of the curve between the superior and inferior portions and resulting in an anomaly of a body resembling a minute cerebellum resting on the after portion of the medulla.

113. **Functions of the Thyroid.**—Coronedi and Marchetti report experiments on dogs in which they had removed the thyroid and parathyroid bodies. They fed them with iodin and bromin preparations in fatty excipients with the result of relieving the strumapriva symptoms to a greater or less extent. Without formulating conclusions they remark that the salutary effect of halogens thus administered in animals after removal of the thyroid and parathyroid bodies indicates that there is some special action of these substances that render them a substitution to a certain extent of the thyro-parathyroid tissues, and that the experiments contribute valuable aid to our knowledge of the physiologic effects of bromin and iodin in the thyro-parathyroid apparatus.

114. **Exophthalmic Goiter.**—Tedeschi alludes to his former contribution abstracted in The Journal, vol. xxxviii, p. 1187, and reports additional experiments from which he deduces the following conclusions: 1. In animals, a lesion of the restiform bodies, especially the anterior portion, evidently causes the Basedowan syndrome. 2. In animals thus affected, but in which the symptoms have diminished or disappeared, it is possible to reawaken them in whole or in part by producing in them hyperthyroidization. 3. In animals in whom the thyroid apparatus has been removed almost totally the section of the restiform bodies does not cause the Basedowan symptoms. 4. In animals in whom the Basedowan symptoms have just been produced by loss of the restiform bodies, the removal of the thyroid gland diminishes or completely banishes the greater part or all of the symptoms.

115. **Acute Confusional Insanity.**—Camia has studied his personal observations and cases from the literature as regards the pathologic findings in acute confusional insanity. He finds the pathologic anatomy does not clear up the pathogenesis in many of the cases. Among the factors that cause acute confusional psychoses there is only one that seems to be common to the majority, perhaps to all. This consists in a special slight alteration of the organic chemism (changes in chromatin, etc.) which may depend on causes of various nature.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Aug. 21 to 27, 1902, inclusive:

Henry L. Brown, contract surgeon, detailed a member of an examining board at Fort Sheridan, Ill., vice Contract Surgeon Charles F. Smith, relieved.

Alpha M. Chase, contract surgeon, now at Fort Assiniboine, Mont., to report for duty at Fort Reno, Okla.

William M. Gray, major and surgeon, U. S. A., on being relieved from duty at Fort Thomas, Ky., to report for duty at Fort McPherson, Ga.

Gustavus I. Hogue, contract surgeon, now at San Francisco, to report for assignment in the Department of California.

Harry C. Marcy, contract surgeon, now under orders to accompany troops to Fort Slocum, N. Y., will, on his arrival at that post, proceed to Fort Riley, Kan., for duty.

Lewis B. Porter, contract surgeon, now at San Francisco, to report for assignment in the Department of California.

Harry S. Purnell, lieutenant and asst.-surgeon, U. S. A., detailed a member of an examining board at Columbus Barracks, Ohio, vice Major Guy L. Edie, surgeon, U. S. A., relieved.

Edward Sears, contract surgeon, now at Fort Niobrara, Neb., is assigned to duty at that post.

John M. Shepherd, contract surgeon, leave of absence extended one month.

Allen M. Smith, captain and asst.-surgeon, U. S. A., leave of absence for fifteen days granted, to take effect about Sept. 1, 1902.

Edwin P. Tignor, contract surgeon, leave of absence from the Department of the Missouri extended ten days.

George H. Torney, major and surgeon, U. S. A., to proceed to Little Rock, Ark., to confer with the U. S. attorney for the Eastern District of Arkansas on business pertaining to the Hot Springs reservation and on the completion of this business to return to his proper station, the Army and Navy General Hospital, Hot Springs, Ark.

William J. Wakeman, major and surgeon, U. S. A., former orders amended so as to direct him to proceed to Fort Thomas, Ky., to relieve Major William W. Gray, surgeon, U. S. A.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending August 30:

P. A. Surgeon W. H. Bell, detached from the *Chesapeake,* and ordered to duty as a member and recorder of a Board of Medical Officers, Naval Academy, Annapolis, Md., and thence home and to wait orders.

P. A. Surgeon F. L. Benton, part of order of May 27, detaching from *Columbia,* revoked.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Aug. 30, 1902:

SMALLPOX—UNITED STATES.

California: San Francisco, Aug. 10-17, 8 cases.

Colorado: Denver, Aug. 8-16, 1 case.

Illinois: Chicago, Aug. 16-23, 4 cases.

Indiana: Indianapolis, Aug 16-23, 3 cases.

Louisiana: Shreveport, Aug. 16-23, 3 cases.

Massachusetts: Aug. 16-23, Boston, 8 cases, 3 deaths; Cambridge, 1 death; Lawrence, 2 cases.

Missouri: St. Joseph, Aug. 16-23, 16 cases; St. Louis, Aug. 17-24, 1 case.

Nebraska: Omaha, Aug. 16-23, 4 cases.

New Hampshire: Manchester, Aug. 16-23, 1 case.

New Jersey: Camden, Aug 16-23, 3 cases; Jersey City, Aug. 17-24, 1 case; Newark, Aug. 16-23, 6 cases; Passaic, July 26-Aug. 23, 2 cases.

New York: Buffalo, Aug. 16-18, 4 cases; New York, Aug. 18-25, 5 cases, 1 death.

Ohio: Cleveland, Aug. 16-23, 50 cases, 8 deaths.

Pennsylvania: Aug. 16-23, Allegheny, 2 cases; Altoona, 1 case; Erie, 6 cases; Johnstown, 4 cases; McKeesport, 3 cases; Philadelphia, 3 cases; Pittsburg, 9 cases, 1 death.

South Dakota: Sioux Falls, Aug. 16-23, 1 case.

Utah: Salt Lake City, Aug. 16-23, 1 case.

Wisconsin: Milwaukee, Aug. 19-26, 1 case.

SMALLPOX—FOREIGN.

Canada: Quebec, July 26-Aug. 16, 3 cases.

Great Britain: Dublin, Aug. 2-9, 1 case; Glasgow, Aug. 8-15, 1 case; Leith, Aug. 2-9, 1 case; London, Aug. 2-9, 21 cases, 4 deaths.

India: Bombay, July 22-29, 8 deaths; Calcutta, July 19-26, 1 death; Karachi, July 20-27, 1 case, 1 death.

Russia: Odessa, Aug. 2-9, 4 cases.

YELLOW FEVER.

Brazil: Amazon Valley, July 24, raging.

Colombia: Panama, Aug. 11-18, 3 cases, 1 death.

Dutch Guiana: Paramaribo, July 1-30, 1 case, 1 death.

Mexico: Coatzacoalcos, Aug. 8-16, 9 cases, 2 deaths; Vera Cruz, Aug. 8-23, 39 cases, 17 deaths.

PLAGUE.

Egypt: Alexandria, April 14-Aug. 6, 70 cases, 35 deaths; Tukh District, May 2-Aug. 6, 39 cases, 21 deaths.

India: Bombay, July 22-29, 28 deaths; Calcutta, July 19-26, 12 deaths; Karachi, July 20-27, 20 cases, 15 deaths.

Russia: Odessa, July 26, officially announced.

CHOLERA.

China: Niuschwang, July 5-12, 98 cases, 81 deaths; Tientsin, June 30-July 14, 190 cases, 110 deaths.

Egypt: General, July 15-Aug. 6, 981 cases, 819 deaths; Alexandria, to Aug. 6, 5 cases, 4 deaths; Assiout District, including Moucha, July 5-Aug. 6, 459 cases, 372 deaths; Cairo, July 22-Aug. 6, 464 cases, 404 deaths.

India: Bombay, July 22-29, 4 deaths; Calcutta, July 19-26, 34 deaths; Karachi, July 20-27, 25 cases, 24 deaths.

Japan: Fukuoka Ken, to July 28, 287 cases, 168 deaths; Hiogo Ken, July 29, present; Kanagawa Ken, July 29, 1 case; Kumamoto, July 29, present; Nagasaki, July 29, present; Saga Ken, July 29, present; Tokyo Fu, July 29, 3 cases.

Address.

SURGERY OF TUBERCULAR CAVITIES OF THE APEX OF THE LUNG.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON SURGERY AND ANATOMY, AT THE FIFTY-THIRD ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, AT SARATOGA SPRINGS, N. Y., JUNE 10-13, 1902.

DE FOREST WILLARD, M.D.
SURGEON PRESBYTERIAN HOSPITAL.
PHILADELPHIA.

When I commenced, a year ago, the experimental work intended to be my contribution to our symposium on "Tuberculosis of the Soft Parts," selected for discussion before this section, it was my hope that I should be able to add something of practical and personal importance to the subject in its relation to human lung surgery. Unfortunately, I am obliged to report that I have been unable to induce any patient to submit to the operation of pneumonectomy or pneumonotomy for tuberculous cavities in the lung. Individuals in the early stages, at the time when operation would be most helpful, have naturally declined it, considering it unnecessarily serious; while those seen by me in the later stages have been too far advanced for me to conscientiously recommend operative procedures.

For many years it has been my expectation and hope that we should be able to treat and eradicate local tuberculosis of the lungs as we eradicate local tuberculosis in the joints and in other tissues. The anatomic and surgical difficulties to be encountered in invasion of the chest are, however, far greater than in any other region, even the brain and abdomen, which must account for the slow advance that has been made in lung surgery. A few brilliant results have been reported, but I regret to say that the majority of operative procedures have not prolonged life, while in many instances existence has been shortened.

OBSTACLES TO OPERATION.

The difficulties in entering the thoracic cavity are due to the fact that respiration is a vital function, which is both important and immediate and which can not be interfered with even for two minutes without serious menace to or even loss of life, while in both abdominal and in cranial surgery the interference is with functions by no means so immediately concerned with existence. The moment that external air pressure of fifteen pounds to the square inch is admitted outside a healthy lung the symptoms of dyspnea in the majority of cases become so profound and alarming that operative procedures must be suspended, and the entire efforts of the surgeon directed to the immediate continuance of respiration. The expansile function of the lungs, the movement of the mediastinal partition of the thoracic walls and of the diaphragm are all concerned, and while the condition is temporarily improved by closure of the wound, yet the air hunger is still great, and unless the Fell O'Dwyer, or other form of artificial or respiratory apparatus is at hand, life may be lost. In a few cases, which can not be explained, these symptoms do not occur either in the human being or in dogs, but they are so rare that the surgeon can not expect to meet them in a given case. Of course, in disease, conditions are different and the admission of air is a less serious matter, the previously compressed lung, or one that is bound to the chest wall, being much less liable to collapse. The anchoring of the lung to the chest wall, either artificially or by disease, not only prevents collapse when air is admitted, but also retains the mediastinal partition in position, and prevents interference with the movements of the opposite lung.

The experiments below enumerated were undertaken in an attempt to discover the possibility of the successful drainage of tubercular cavities in the lung, but it was found that in artificially induced tuberculosis the tendency was to promote general infiltration, and the time required to produce cavities was so long that the experiments were impracticable. I was therefore obliged to content myself with an investigation of the susceptibility of the animal to pneumonectomy and pneumonotomy, together with improvement in the technic of promoting adhesions of the pleural surfaces before making the incision.

It is not my purpose to touch at all on the question of gangrene of the lung, or abscess, or bronchiectasis, or any of the conditions other than tubercular cavities, since time does not permit.

In my experience, even cavities that form in the middle and lower lobes posteriorly are usually the result of previous pneumococcic infection, the abscess and the tubercular infection being later results. These are the cases that are almost uniformly successful under pneumonotomy. They should be classified by themselves, since, although sometimes tubercular, they differ decidedly in their prognosis from tubercular cavities in the apex. Many cases of abscess and gangrene following pneumonia in the lower lobe are mistaken for tuberculosis.

THE VARIOUS OPERATIONS PERFORMED.

The operations practiced for the relief of tubercular cavities of the lungs are:

1. Compression of the lung by the injection of nitrogen or other sterile gas into the pleural cavity.
2. Removal of ribs to permit collapse of chest wall and consequent compression of lung.

3. Counter-irritation by cautery.
4. Aspiration and the injection of medicated solutions.
5. Incision and drainage of the cavity—pneumonotomy.
6. Excision of the diseased area—pneumonectomy.

NITROGEN INJECTIONS.

Compression of the lung by the injection of nitrogen or other gas into the pleural cavity for the purpose of collapsing the lung and thereby giving rest to the organ until healing of the cavity has occurred was advocated by Murphy before the Association in 1898, but statistics are yet too few to form a rational basis for decision as to its merits. Compression of the lung favors fibrosis, cicatrization and occlusion of lymph channels and blood vessels. Lemke[1] has published a number of articles which show excellent results, and he will present further arguments in a paper to be read in the Section on Practice of Medicine at this meeting. His conclusions are that the method is helpful in arresting pulmonary hemorrhage and in hastening cavity cicatrization. His average injection is 120 cu. in. every three or four weeks.

COMPRESSION BY REMOVAL OF RIBS.

Allis,[2] Porritt, Ferguson, Berliner, Spengler and others have recommended the compression of the lung and the reduction of lung space by the removal of a portion of the ribs, either in front or behind, or both. The latter adds local treatment by iodoform to the procedure. Bloch immobilized the chest for pulmonary tuberculosis by a plaster jacket on the diseased side, with great relief to the cough and improvement of symptoms.

COUNTER-IRRITATION.

Vidal has tried the effect of thorough counter-irritation, treating forty-four cases by the actual cautery applied to the chest wall over the diseased area. He reports thirty-seven good results and believes that the procedure in the early stages is curative, and in the later stages beneficial. He attributes the results to compensatory congestion and to the increased nutrition of the organ called forth reflexly. Cough and expectoration are lessened and general condition improved.

INJECTION OF MEDICATION.

Aspiration and the injection of medicated solutions advocated by Baglivi in the 16th century, and practiced by Hastings and Storcks in the 18th, and also by Mosler, was revived by Pepper[3] and others about 1873-4. These injections were used as many as forty times in some cases. They were not unattended by danger, and the results have not been favorable. The substances employed have been iodin 10 per cent., carbolic acid, iodid of potassium, bichlorid of mercury, iodoform, nitrate of silver, etc. Tracheal injections and vapors of creosote, menthol, etc., have also been employed.

INCISION AND DRAINAGE.

Pneumonotomy has for several centuries been recognized as among the legitimate operations for attacking cavities in the lungs, notice having first been attracted to its value by the occasional occurrences in duelling, when lung cavities were opened by thrusts of swords, with recovery following. The operation was done with definite surgical purpose as far back as 1643 by Baglivi, and has been revived at periods since that time, as the tables appended to this report show. Valuable work has been done in this country by Park, Wills, Murphy and others. The percentage of cures does not show any marked increase over those treated along hygienic and dietetic lines. There is no question but that certain cases are markedly benefited temporarily, especially where the infection is mixed, and where both tubercular and streptococcic infections were present in cavities draining imperfectly through the bronchi. The retained secretions rapidly infect the individual and produce those symptoms familiarly known as hectic. The greatest advantage of the operation would be secured by *early drainage*, but, as stated at the beginning of my article, these are the cases which decline the operation, and in whom also the surgeon is loath to urge its performance. In the later stages there is, of course, far less benefit to be expected, as it is hardly probable that the focus is single, or that the entire diseased area can be reached. In these cases, however, marked benefit does occur from the lessening of the cough and the lowering of the temperature, and the increased comfort and strength given to the patient.

The important preliminary step is the accurate locating of the cavity by auscultation, percussion and the use of the *x*-ray. This latter, while of value, is not positive, and benefit to diagnosis is relative. It is not a certain guide; nevertheless, it is of advantage, as it sometimes gives a shadow at the site of the focus.

TECHNIC OF PNEUMONOTOMY.

Chloroform is the best anesthetic and need be given but in small amount; in fact, after the external tissues are divided, but little pain will be experienced. Some patients who bear pain well will get on admirably with local anesthesia. An incision should be made from the *sternum outward in the line of the second interspace*, or over the accurately located diseased focus. As a rule, it is better to excise a couple of inches of one or two ribs, which should be done cautiously and subperiosteally, so that the pleura is uninjured. Some operators go directly through the interosseous space and omit the rib resection, but unless the surgeon is certain that adhesions exist, it is best to have good room for manipulation. After resection, it is sometimes possible to observe through this intervening membrane the movements of the lung, and to determine the very important question of adhesions; upon these adhesions will depend largely the success of the operation. If the cavity can be reached without the admission of air into the pleura, and without the risk of infecting the pleura with the tubercular discharge, two very positive advantages have been secured and the operation becomes a simple one, practically little more than the opening of an abscess. If the pleura is thin, transparent and lustrous, the lung is not adherent; if dense and gray, the layers are probably in contact. An aspirating needle can now be introduced; if the point of the needle moves but slightly, adhesions are present. Murphy has advised the injection of *sterile air or nitrogen into the pleural cavity*; if there are no adhesions, each inspiration will suck in more air, and the lung will collapse, while if adhesions exist, the respiratory conditions will not change. Shapesko uses an exploratory needle connected with a manometer; if the needle enters an open space, the register is lowered; if there are cavities, it remains stationary. If *adhesions are not present*, it is always well to delay the operation and endeavor to secure the apposition of the two pleural layers. This I have been able to accomplish in twenty-four hours by carrying catgut sutures with a handled perineal needle, long and with a sharp curve, through the interosseous space, and through the superficial portion of the lung for an inch and a half or more. Four sutures are thus placed in a parallelogram. say one and a half inches wide by two inches long. They are then tied just sufficiently firmly to bring the two layers of the pleura in apposition, but not to strangulate the tissues. In my experience twenty-four to forty-eight hours are long enough to secure adhesions. Chlorid of zinc applied by tampon or by paste is sometimes employed to produce adhesions, but is slow in action. Agar-agar has also been injected into the pleural cavity to fix the lung and produce a new cell formation like connective tissue.

[2] Trans. Penn. State Med. Soc., 1891.
[3] Pepper: Trans. Amer. Med. Asso., 1880, xxi, 239.

I have never had an accident by the suturing method except once in experimental work, when the needle evidently passed through a good-sized pulmonary vein and then through a bronchiole. The dog collapsed, showed bloody expectoration and died immediately. The postmortem showed that the bronchioles were filled with blood and the heart with air. This accident adds another to the dangers already reported.

Fortunately, in tubercular cases the lung is usually adherent. If the lung is not adherent, there is danger of pneumothorax and empyema, both of which conditions are exceedingly grave. The wound being left open. the operation may be completed on the second or third day under cocain by an incision along the center of the parallelogram. An aspirating needle may be introduced to find the cavity, the incision being then made along the canula as a guide, either with knife or cautery, according to the choice of the surgeon. If the cavity is deep, of course the latter is less likely to produce hemorrhage from intervening vessels, especially if the lung tissues are soft.

Palpation of the lung substance may discover the site of the abscess, if the aspirator has not been successful, and the finger or a pair of blunt forceps may be used to reach the cavity. Great care must be exercised not to break up pleural adhesions. Once the pus is reached the canal can be dilated by a pair of strong forceps or the finger, and the cavity thoroughly mopped, not irrigated. As there is usually sufficient irritation arising from the operation, it is not well to apply any caustic or any other application to the wall of the abscess. Should a hemorrhage be started, the part should be closely packed with sterile aristolated gauze, which may remain in place for forty-eight hours. If hemorrhage is not severe a rubber or gauze drain may be at once inserted. Irrigations are inadvisable, as material may be carried into the other bronchi, increasing the danger of bronchopneumonia. Where a considerable depth of lung tissue has been perforated in order to reach the abscess, it is well to mop the fresh area with chlorid of zinc solution, five grains to the ounce, in order to prevent fresh infection of lymph spaces from the pus. There will be a slight rise in temperature for a few days after the operation and cough will be increased.

To prevent atelectasis or collapse of the lung, sterile water or air may be slowly injected in advance into the pleural cavity. If collapse occurs the opening may be hastily closed by tamponing with gauze or the finger, and intrapulmonary pressure increased by an artificial respiration apparatus. The lung also may be grasped, brought into the wound and fixed with sutures.

The leakage of air into the pleural cavity from a bronchus that has been opened by ulceration is not as serious in the production of pneumothorax as is the case in a fresh wound of the bronchus. This is well illustrated by a series of experiments that I have reported,[4] where, after an incision of the bronchus, the efforts at respiration after the closure of the wound tended constantly to increase the quantity of air outside the lung, its re-entrance into the air passages being prevented by valve action due to the tubular shape of the bronchus. In a wound of the bronchus, moreover, increased intrapulmonary pressure by a Fell O'Dwyer or other respiratory apparatus would tend to increase the pneumothorax.

Wills[5] has operated on two cases of lower lobe abscess. The first man had had pleurisy, and presented signs of a cavity in the left lower lobe posteriorly below the scapula. Also showed signs of consolidation at apex. Each morning vomited a pint of pus; had night sweats, tubercle bacilli and elastic fibers were found microscopically. The sixth rib was excised in the anterior axillary line, where there was redness and signs of pointing. On opening the pleural cavity the patient collapsed, and the operation was obliged to be suspended. A drainage tube was placed in the pleural cavity. On the ninth day the abscess burst, and fetid gangrenous pus poured from the wound and through an opening in the bronchus. The wound was drained and the man sent into a healthy mountainous region. In five months cough and expectoration ceased; twenty months afterward no sign of abscess, was working hard, and gained seventy-five pounds; has since continued well and strong. This was one of the class of cases which I have already enumerated as being more hopeful than cavities of the apex.

Wills' second case had had pleurisy twice. Cavity in right lung posteriorly. Tubercle bacilli found in sputum. Two inches of the eighth and ninth ribs were excised posteriorly. There was partial adhesion of two layers of the pleura, but no pus in the pleural cavity. Wills[6] speaks very favorably of his result in the first case, and advises the operation, especially when septic symptoms are due to imperfect drainage through the bronchi. He believes that it is good, conservative surgery, saving life and giving comfort. Porritt advises that the cavity of the apex be reached from behind, not in front, incision being made above the scapula and portions of the second and third ribs resected. In 50 tuberculous autopsies at the Philadelphia hospital, the adhesions were found both in front and behind the apex in 33 cases; in front, 10; behind, 7. Tuffier, who has had experience with pneumonotomy, considers the dangers great when there are no adhesions, and has been compelled by pneumothorax to abandon his operations in 8 cases; 2 died immediately; in 2 the focus was not reached; one recovered from the operation, and was again subjected to operation two months later; in only one case was the focus reached at the time of operation. Sonnenburg from his experience also emphasizes the dangers both from pneumothorax and from hemorrhage.

EXCISION OR PNEUMONECTOMY.

Excision of a portion or the whole of the lung has been successfully tried, both experimentally and in the human subject. Tuffier reports a successful case of removal of a consolidated apex, with the patient living four years later in good health. Doyen and Lowson also report successful cases. Ferguson operated on one patient three times: first, opened abscess; second, excised ribs; third, pneumonectomy; final result, apparent cure. Ruggi also had 2 cases, both died. Hofmokl records 5 cases of pneumonectomy, the apex removed in two cases; both died quickly. Bloch[7] excised at one operation both tubercular apices. The patient died on the table and Bloch, being censured by the coroner, committed suicide.

[6] THE JOURNAL A. M. A., Jan. 5, 1901.

The chief dangers are pneumothorax, hemorrhage and the tearing of other thoracic organs. If there are no adhesions, the lung must be quickly grasped, drawn into the opening and sutured around the margin.

My own experiments, detailed in this paper and in other places,[8] as well as those of many others, show that considerable portions or even the entire lung may be excised, ligated, cut or cauterized off, and the stump returned to the cavity without serious injury to the animal, but unless the operations are done with thoroughly antiseptic precautions, gangrene or empyema are likely to result. A dog is so likely to die under anesthesia, and pneumothorax is so serious a condition with his defective mediastinum, that the best technic seems to be a rapid incision after resection of the ribs, then grasp and drag the lung into the opening, stitch the pleura and lung with catgut, ligate firmly, put in a catgut drain, suture the skin, cover with sterile gauze and apply plaster of paris girdle. By this method the stump in the lung will heal in the wound without pleurisy, and the remainder of the lung will remain active, as the pneumothorax is relieved.

Rabbits have survived completely after excision of an entire lung; human beings doubtless would not. Wills[9] did ten pneumonectomies on rabbits, most of them suffering but little from the operation. Zaharowitch also had fair results, as did Patek and Sailer. Biondi performed pneumonectomies on sixty-three animals, all of which recovered after excision, and Ricketts has had excellent results in his many experiments covering the whole field of lung surgery.

STATISTICS OF PNEUMONECTOMY.

Salomoni reports 2 favorable cases; one lived four years, dying of tubercular peritonitis; another two years, death from tubercular meningitis. He records 38 pneumonotomies for tuberculosis; 28 cured, 8 deaths, 2 doubtful. De Cérenville 4 cases of pneumonotomy; 3 deaths. Poirier and Jonnesco in the Paris Congress of Tuberculosis, 1891, reported 29 cases of incision and drainage of tubercular apices; 4 cured, 15 improved, 9 deaths, 1 unknown. Sonnenburg 4 operations, 1 cure, 3 deaths. Hofmokl 5 pneumonectomies. Kronlein 2 pneumonectomies. Groux of Brussels is reported by Bouchout to have had 13 pneumonotomies many years ago. Heydweiller collected 42 cases; 23 deaths, 15 improved, 4 relative cures, 45 per cent. recoveries. Ricketts' collection shows after operation in tubercular cases 60 per cent. recoveries, indicating that surgery of the lung is beneficial. Trzebicky's collection of 24 operations on tubercular cavities gives 5 complete cures (1 living three years after operation), 5 not healed, 9 deaths, 5 results not known. Tuffier, 8 cases pneumonotomy; 2 died immediately, 1 in a few hours, in 2 the focus was not reached, 1 recovered, focus opened four months later. and in one only was the focus reached at the time of operation. He collected 26 pneumonotomies for tubercular cavities; 13 recoveries, 13 deaths; 50 per cent. recoveries. Pneumonectomy, 1 death, puncture 1 case, 1 recovery. Thoracoplasty 3 cases; 2 recoveries, 1 death. Incision of additional abscesses, 5 operations; 4 recoveries, 1 death. Total, 36 cases; 20 recoveries, 16 deaths. Tuffier in his address at the Moscow congress records 306 pneumonotomies for all forms of lung abscess, chiefly gangrene; 217 cured, 88 died, 71 per cent. recoveries.[10] Murphy's[11] statistics show 47 cases of tuberculosis operated on; 34 incision and drainage, 2 pneumonectomies, thoracoplasty 5, opening of superficial abscess 4, puncture and drainage 2; recoveries 26, recoveries with fistula 2, deaths 19.

OPINIONS OF WRITERS.

The following condensed opinions of various authors and operators have been collected:[12]

Jacobson.—Pneumonotomy and pneumonectomy for tubercular cavities have been attended with results so unsatisfactory that they can not be recommended unless possibly under very exceptional circumstances.

Koenig.—To perform such an operation the surgeon must ignore absolutely all his knowledge of pathology. (Peyrot.)

Keyes.—In tuberculosis the wide distribution of the lesions and general conditions forbid any operative interference.

Godlee.—Tubercular cavities should not be opened except in cases where the cough is harassing and the cavities single.

Bouchout.—Surgical treatment is contraindicated in tubercle.

Biondi.—Occasional cases of phthisis may be saved from death by operation.

Warren-Gould.—Pneumonotomy for tubercular cavities has not yielded favorable results, as the cavities are usually multiple. When the tuberculosis is advanced sufficiently to justify operation it is rarely limited to the apex only. In the early stage, which is the only time when total removal is possible, diagnosis is uncertain, and we can not expect, therefore, that the operation will be found applicable in many cases.

Powell.—Pneumonotomy offers but little hope, as the cavity is not often single.

Dandridge.—The fact that the removal of the local tubercular lesion does not necessarily relieve the system makes the operation uncertain in its benefits.

Yeo.—Temporary benefit is about all that can be expected.

Mosler.—Tubercular cavities should not be opened by the surgeon until an antiseptic is discovered which will destroy tubercle bacilli. Although the operation is possible, it should be employed only in exceptional cases.

Taufert.—Operation is inadvisable on account of the liability to hemorrhage, the dangers of pneumothorax and its uselessness.

Berliner.—Pneumonectomy is to be condemned.

Kocher.—Surgery in apical pulmonary tuberculosis is questionable because of the presence of tuberculosis in other parts of the lung.

Quincke.—Pneumonotomy is a dangerous operation.

Reclus.—Pneumonectomy for tuberculosis is to be condemned. If the disease is extensive the patient is too far gone, and if the disease is circumscribed medical measures are as good and much safer. Statistics are not wholly reliable, as recoveries are more likely to be published than deaths.

[12] From the original articles by Dr. Eugene Lindauer.

Ruggi.—Tuberculosis of the lungs is beyond the surgeon's interference.

Quenu.—Pulmonary surgery in tuberculosis is usually unsuccessful.

De Cerenville.—Operation dangerous. Five deaths in six cases.

Hahn.—Operation is unsatisfactory.

Porritt.—The treatment of tubercular lesions of the lung by drainage is an attempt to attain that which with few exceptions has thus far proved to be the unattainable.

Verneuil.—Operation is justified only in a few cases, where there is a single focus and the condition good. The abscess wall should be cauterized.

Hughes Bennett.—Operative interference in phthisical cavities has been a uniform failure.

Albert.—Results prove that pneumonotomy should not be done in tuberculosis and that pneumonectomy is never advisable in that disease.

Heitler.—Tubercular cases of any description are not operable by pneumonotomy or pneumonectomy.

Heydweiller.—Pneumonotomy is useless, since the disease is not cured by operation and the patient subsequently dies. Conclusions based upon forty-two cases, with twenty-three deaths, fifteen improvements and four relative cures.

Ricketts.—After operation in tubercular cases 60 per cent. recover. In 306 cases of pneumonotomy for various causes, tubercular and non-tubercular, 71 per cent. recovered, showing that surgery is beneficial.

Bull.—In rare cases of tuberculosis, where a large cavity is the predominating condition, the cavity may be laid open with a view to improvement of the patient and as a palliative.

Koch.—Pneumonotomy would be helpful in strictly localized tuberculosis of the lung, a condition which is of rare occurrence.

Krecke.—Operation is indicated when the cavity is single and there are symptoms of septic absorption.

Leser.—The excavation, especially if it is large, should be opened through the chest wall to permit purulent contents to escape. This operation should especially precede the use of Koch's tuberculin, since after tuberculin is used the discharge is too great to be removed by expectoration.

Wills.—Emphatically favors pneumonotomy in the early stages as good conservative surgery, saving life and giving comfort.

Garre.—Pneumonotomy is advisable in rare cases.

Kummel.—Operative interference is indicated when the cavity can be definitely located and stagnating conditions produce grave symptoms.

Richerolle.—Pneumonotomy in very large tubercular cavities is allowable, but not if they are numerous.

Rochelt.—Operation is justifiable if the symptoms are severe, or hemorrhage frequent, or the cavity is superficial. When the process is active and the temperature high, no operation.

Bloch.—Operation favorable in hemorrhage of the lung.

Sarfert.—Little encouragement for operation, yet is sometimes advisable, especially if the disease is circumscribed and the symptoms not severe.

Poirier and Jonnesco.—Have collected many cases. Favor operation, especially in the cases where the abscess forms in the lower lobe.

Fowler.[13]—Difficult to outline the exact cavity and to know when there are adhesions. The question of adhesion is a very important one as regards pneumothorax. If the disease is quiescent, operation not advisable; if the disease is advanced, it is useless.

Da Costa.—Operation is unjustifiable if the cavities are multiple and not circumscribed, or if the disease is progressing. Advise against pneumonectomy.

Sonnenburg.—Has abandoned the operation as useless, although one of his patients lived five years. Only those cases operable, where the disease is circumscribed, the cavity favorably located, the patient fairly strong and without hectic fever. The opening should be free.

Neve.—Successful case of drainage and application of creosote locally.

Manclaise.—Operation limited to circumscribed tuberculosis, without surrounding infiltration.

Salomoni.—Operation is of value in single cavities, but in spite of a few fortunate results is not to be commended except occasionally.

Tuffier.—Favorable to the operation, and yet he acknowledges that in only one case was he able to reach the focus at the time of the operation. Injections have proven themselves valueless. Pneumonotomy relieves symptoms if free drainage is secured.

Turban.—Operation advisable if one lung is healthy, even if the other is seriously diseased.

Murphy.—In advanced disease pneumonectomy is inadvisable, and in the early stage patients will not consent. Pneumonotomy gives a chance for free drainage and lessens the septic symptoms.

Wood.—Incision and drainage of a tubercular cavity is indicated when there is limited tubercular involvement and when the patient is suffering from the septic effects. These symptoms are ameliorated by pneumonotomy, and while a case is occasionally cured the majority die. Pneumonectomy is unjustifiable.

Ferguson.—Drainage and injection of iodoform give good results.

Ewald.—Operation is advisable.

Casini.—A circumscribed tubercular process may be attacked by surgical interference and the cavity treated with as much reason as one in a tubercular bone. A single cavity, even though it is deep, should be drained to prevent general infection.

Fabricant.—Pneumonotomy is advisable when the symptoms of infection from the cavity overshadow all others.

CONCLUSIONS AS TO HUMAN SURGERY.

1. With improvement in technic pneumonotomy will become a practicable operation, even in cavities at the apex. The operation would be especially helpful in the early period of cavity formation, but it is exceedingly difficult at this stage to obtain the consent of the patient, since hygienic and dietetic methods of treatment often result in cure.
2. In advanced cases, both tubercular and streptococcic infection are often present; the cavities are usually multiple and the operation can not cure. It may be employed, however, as a palliative to cough, hemoptysis and sepsis.
3. In abscess of the lower lobes, following pneumonia or pleurisy, whether tubercular or not, incision and drainage is to be recommended in any stage.
4. Pneumonectomy in our present stage of surgical and diagnostic skill is not advisable in tuberculosis.

---

[13] Trans. Amer. Surg. Asso., 1896.

5. With improved technic tubercular foci will in the future be eradicated, as we now eradicate tuberculosis in joints and other tissues. An efficient and certain method of producing strong adhesions between the two layers of the pleura at the site of the disease is the most important step in this technic.

6. The careful and methodical application of auscultation, percussion and the *x*-ray for the accurate locating of the diseased focus, is also an important factor in securing a safe operation.

7. Pneumothorax is so serious a menace to life that in all operations on the lung, an artificial respiration apparatus, like the Fell O'Dwyer or Matas instrument, should be at hand, together with a full jar of oxygen.

EXPERIMENTAL TECHNIC AND RESULTS.

For the primary induction of tuberculosis in the dog, injection with a long hypodermic syringe was made into the lung in the third interspace on the right side, one and one-quarter inches from the midsternal line, under thorough antiseptic precautions, and the results awaited.

The material used for infection was from 2½ to 3½ c.c. of a growth of tubercle bacilli, ground up in a sterile tube with sterilized water until in appearance and density the mixture was equal to a twenty-four-hour culture of typhoid. This made a white, thin, milky fluid, which flowed easily from the hypodermic.

For the secondary operation the animal was always given a full dose of morphia (one-quarter to one and one-half grains) an hour before etherization. The area operated on was first shaved, scrubbed with soap, then with alcohol, ether and bichlorid or turpentine and surrounded with sterile towels. Instruments and hands were thoroughly sterilized and all preparations made as in human operations.

The ether was administered by cone, as chloroform will kill, and a Fell O'Dwyer artificial respiration apparatus kept on hand, by the use of which life can be maintained in many cases where otherwise the animal will die. As the introduction of the tube through the mouth is too risky to the operator, it is better to open the larynx when necessity arises and insert the tube into the trachea, the inflation of the lung then being slowly and regularly maintained.

Silkworm suture; catgut drainage, or gauze; sterile gauze dressing; plaster of paris bandage. May dress with iodoform and collodion or with turpentine. In ligating lobe of lung, kangaroo tendon or chromicized catgut. Dogs were usually redressed on the second or third day, and, if clean, were allowed to go for several days. Whenever suppuration was found, dressed every two days, the wound being washed with bichlorid.

In some cases the dogs after injection of tubercle began to lose flesh at once, and in a month the loss was from two to four pounds; others developed a cough, but as the sanitary conditions in confinement and in the cellar were unfavorable, progress was, of course, naturally active. In spite of this several cases did not show any tubercular lesion even weeks after the injection. Many of the dogs showed foci of tuberculosis through the lobes of both lungs, the infiltration in many cases being as great in the opposite lobe as in the one injected. The mediastinal glands were usually found implicated. The lung tissue intermediate to the foci was usually normal. In a few cases the lower lobe was densely infiltrated with tubercular pneumonia. In none of the cases were the other organs affected nor the bones. One dog only died from tuberculosis (No. 3), living from September 2 to November 4. In three or four cases there was a localized abscess in the lung apparently not from the injection, but from the infection through the bronchi.

The dangers of the operation are illustrated by the fact that 4 died during the operation from pneumothorax; 2 others within thirty-six hours, one from hemorrhage into the bronchi from pleural suture, one from sepsis of lung abscess, from cutting off of blood supply of lung tissue by preliminary suture of pleura; 2 cases of pneumonectomy died of purulent pleurisy.

The dyspnea from pneumothorax during operation was always greatly relieved by grasping the lung and holding firmly in place. Incision into the lung of a dog, if sutured, will recover almost certainly, and also excision of a wedge-shaped piece. Puncture and incision of the lung recover. An entire lobe can be safely removed. A strong dog will probably survive removal of entire lung. Excision of diseased lung, of course, will not interfere so seriously with respiration as would the removal of a healthy lung. The lung should not be ligated en masse, but in small portions; the bronchus and its vessels should be ligated independently. The open end of the bronchus should be sutured.

DEDUCTIONS FROM EXPERIMENTS.

The production of adhesions is a most important part of the operative procedure. If these can be secured, either artificially or if they are present from the disease itself, the operation is not more serious than many major operations.

In the human being the position of the abscess can be much more definitely fixed than in the dog by auscultation, percussion and the *x*-ray. Operation, therefore, becomes one of greater certainty. If slight adhesions only are found, immediate stitching of the lung to the walls around the margin of the opening, while not avoiding pneumothorax, may escape pyothorax. If pneumothorax occurs, the most speedy method of relief is that of dragging the lung into the opening and fixing it, thus giving greater action to the opposite lung. Excision of the diseased area would be the best operation, provided the entire tuberculous portion could be definitely removed, a condition which at present does not seem possible. In dogs even a collapsed lung becomes functionally active in a few days after excision of a portion.

Experiment* 1.—Dog, 15 pounds. Injection 3 c.c. emulsion tubercle bacilli, right upper lobe, Aug. 26, 1901; ¾-grain morphia given previously. September 2 no ill effects; September 5 small abscess circumscribed at point of injection; September 20 loss of 1¾ pounds. Still losing flesh.

Operation.—Thirty-ninth day, one-half grain morphia given 20 minutes previous to etherization. Incision 2½ inches long, third interspace. With a long curved needle, silk ligature was carried through intercostal space, penetrating lung and brought out 1½ inches distant. Tied sufficiently firmly to bring visceral pleura in contact with parietal, intending to place similar one in fourth interspace and cross sutures at ends of these two, in shape of parallelogram to produce adhesions. Immediately after the passing of the first suture, however, bloody froth appeared at the mouth, respiration became difficult and in spite of the injection of 1/60 grain of strychnin and forced artificial respiration, the dog died quickly.

Postmortem.—Small coagulum in right pleural cavity; no other blood or fluid in pleura; no pneumothorax. Needle had evidently punctured a large pulmonary vein, and the bronchi were filled with blood. Air probably entered the veins from the perforated bronchi, as the heart was flabby and contained frothy blood, especially in the right auricle. Upper lobe entirely consolidated with tubercle; the two lower lobes normal, but the infiltrated lobe was yellow. Firm adhesions were present from the site of the injection to the apex, one and one-half inches wide; all other portions of lung free. Posterior mediastinal lymphatic glands enlarged to size of pigeon eggs; one anterior mediastinal gland also infiltrated. Abdominal organs healthy. One mesenteric gland enlarged.

---

* The experiments detailed were conducted at the Pepper Clinical Laboratory of the Hospital of the University of Pennsylvania, with the assistance of Drs. George M. Purves and Eugene Lindauer, without whose help they would have been impossible.

EXPERIMENT 2.—August 26. Dog. Weight 29 pounds. One and one-half grains morphia given; 3 c.c. emulsion tubercle bacilli injected into right upper lobe. Puncture sealed with gauze and collodion. September 27 loss of 7½ pounds. October 1, cough and expectoration; latter could not be obtained for microscopic examination.

Operation.—October 3. Morphia, ½-grain, 20 minutes before etherization. Fourth rib resected; accidental opening in the pleural cavity; adhesions were found slight; parallelogram suturing; pneumothorax was marked, but did not give extreme dyspnea. Death 36 hours later.

Postmortem.—Right lung entirely collapsed, 3 drams bloody serum in right pleural cavity. No large tubercular area of consolidation, but over entire pleura were numerous yellow foci, and in the upper lobe of the lung some yellow foci, which had not broken down. Anterior and posterior mediastinal glands enlarged, size of lima beans. Left lung partially collapsed, but upon the parietal pleura and the surface of the lobes of the left lung were nodules similar to those in the right. In the right lung there were no adhesions to the pleura at the site of the injections, but there were firm adhesions over the area of half an inch at the apex. No other adhesions in either right or left. Other organs healthy.

EXPERIMENT 3.—September 2. Injection 1½ inch to right of mid-sternal line, 3.5 c.c. emulsion tubercle bacilli. No cough, but progressive loss of weight, with weakness. Died November 4. Had cough and expectoration, but not enough to collect for microscopic examination.

Postmortem.—Markedly emaciated; right pleural cavity small amount of bloody serum; apex of right upper lobe consolidated with firm adhesions to ribs 1¼ inches in diameter; beneath these was a cavity in the lung substance an inch in diameter connected with the pleural cavity; space contained thin turebcular pus. In lobe of right lung, two similar tubercular consolidations; posterior mediastinal glands enlarged; anterior glands size English walnut; other organs healthy.

EXPERIMENT 4.—September 9. Weight, 34 pounds. Morphia 1¼ grains; injection of 3.5 c.c. tubercle bacilli emulsion. As there was no loss of weight, October 18 additional 3 c.c. injected in the same area.

Operation.—November 4; 3 inches of rib excised; area around point of injection sutured off in a parallelogram with silk carried through the substance of the lung, and sutures tied merely to bring surfaces in apposition. Dressed with sterile gauze, plaster of paris outside. Owing to an error, pneumonotomy was not done, as it should have been on the second day. Dog lost flesh and died November 29. Sinus at point of wound; right lung was strongly adherent as low as the third rib; the upper lobe condensed, but no positive tubercle foci; small abscess at the point of operation; glands not involved.

EXPERIMENT 5.—October 8. Weight 27 pounds; morphia, 1¼grains; injection 4 c.c. tubercle bacilli emulsion into right lung. November 2, dog greatly emaciated, scarcely able to stand.

Operation.—November 5. Lung sutured to wall as before. Wound made in pleura and dog died speedily, in spite of artificial respiration with Fell O'Dwyer apparatus; strychnin and digitalis.

Postmortem.—No adhesions nor effusion on either side. Both lungs evenly infiltrated with yellow tubercular nodules varying in size from a pin to that of a bean, a few of them breaking down in the center; no deposits in pleura nor in abdominal organs.

EXPERIMENT 6.—November 7, 18¾ pounds; 1 grain morphia given; ether; 2 in. incision over third rib. Visceral and parietal layers of pleura approximated by silk sutures, plaster of paris with the intention of producing adhesions before making the tuberculin injection. Next day 3 c.c. tubercle bacilli emulsion injected into the lung. November 29: dog has lost flesh rapidly.

Operation.—Previous incision healed by first intention except at lower angle where sinus persisted and through which much air entered; sinus leads into the lung through second interspace; acute pneumothorax followed the incision into pleura and dog died in five minutes.

Postmortem.—Right lung collapsed. Strong adhesions along lower margin of second to fourth rib, which could not be torn with moderate pressure of finger. The longitudinal sutures had evidently produced adhesions, but the transverse sutures had not, as they had been passed beneath rib from the second to third interspaces; lung not infiltrated.

EXPERIMENT 7.—November 12, 11 pounds, one-half grain morphia; ether; longitudinal sutures, first and second intercostal spaces 1¼ in., united by cross suture at ends around second rib; 2 c.c. emulsion of tubercle bacilli injected at end of operation.

Operation.—December 28. Incision through old scar, third rib resected subperiosteally. When pleura was opened acute pneumothorax developed, with great dyspnea; rapid tracheotomy performed; Fell O'Dwyer artificial respiration inflation practiced, with success in reviving; upper lobe of lung pulled into incision and sutured with catgut; projecting portion ligated with silk and cut off; wound closed with drainage; tracheal wound closed; sterilized gauze and plaster of paris bandage. Next day respiration 40; plaster stained with offensive discharge; lung slipped from its anchorage; collapse from the pneumothorax; drainage tube inserted; pleural cavity washed with boric acid solution.

Postmortem.—January 2. Right pleural cavity infected; yellow pus; adhesions at apex, but no consolidation in either lung; lung had slipped from anchorage; no evidences of hemorrhage; tracheotomy wound healed first intention.

EXPERIMENT 8.—December 12. Preliminary suturing of lung to chest wall with silk suture; 3 days later injection 3 c.c. tubercle bacilli emulsion; 11 days later, cough.

Operation.—January 24. Third rib resected subperiosteally 1½ in.; pleura was opened; breathing became labored, but not to an extreme degree. Tracheotomy done and artificial respiration apparatus used; dog revived. Adhesions were firm, but did not completely surround the line of incision. Lung pulled into opening and sutured to chest wall. Packed with sterile gauze. January 29, dog dressed. Air escaped from site of sutured lung.

Second Operation.—February 5. Second rib excised. When pleura was opened adhesions only partial, and pneumothorax followed; as the lung was adherent, symptoms were not serious; palpation of lung failed to find any consolidated area or cavity. Wound was packed, and a second injection of tubercle bacilli emulsion made into upper lobe. March 12: No apparent loss in weight, dog apparently normal.

Third Operation.—Lung exposed and palpated, but no cavity found, although incisions were made in one or two directions into the lung. Hemorrhage checked by packing with gauze. Died 24 hours after third operation.

Postmortem.—Upper lobe right lung adherent opposite second and third ribs; firm, anteriorly to the extent of 1½ in. Upper lobe shows mark of incision; pleural cavity contained much red clotted blood, but was otherwise normal; no tubercular infiltration in any portion of right or left lung; abdominal organs healthy.

EXPERIMENT 9.—December 12. Small dog. Pleural surfaces sutured as before; 2 c.c. tubercle bacilli emulsion injected in right upper lobe. January 15: no emaciation. Eating; drinking; lively.

EXPERIMENT 10.—Preliminary suturing of pleural surfaces. December 14, 3 c.c. tubercle bacilli emulsion injected.

Operation.—January 14. Preliminary incision made over trachea, not dividing rings. Incision, line of previous scar. Preliminary sutures of silk found. Fourth rib excised; adhesions around area firm; lung opened; penetration with grooved

TABLES (carefully prepared for me from the original publications by Dr. Eugene Lindauer).

No.	Reference.	Sex and Age.	Seat and Character of Disease.	Condition of Patient.	Adhesions.	Operations.	Immediate Results.	Final Results.	Autopsy.
1	Hastings & Storks: Lond. Med. Gaz., 1844-5, ii, 378.	Male, 38	Cavity left upper lobe; consolidation right upper lobe.	Very low; hemoptysis, emaciation, cachexia, etc.	Yes...	Pneumonotomy and drainage	Improved. . .	Discharged very much better

15	De Cérenville: Rev. Méd. de la Suisse, rom., 1885, v, 441.	Female, 15	Large cavity in left upper lobe.	Hectic fever; signs of a cavity.	No .	Resection second and third ribs; pleura sutured; four days later pleurotomy and pneumonotomy.	. . . . . .	Death on 16th day, due to pulmonary embolism and cachetic thrombosis.	Both lungs riddled with cavities; wound looked nice.
16	De Cérenville: Ibid .	Female, 25	Infiltration of upper left lobe with cavity	. . . . . .	Yes .	Pleura adherent; pleura and lung opened; cavity beneath clavicle.	No improvement . .	Death 6 weeks later; due to miliary tuberculosis.	Cavity began to cicatrize; miliary tubr. both lungs.
17	Neve: Lancet, 1887, i, 263.	Male.	Infiltration left apex; cavity in ant. surface up. r. lobe.	Symptoms of advanc'd tuberculosis.	Yes	Resection fourth rib; two small cavities opened with finger; drainage.	Improvement . . .	Discharged 4 wk.; no drain.; improv. contin. for months.	
18	Sézary et Vincent: Rev. de Méd., 1887, vii, p. 675.	Male, 22.	Cavity of lower right lobe; infiltration of right apex.	Typical symptoms of tubr.; cavity signs; no tubercle bacilli.	Yes .	Resection ninth rib; puncture with trocar; extensive opening; large cavity; drainage.	Very little improvement.	Death 9 days later . . .	Cavity base of tuberculous right lung opened; adhesions pleura and right lung. left apex tubercular.
19	Casini: Rivista Clin. e. Terap., 1887, No. 1.	Male, 40	Cavity on right side extending from third to fifth ribs.	Pain; fever; cough; hemoptysis; gradually much worse.	Yes	Resection fifth rib; cavity opened and cleansed with bichlorid sol. and iodoform.	General improvement; no fever after 15th day.	Progressive improvement . .	
20	Bruen: Proc Phila. Co. Med. Soc., 1887, viii, 203.	Male, 27	Infiltration upper left lobe; cavity in lower left lobe; slight infiltration of right apex.	Symptoms of advanced tuberculosis; signs of a cavity.	Yes .	Resection ninth rib on line angle of scapula; trocar; drainage; large cavity opened accidentally several days later.	General improvement	. . . .	
21	Cummins: Brit. Med. Jr., 1889, i, 194.	Male.	Cavity in lower lobe	. . . .	. . . .	Incision between seventh and eighth ribs; drainage.	. . . .	Great improvement	
22	Denison: Jour. Am. Med. Ass'n, 1890, i, 376.	Male, 26	Beginning consolidation in right lower lobe; cavity in left lower lobe.	Advanced cachexia .	.	Resection sixth and seventh ribs; cavity opened; vasolin and salol injected; drainage.	. . . .	Living 4 months later; very little cough and discharge; gaining weight.	
23	Tillmans: Brit. Med. Jr., 1890, i, 1363.	Male, 28	Leftsided empyema and tuberculosis of chestwall; advanced tuberculosis of left lung; pleura adherent to upper third.	Patient near death . .	Yes .	1st operation: Resection ribs, empyema. 2d oper: Removal of anterior chest wall between second and sixth ribs; left lung size man's fist; adherent; covered lung with pedunculated flap of skin from thorax; left open for local treatment; scraped left pleura. 3d operation: A month later transplanted skin to pleural cavity and changed it into a cutaneous cavity.	Lung shrank; spontaneous cure resulted.	Discharged cured 2 months later; living 2 years after operation, apparently well	
24	Spengler: Ver. der Gesellsch. deutscher Naturforscher u. Arzte, Bremen, 1890, ii, 237.	Female .	Large cavity in left upper lobe; tuberculosis of upper right and lower left lobes.	Advanc'd tuberculosis	No. .	Radical thoracoplasty; cavity not opened; collapse of wall of cavity follows operation; lung shrinks.	Gradual improvement	Seven months after operation patient presents neither cavity, nor tuberculous infiltration.	

25	Ledjard: Lancet, 1890, i, 964.	Male, 52.	Cavity in left upper lobe. .	Cough, expectoration, some emaciation.	. . .	Incision fifth interspace ant. axillary line; incision sixth rib; evacuation of pus; drainage.	No relief	Death on 4th day	Almost entire left lung is a cavity; right lung shows few tubercles.
26	Caselli: Raccoglitore Medic., 1891, xi, 235.	Male, 31.	Disseminated tuberculosis; cavity in right apex.	Signs of a cavity . . .	Yes .	Resection of second right rib; puncture; cavity opened and drained.	Improvement	Fifteen days after operation was improving.	
27	Krecke: Münch. Med. Woch., 1891, xxxviii, 399.	Male, 33.	Cavity in right lower lobe. .	Septic chills . .	Yes .	Costal resection; pleurotomy; pneumonotomy with dull pincette; cavity packed with iodoform gauze.	Improved; temperature normal; sitting.	Death from sudden hemorrhage.	
28	Kurtz: Wien. Medic Presse, 1891, xxxii, 1389.	Male, 30.	Cavity in left upper lobe. . .	Very low; cachexia . .	No. .	Incision second interspace; cavity opened with cautery; drainage; iodoform dusting.	Pneumothorax for 6 days; gradual improvement.	Well for three years; death due to acute diffuse tuberculosis of right lung.	
29	Hahn: Ver. d. deutschen Gesellsch. f. Chir., 1891, xx, 101.	. . . . .	. . . .	Good condition.	. . .	Pneumonotomy; drainage . . .	. . . .	Death about 3d week. . . .	General tuberculosis.
30	Hahn: Ibid	. . . .	. . . .	Good condition . . .	. .	Pneumonotomy; drainage	. . . .	Death 3 weeks after operati'n	Numerous cavities communicate with the one opened.
31	Hahn: Ibid	Fem., 22.	Cavity of left apex.	Signs of a cavity; expectoration fetid.	Yes .	Pneumonotomy; knife and cautery; iodoform packing; tuberculin was used; symptoms disappeared; cavity closed; symptoms returned; cavity reopened.	Improvement after both operations.	. . . .	
32	Leser: Münch. Med. Woch., 1891, xxxviii, 135.	Female, 42	Cavity of left upper lobe anteriorly and posteriorly; consolidation of rest of left lung.	Very weak; symptoms had existed for some years	Yes .	Removal first rib; pleurotomy; cavity punctured with trocar; opening enlarged with cautery; packing; used Koch's tuberculin	Gradual improvem't; tuberculin (locally & hypoderma ica'y) increases secretion.	Improvement.	
33	Leser: Ibid	Male, 42.	Small cavity of right apex. .	Symptoms existing for 3 years; typical.	Yes .	Operation as above.	Much improved . . .	. . . .	
34	Sonnenburg: Deutsch. Med. Woch., 1891, xvii, 21, and other places.	Male, 56.	General pulmonary tuberculosis; cavity of right apex; left lung little affected	Many tubercle bac.; signs of cavity; etc.	Yes .	Resection first rib; exploratory puncture; pneumonotomy opening of cavity; iodoform gauze.	Improvement; Koch's tuberculin was injected.	Cavity obliterated within 2 months; lived 5 years.	Old seat was cicatrized; new foci had formed.
35	Sonnenburg: Ibid. . . .	Male, 43.	Tuberculosis of both apices, cavity of left apex.	Advanced cachexia; signs of a cavity.	Yes .	Incision parallel with clavical puncture; pneumonotomy: cavity opened.	No improvement; Koch's tuberculin was injected.	. . . .	
36	Sonnenburg: Ibid	Male, 44.	Both apices affected, cavity left apex.	Disease existed 2 yrs.; symptoms of cavity.	Yes .	Puncture and pneumotomy; cavity opened.	No improvement. . . .	. . . .	
37	Sonnenburg: Ibid. . . .	Male, 35.	Tuberculosis of both lungs, cavity of right apex.	. . . .	No. .	Fourth rib resected; pleurotomy, partial pneumothorax, pneumonotomy.	No improvement; tuberculin was used.	Death during 7th week. . . .	
38	Roux: Rev. Méd. de la Suisse rom, 1892, xii, 567	. . . . .	Cavity in right upper lobe, posteriorly.	Signs of a cavity . .	No. .	Suture of pleura, pneumonotomy; small cavity opened with cautery; drainage 3 weeks later; principal cavity opened spontaneously.	Great improvement .	. . . .	
39	Roux: Ibid.	Female. .	Large cavity in lower lobe of right lung.	Signs of a cavity . . .	Yes .	Pneumonotomy, cavity opened with cautery; drainage.	Amelioration; drainage.	All signs of cavity disappeared.	
40	Lowson: Brit. Med. Jour., 1893, i, 1152.	Female, 34	Cavity of right apex, infiltration of upper right lobe.	Some emaciation; signs of a cavity.	. .	Resection 2d and 3d ribs; pneumothorax; collapse right lung; adh's upper lobe broken up, ligation of apex in two pieces, resection lung above ligatures, closure without drainage, pneumonectomy.	Barring a small localized empyemia, an uninterrupted recovery.	Discharged 10 weeks later almost well.	
41	Shurly: Jour. Am. Med. Asso., 1893, ii, 297.	Male, 48.	Cavities in l. u. lobe; balance consolid'ed; 1 cav. r. apex.	Very low	Yes .	Pneumonotomy; cavity very deep; drainage; chlorin gas injected.	. . . .	Death on 8th day from hemorrhage.	
42	Shurly: Ibid.	Male, 27.	Large cavity left apex; other cavities in same lung.	Very low	Yes .	Incision 3d intercostal space, cavity opened and drained, chlorin gas.	No improvement. . . .	Death on 24th day from exhaustion.	
43	Veje: Med. and Surg. Rep., 1893, ii, 1009.	Female, 28	Cavity in left lobe of lung, posteriorly.	. . . .	Yes .	Superficial incision, pus, gangrenous debris and gas.	Improvement. . .	Recovery	
44	White: Med. News, 1893, i, 38.	Female, 43	Cavity in lower right lobe. .	Typical symptoms . .	Yes .	Incision 6th intercostal space one inch front of axillary line; cavity drained; second operation one in. posterior to axillary line.	Improvement	. . . .	
45	Dandridge: Ann. of Sur., 1894, vol. xix, p. 129.	Male, 29	Cavity of right lower lobe infiltration of right apex. ,	Physical signs of a cavity.	Yes .	Resection eighth and ninth ribs, axillary line; evacuation of pus, debris and caseous material; boracic douche; drainage.	Improveme't follow'd by removal of drain; incision healed.	Respiratory sounds heard at much lower level than before; area of dulness diminished; general improvem't.	
46	Poirier: Bull. et Mem. d. l. Soc. de Chir. de Par., 1894, xx, 630.	. . . . .	Abscess of lung communicating with cavities in a tuberculous subject.	. . . .	. . .	Pneumonotomy and drainage.	. . . .	Recovery	
47	Doyen: Semaine Med., 1895, vol. xv, p. 419.	. . . . .	Large tubercular cavity . . .	Signs of a cavity . . .	. . .	Pneumonotomy; drainage.	. . . .	Death during same night . .	
48	Doyen: Ibid.	. . . . .	Tuberculosis	. . . .	. . .	Incision, pneumonectomy; piece size of an orange removed.	. . . .	Recovery	
49	Michaux: Ibid., 418. . .	Female, 20	Multiple cavities of right lung, especially lower lobe.	Long standing series of symp.; signs of a cavity.	Yes .	Resection of seventh and eighth ribs; pleurotomy; multiple punctures, lung cautery, drainage.	. . . .	Death three weeks later. . .	Numerous cavities; purulent bronchiectasis.
50	Michaux: Ibid.	Female, 25	Tubercular cavity	Signs of a cavity . . .	Yes .	Similar operation; eighth and ninth ribs removed; cavity not found.	. . . .	Death four weeks later, due to extension of disease.	Cavity in lower lobe; disseminated tuberculosis.
51	Salomoni: Clin. Chirurgica Milano, 1895, p. 65.	Male, 34	Tuberculosis of left lung. .	Symp of mixed infec.; no signs of a cavity.	Yes .	Fifth, sixth, seventh, eighth and ninth ribs resect.; pneumonotomy	. . . .	Much improved three months later.	
52	Tuffier: Sem. Med., 1895, p. 417.	Male, 25.	Tuberculosis localized to right apex.	Tubercle bacilli found in sputum.	No .	Suturing two layers of pleura to prevent pneumothorax; excision of apex with 2 cm. of healthy lung; wound closed without drainage.	Discharged cured on ninth day.	Living 4½ years after operation.	

No.	Reference.	Sex and Age.	Seat and Character of Diseases.	Condition of Patient.	Adhesions.	Operations.	Immediate Results	Final Results.	Autopsy.
53	Quincke: Mitteil aus den Grenzgeb. der Med. u. Chir., 1896, vol. i, p. 234.	Male, 46.	Cavity of right upper lobe...	Symptoms of advanced pul. tuberculosis; signs of a cavity.	No. .	Application of zinc chlorid to produce adhesion; 8 da. later cautery; no cavity found: 8 days later enlargement of wound; removal of 1st rib; cautery; no cavity found; week later removal of second rib; cavity opened.	Improvement of patient.	Death three years later . . .	Cheesy tuberculosis of both lungs in right upper lobe; several cavities.
54	Bier: Cited by Quincke, Ibid.	Male, 23.	Large cavity in right apex ..	Signs of a cavity . . .	Yes .	Subperiosteal resection; second and third ribs; a year later resection of second rib, cavity opened; cautery; resection, third, fourth, fifth and sixth ribs; drainage.	Retraction of chest wall during next few wk.; symp. dimin.; general emphysema at once.	Death 28 hours after second operation.	Right lung adherent to chest wall; upper lobe contains shrunken cavity; another cavity, egg size, middle and lower lobe full of tubercles; left apex has a scar; numerous tubercles throughout left lung.
55	Franke: Ibid, p. 688 . .	Female, 24	Cavity in right upper lobe..	Signs of cavity; sputum cont. tubr. bac.	Yes .	Resection of second rib: cautery; tamp. of iodoform gauze in cavity.	Great improvement .	Death 17 mos. later. influenza; fistula only 1½ cm deep.	
56	Bozzolo: Gazz. degli Ospedali, July 1, 1898.	Male, 36.	Cavity in right lung	All the symp. of tubr, but no tubr. bac.	1 No 2 Yes	Pneumonotomy followed by syncope; 2 months later again incised; 2 cavities drained.	. . . .	Recovery	
57	Tait and Abrams: Med. News, 1898, p. 263.	Male, 7.	Acute tuberculosis cavity in left lower lobe; later, signs of cavity in right apex.	. . . .	Yes .	Pneumonotomy and drainage; 1 yr. later resection of second, third, fourth and fifth ribs; pnemonotomy; drainage.	Great improvement after first operat'n; remained well 1 yr.	Death 28 hours after second operation	
58	Malbot: Arch. provin de Chir., 1898, No. 12, 1899, Nos. 1 and 2.	Male, 29.	Cavity in left upper lobe; tuberculosis of right lung.	Symptoms of cavity; symp. of advanced tuberculosis.	Yes .	Cavity opened and drained; water, potass., permang., tinct. Cl_2 sol. 1:15 for cleansing and cauterizing.	General improvement	Wound closed in 3 months' time; apparent recovery.	
59	Mayo: Northw. Lancet, 1898, xviii, 441.	Female, 38	Cavity of left lower lobe . . .	Signs of a cavity .	Yes.	Incision at posterior, anterior and axillary line; cavity opened and drained for 3 wk.; 3 ribs resected.	Great improvement at first.	Death after 5 months, from spread of disease.	
60	Karewsky: Vertrage d. deutschen Ges. f. Chir., 1898, xxvii, pt. 2, 285.	Female, 30	Cavity in lower left lobe; pleurisy.	Signs of a cavity; hectic fever, etc.	Yes . .	Resection of eighth, ninth, tenth and eleventh ribs: cavity ruptured into pleural cavity; cheesy material curetted from pleura and lung cavity; drainage; curettement several months later.	Improvement for several months.	Since second operation disappearance of all symptoms.	
61	Salomoni: Cong. of Ital. Surg., Oct., 1898.	Male, 22	Cavity in lower lobe of left lung; empyema.	Tubercle bacilli in discharge from empyema fistulæ.	Yes .	Resection of ribs (6th-11th); pleura opened with cautery; 2 cavities in lung below; purulent collection; curettement; drainage.	Improved quickly . .	18 months later condition fair; right lung good; one fistula remains over left lung.	
62	Strapesko: Ann. of Russian Surg., 1899.	Female, 25	Tubr. cavity had opened externally; it appeared to be caries of ribs.	. . . .	. . .	Cavity opened; curetted with spoon; tamponed.	Improved..	Healed soon.	
63	Strapesko: Ibid.	Male, 36	As above	. . . .	. . .	Identical procedure	Improved.	Healed soon	
64	Turban: Berl. Kl. Woch., 1899, xxxvi, 458.	Male, 21.	Infiltration of right upper lobe; almost entire left lung is one cavity.	Typical symptoms and signs.	Yes .	Removal of portions of fourth to seventh ribs; closure of wound; primary union; wound reopened after 2 mo.; resection of portion of sixth to ninth ribs; destruction of periosteum; lung c. much smaller.	Prim. incre.; second. decre. of symp., with consid'ble shrinki'g of lung; terti. incr.; consid'ble improvement of symptoms.	Three years after second operation alive; condition no worse than after operation.	
65	Tuffier: Bull. et Mem d. l. Soc. d. Chir. d. Paris, 1900, xxvi. 342.	Female, 30	Pulmonary gangrene; sputum contains tubercle bacilli.	. . . .	. . .	Incision; pneumonotomy; 8 cm of lung resected; drainage.	. . . .	Perfect recovery after six months; fistula persists: no tub. bac.	
66	Ferguson: Med. News, 1900, i, 405.	Male, 27.	Abscess beneath pectoralis major secondary to tuberculosis of lungs and tubercular osteitis.	Good; no signs of cavity.	. . .	Three operations. 1, Opening of abscess; drainage. 2, Resection third and fifth ribs; packing with iodoform gauze 3, Resection of a piece of tuberculous lung; packing with iodoform powder twice a week for month.	No improvement after first two operations; remarkable improvement after the third.	Apparently cured.	
67	Sarfort: Deutsche Med. Woch., 1901, p. 103.	Female, 40	Large cavity in right upper lobe.	Fever; hemoptysis; cachexia; signs of a cavity.	Yes .	Resection of second rib; pleurotomy; pneumonotomy; cavity opened extensively.	Improvement; fever & hemoptysis ceased; cavity contracted.	Death 5 mo after operation, due to an intercurrent pneumonia.	Right apex a thick cicatricial mass; few tubercles scattered through lung; no other cavity; left lower lobe hepatized.
68	Wills: Jour. Am. Med Ass'n, 1901, i, 19.	Male, 45.	Cavity in lower lobe of left lung; consolidation of left apex.	Typical symptoms of 3d stage of disease	Yes . .	Resection sixth rib; pleurotomy; drainage; operation not continued because of man's bad condition. Nine days later spontaneous rupture of cavity into wound.	Gradual improvement	21 months later no cavity; had gained 75 pounds; apparently well.	
69	Wills: Ibid	Male, 30	Cavity in lower lobe of right lung; infiltration of both apices.	As above	Yes . .	Resection of portions of eighth and ninth ribs in front of their angles; pleurotomy; drainage. Six days later pneumonotomy; drainage; irrigation with formalin.	Improvement.	Died 6 months later	
70	Maffert: Quoted by Murphy, Journal A. M. A., 1898, ii.	Male, 19.	Chondro-sterno-costal tuberculosis and tuberculosis of lower lobe of left lung.	Symptoms of purulent pleurisy; no sign of a cavity.	. . .	Resection sixth rib in axillary line; discharge of pus containing bacilli; lavage; drainage.	. . . .	Death 1 month later	Enormous sterno-costal cold abscess, communicating with a cavity opened by a narrow orifice; right lung almost completely destroyed; left studded with tubercles.
71	Porritt: Lancet, 1892, vol. ii, p. 1318.	Male, 65	Cavity right upper lobe . . .	. . . .	. . .	Second and third ribs removed; anterior and posterior.	Improvement.	Death 3 years later.	
72	Porritt; Ibid	Female, 15	Cavity left upper lobe	. . . .	. . .	First, second, third and fourth ribs removed; posteriorly.	. . . .	Death second day	
73	Porritt: Ibid	Male, 47.	Cavity left upper lobe.. . . .	. . . .	Yes. .	Second, third and fourth ribs removed; anterior to axilla.	. . . .	Death pneumonia, within few day.	

director; small amount of pus evacuated, but in spite of completed tracheotomy and the use of Fell O'Dwyer artificial respiration apparatus, dog died.

Postmortem.—Many adhesions beneath the second and fifth ribs, but no area of consolidation and no nodules were found in either lung. The upper lobe of the sutured lung was very friable, and broke down readily under the fingers, a condition that had been discovered before death, probably due to the cutting off the blood supply by the sutures.

EXPERIMENT 11.—March 18. Preliminary exposure of trachea, but tube not opened. Third rib excised. Acute pneumothorax as soon as the pleura was opened, but symptoms not severe. Lung seized with forceps and pulled into the opening; improvement in symptoms; lung anchored to margin of wounds by interrupted silk sutures; lung ligated, and portion removed; stump sutured to chest wall.

EXPERIMENT 12.—April 4. Two injections previously of 2.5 c.c. tubercle bacilli emulsion. Has not lost weight. Excision of one inch third rib. Upper lobe seized as quickly as possible and dragged into the wound through chest wall. Dyspnea was immediately greatly lessened. Artificial respiration other than manual not required. Lung sutured to margin of wound, ligated with silk and cut away. Drainage with gauze. April 24, apparently perfectly healthy and eating and drinking normally. Killed by chloroform. Small narrow sinus presented leading to third rib; strong adhesions at site of suturing, 1 in. in each direction; small area of infiltration ½ in. in diameter adjacent to site of suturing. Consolidated, carnified and sinking in water. Remaining portion of lung had regained its function, was crepitant and floated. Few adhesions in left pleural cavity. Abdominal and other organs healthy.

EXPERIMENT 13.—April 5; ½-grain morphia, hypodermic ether. Preliminary incision over trachea without opening the tube. Subperiosteal excision third rib. On opening pleura, pneumothorax and dyspnea severe, but as soon as lobe of right lung was grasped and dragged forcibly into the wound, improvement occurred. Artificial respiration not required. Lung sutured to chest wall with silk sutures tight, so as to prevent all air from entering pleural cavity; lung ligated and cut off. Incision in throat closed. Wound drained; sterile gauze; plaster of paris. April 24, killed with chloroform. Small sinus leading to silk suture. Right pleural cavity strong adhesions 1 in. from point of suturing; lower and posterior parts of upper lobe normal in color and appearance; crepitating on pressure and floating in water; right lower lobe normal; in the area of excision there was consolidation; was non-crepitant; remainder of upper lobe had evidently regained its function.

EXPERIMENT 14.—Trachea exposed. Third rib excised; acute pneumothorax with dyspnea relieved by dragging lung into the opening and holding it with hemostatic forceps. Trachea incised and artificial respiration kept up with bellows, but death occurred in about a minute and a half after pleura had been opened.

EXPERIMENT 15.—Pneumonectomy; suturing of lung. Small dog. Incision in left side between fifth and sixth ribs; marked collapse when pleural cavity opened; ether then suspended; lower lobe caught with blunt forceps, pulled into the opening and sutured to the wall with chromicized gut. Muscle sutured with silk; dressed with collodion; dyspnea great, but dog walked in ten minutes and the following day had apparently suffered nothing from the wound. Ninth day, superficial stitches gave way and the wound opened; adhesions to the wall seemed firm and strong; incision was made into lung substance one-third inch deep; hemorrhage controlled by packing; drainage. Dog killed at end of 4 weeks; wound entirely healed; had not lost his appetite since second day; firm adhesions to the wall; pleura smooth and healthy; effusion.

EXPERIMENT 16.—After laying bare the intercostal muscles chromicized catgut suture carried with curved needle through the lung and was drawn firmly against the parietal pleura. Tenth day pneumonotomy. Adhesions seemed firm, but by an accident loosened at one side, the pleura became infected, causing the death of the dog in two days. Pleura contained a large amount of fetid pus and the lung had collapsed.

EXPERIMENT 17.—Incision fifth interspace. Endeavor made to produce adhesions of the pleura by Paquelin cautery; failure. Dog killed with chloroform on the following day.

EXPERIMENT 18.—Ether. Opening seventh interspace, lung turned into the wound. Anchored, ligated and cut away. Dog killed 35 days later. Soft parts entirely healed. Lung firmly adherent to thoracic wall at point of suture, otherwise restoration of function good.

SUMMARY OF TABLES.

Pneumonotomy of apex 34; recoveries 20 (of whom 2 died in from 3 months to 3 years later); deaths, 14; operative recoveries 59 per cent. Lower lobes 20; recoveries 15 (of whom 2 died within 15 months); speedy deaths, 5; operative recoveries, 75 per cent. Location of cavity not mentioned, 7; recoveries, 4; deaths, 3; operative recoveries, 57 per cent. Total pneumonotomies 61; recoveries, 39; deaths, speedy, 22; deaths later, 10; operative recoveries 64 per cent.

Pneumonectomies, 6; recoveries, 4; operative recoveries, 67 per cent. (Nos. 10, 11, 40, 48, 52, 66. See tables).

Excision of ribs to produce collapse of chest and lung, 8 operations on 7 cases; recoveries 5 (one died 3 years later); deaths, 3; operative recoveries, 63 per cent. (Although the cases are few, yet the percentage of recoveries is no better than when lung was entered.)

Total operations for tubercular cavities 75, upon 73 cases, with 64 per cent. of operative recoveries. It is impossible to secure the final result in these cases, and even if secured, it would be difficult for faithful comparison to set aside 73 cases of precisely equal severity; moreover, the results that would have been obtained from medical treatment in these 73 cases can be only conjectured. The presumption is that they were of serious type, otherwise they would not have been subjected to operation, consequently the ultimate death rate would have been very high under any form of treatment.

CONCERNING THE SYMPTOMATOLOGY AND ETIOLOGY OF CERTAIN TYPES OF UVEITIS.[*]

G. E. DE SCHWEINITZ, A.M., M.D.
PHILADELPHIA.

In ophthalmic practice three disease manifestations are encountered to which the name "keratitis punctata" has been applied. Two of these are affections of the cornea, the third is not; that is to say, the primary lesion is not corneal. They are as follows: (a) *keratitis superficialis punctata,* in which, in general terms, numerous small punctiform or linear spots appear below Bowman's membrane, the overlying cornea being slightly hazy and the epithelium a little elevated; (b) *keratitis punctata vera* or *syphilitica* of Mauthner, in which circumscribed pinhead-sized, grayish spots appear in the parenchyma of the cornea, and, moreover, in its various layers; the iris is not involved. Constitutional syphilis is the etiologic factor. To distinguish it from the preceding manifestations Fuchs suggests the name "keratitis punctata profunda." (c) *Keratitis punctata,* in which a notable manifestation consists of a precipitate of opaque dots on the posterior elastic lamina of the cornea, generally arranged in a triangular manner, with apex pointing upward, and which from the beginning may be or may not be associated with the signs of iritis.

To this last-named condition the older writers gave the names "aquo-capsulitis" and "hydro-meningitis," because it was believed that it represented a disease depending on an inflammation of a hyaloid membrane, which was supposed to line the anterior and posterior chambers as a serous sac and which was connected with the hyaloid of the vitreous.

With the belief that the disease depended on a specific participation of the membrane of Descemet in its lesions, arose the name "descemetitis," which is still commonly employed.

To those cases in which this punctate deposit on the posterior lamina of the cornea is associated with an iritis, without great tendency to form synechiæ, with a deep anterior chamber and with a disposition to increased intraocular tension, the name "serous iritis" has been and is still commonly given, but, as De Wecker very forcibly objects, the inflammatory product of a serous iritis is not of a serous nature, but is essentially cellular. The iris suffers secondarily from this cellular infiltration which is communicated to all the neighboring parts, the sclerotic, the cornea and the choroid. The points of departure of this cellular inundation are the lymphatic spaces of the eye, and he contends, therefore, that a serous iritis represents a lymphangitis anterior of the eye, having its principal situation in the pericorneal lymph spaces.

Long ago Von Arlt noted that in a certain number of eyes with punctate deposits on the cornea inflammatory changes in the iris are practically absent and the pupil dilates readily. These cases he attributed entirely to cyclitis. The cyclitic origin of the disease has been strongly maintained by E. Treacher Collins, especially after his discovery of the glands of the ciliary body, his belief being that the so-called serous iritis is primarily a catarrhal inflammation of these glands. The secretion of these glands, he maintains, becomes augmented, causing increase in the aqueous humor and deepening of the anterior chamber. The aqueous becomes altered in character, contains leucocytes, pigment cells and fibrin, and these formed elements gravitate and are deposited on the lower portion of the posterior face of the cornea. Therefore, it has been suggested that the disease should be named "serous cyclitis," or "iridocyclitis."

It has, however, been noticed by many that when the characteristic punctate deposits appear upon the posterior surface of the cornea, if the media are sufficiently clear, recent patches of choroiditis can often, perhaps always, be found in some portion of the fundus. Particularly good studies of this association have been made in England, beginning, I think, with Hill Griffith's observations more than fifteen years ago. He believed that the dots on Descemet's membrane were formed in the choroid, set free in the vitreous and carried by the nutrient currents of the eye to be deposited on the back of the cornea. His view necessitated the admission that the suspensory ligament was permeable to solid particles. The choroidal origin of so-called descemetitis, however, is much older than this. For example, Von Graefe himself described in 1856 the association of choroidal lesions with this condition, and we find Schweigger stating that inasmuch as the ligamentum pectinatum sinks into the anterior part of the ciliary body, it may be easily understood how the epithelium upon the membrane of Descemet may become affected by an extension of disease from the choroid without any participation by the iris, and he goes on to describe a case in point, the choroidal disease having been situated in the macular region. I mention these facts because quite recently a good deal has been written on this subject as if the association of this condition with choroidal disease was a new discovery.

It is well known that not only in so-called serous iritis, but in all varieties of iritis, corneal lesions are always demonstrable by careful examination with a suitable corneal loup in the form of infiltrations in the substantia propria, dot-like deposits on Descemet's membrane, and striations in the posterior corneal layers. These have been well described and classified by Dr. H. Friedenwald. There is, however, one fairly constant clinical picture, which is, in a sense, characteristic, to which the names previously recited, all of which are more or less inexact and misleading, have been applied, viz., a deposit of variously-sized and colored dots, arranged usually in a triangular manner on the posterior layer of the cornea; an anterior chamber, sometimes deep and sometimes of ordinary depth; generally, but not constantly, iritis and cyclitis; hyalitis, and practically always some form of choroiditis, the last-named conditions being the primary lesions in most of the cases. In perfect examples there is reason to believe that the entire uveal tract is more or less involved, and hence the name uveitis is appropriate.

In general terms, the causes of uveitis may be diathetic, toxic or infectious. Thus we have causes depending on certain constitutional diseases, for example, rheumatism, gout and diabetes; on specific infectious diseases, for example, influenza, syphilis, gonorrhea, tuberculosis and scrofula, that is, tuberculosis of the lymph glands, and specific fevers; on diseases of the blood, for example, anemia; on anomalies of the urinary secretion, for example, lithemia; on local diseases, for example, of the pelvic region and of the rhinopharynx. In what manner these various ailments and conditions cause iridocyclitis, or, to use the more comprehensive term, uveitis, has not been carefully determined. But it does not seem to be unreasonable to assume that it represents an effort on the part of the uveal tract to expel from its tissues some toxin, bacterial or otherwise, precisely as we know that certain forms of dermatitis originate in an effort of the skin to eliminate a poisonous agent. Such an explanation is not a new one. Sydney Stephenson has maintained that inasmuch as many inflammatory affections of the iris and ciliary body are due to microbic infection, there exist good grounds for believing the proximate cause of all cases of endogenous iridocyclitis to be the excretion by the ciliary body of micro-organisms or their products. This excretory effort need not be limited to the ciliary body, but may include the choroid. A significant fact in this connection is the well-known favorable action of pilocarpin in affections of the ciliary body and choroid. Their excretory efforts are increased under the influence of this drug, and hence its curative power. We may say that the uveal tract sweats exactly as does the skin. Time does not permit me to elaborate these suggestions further, or to go more deeply into the etiology of uveitis. I wish now to present for consideration certain clinical types of this affection with illustrative cases.

1. RECURRING AND MALIGNANT UVEITIS TERMINATING IN SECONDARY GLAUCOMA AND CATARACT.

The following cases illustrate this type of the affection and indicate that although the termination in each may be similar, the earliest stages, and in some respects the course of the disease, are not identical.

Case 1.—A. H. R., aged 35, male, born in Pennsylvania, married, lawyer, consulted me Jan. 16, 1899.

History.—With the exception of the ordinary illnesses of childhood, the patient has always been healthy. He denies venereal disease of any kind and his habits have always been good. His father is alive and a well-preserved man, having no trouble except cataracts. His mother and one aunt died of phthisis. The patient had attacks of inflammation in his right eye when he was a child and has had enlarged lymph glands. Indeed, it is probable that both eyes suffered from attacks of choroiditis in childhood. About ten years before the date of his visit to my office, he consulted an oculist who writes as follows: "The patient came to me about ten years ago with an attack of choroiditis and vitreous opacities of the right eye. The choroid showed the marks of previous attacks in both eyes. Since that time he has had numerous attacks of fresh choroiditis," but apparently no serious involvement of the iris was present in these attacks, at least none is described. The iris became involved three months prior to this examination, i.e., in November, 1898.

Examination.—The patient is a hearty, healthy-looking man, giving no evidence of any constitutional disease.

Eyes.—V. of R. E., fingers at 50 cm. There was marked iridocyclitis with much thickening of the iris, the pupil being semi-dilated, and intense punctate keratitis. A dim red reflex could be obtained from the fundus when the eye was turned up and in, and large black masses could be detected in the vitreous. When the eye was turned down and out, a large elevation was evident of a purplish or of a somewhat violaceous tint, that is to say, a scleral staphyloma. T. was +1. The field was contracted in the manner shown in the diagram (Fig. 1).

V. of L. E. 6/50. The media were clear, the disc of fairly good color; no serious change in the retinal circulation. The entire macular area was occupied by a large expanse of atrophic retino-choroiditis, with patches of atrophy, pigment-heaping and yellow exudate. Under the usual treatment of sweats, mercury, iodids, galvanism and massage, the right eye gradually quieted, that is to say, the marked irido-cyclitis disappeared, but the lens became entirely cataractous and the punctate keratitis changed to a dense infiltration in the lower portion of the cornea. The left eye has continued unchanged and has never shown any signs of punctate keratitis.

Case 2.—C. L. S., aged 23, female, single, born in Pennsylvania, consulted me first May 20, 1895.

History.—When a child the patient in rapid succession had measles, scarlet fever and smallpox. For a year afterwards her eyes were subject to inflammation. At 12 she had malaria, and at 16 an attack of "redness in the face" which looked like erysipelas. She has suffered much from menstrual disturbance. The family history is good, parents and brothers and sisters being healthy. In February, 1894, the patient was the subject of an illness, which was characterized by chills, intense headache and general fever lasting about a week. It is probable that this was some form of influenza. Soon afterward the vision of the left eye, which, however, had always been a weak eye since it was ulcerated in early childhood, began to fail. Preceding the failure of vision, black spots were much in evidence. Similar failure of vision, but not preceded by any general illness, began in right eye ten months later.

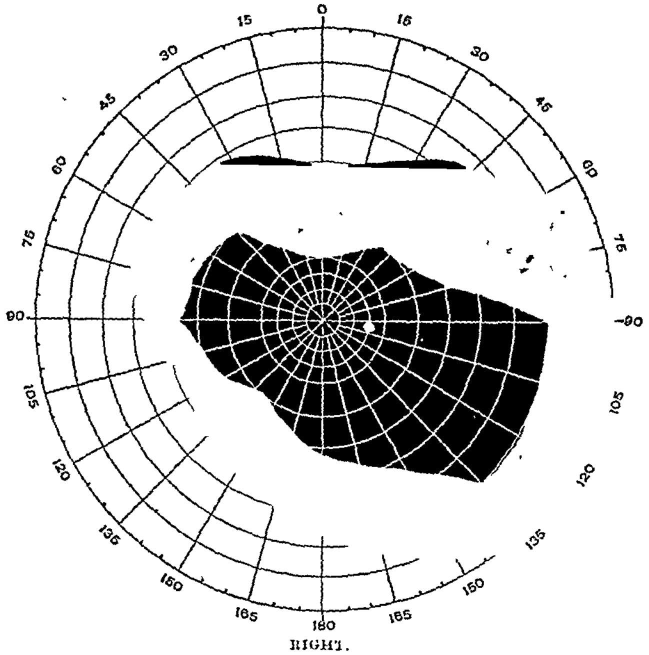

Fig. 1.—Case 1. Visual field, right eye. *Malignant uveitis in stage of secondary glaucoma.*

Examination.—The patient is a moderately tall brunette, with pallid skin. General examination failed to reveal any lesion of the internal organs. A pelvic examination was not made. The urine was normal and the blood examination was as follows: Hemoglobin 65 per cent.; red blood corpuscles 4,310,000; leucocytes 10,400. The differential count of the leucocytes was as follows; Neutrophilic polymorphous leucocytes 83.5 per cent.; oxyphilic polymorphous leucocytes 1 per cent.; mononuclear and transitional leucocytes 5 per cent.; lymphocytes 10.8 per cent.

Eyes.—V. of R. E. 6/30; pupil semi-dilated (under the influence of atropin); pigment spots on the capsule of the lens showing the position of former synechiæ. On the posterior surface of the cornea many large dots of gray-white color, somewhat irregularly placed (Fig. 2). The fundus was dimly seen, owing to some opacity in the vitreous. The disc was oval, much congested, and its margins distinctly veiled; the veins were large and tortuous, the arteries about normal in size and the fundus generally edematous.

V. of L. E. fingers at 2 feet; marked punctate keratitis and some striæ in the lens, but cornea and deeper media too hazy to permit any study of the fundus.

Re-examination.—The patient was not seen after this first examination for nearly a year, when she returned with the statement that her eyes had been worse for the past month. Examination now showed unusually large deposits on the posterior surface of each cornea, which could be well studied on the right side (Fig. 3). These dots were gray-white in color and fully a mm. in diameter, the intervening cornea being slightly hazy. Vision was reduced in the right eye to counting fingers at one foot and in the left eye to shadows; no fundus-view on either side.

Treatment.—Under the most vigorous treatment, consisting of sweats, leeching, iodid of potassium, and inunctions of mercury continuing for a year, the vision finally rose in the right eye, with proper correcting glass, to 6/12 and part of 6/9, and in the left eye to 6/60. The spots on the cornea almost disappeared, although a few very fine ones could always be noted in the more dependent portions. During this year there were several attacks which yielded to increased vigor of treatment, one of them being associated with or preceded by a marked gastralgia which lasted for nearly six weeks.

Again the patient was not seen for a year, when she returned with the statement that the vision last recorded had obtained until four weeks prior to her visit, when it began to fail. It was now in the right eye 4/60 and in the left eye 3/100, and the very large spots which had previously been noted were again manifest. For a few months the patient attended irregularly to treatment and then disappeared for a year. At the end of that time, during which she had had numerous attacks, particularly in the spring and summer, associated with severe la grippe, vision was greatly disturbed, being in the right eye about 1/100 and in the left eye fingers at 50 cm. The irides of both eyes were thickened, completely attached to the capsule of the lens and the pupillary spaces occluded with thick membrane. The spots had consolidated, as it were, into an area of thick infiltration at the bottom of each cornea. T. + 1 and the visual fields indicated that secondary glaucomatous conditions were established (Fig. 4).

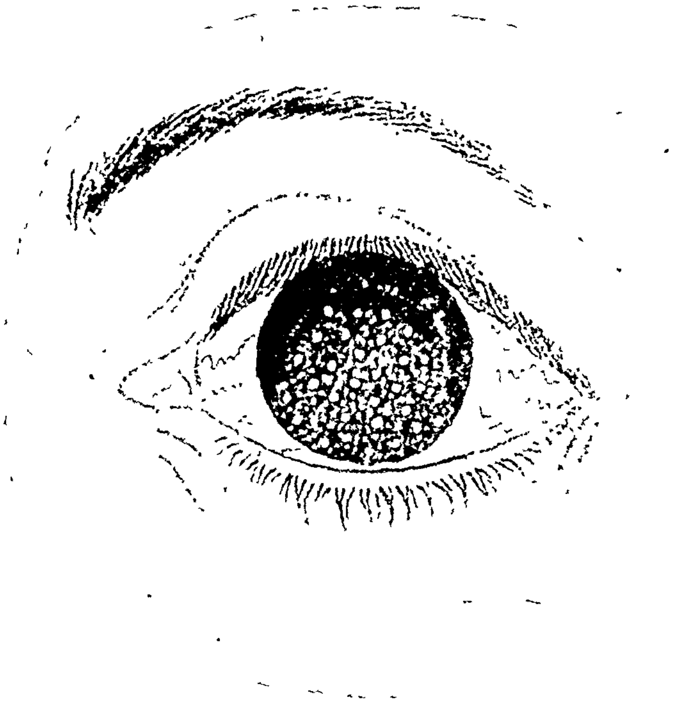

Fig. 2.—Case 2. Malignant uveitis. Early stage. Large dots irregularly placed.

Operation.—No improvement took place under the ordinary treatment, and on April 19, 1899, iridectomy was performed on the right eye, revealing a partially cataractous lens. Vision improved to the ability to see Sn. 60 at 1 meter. Somewhat later, iridectomy was performed on the left eye, but the coloboma almost immediately closed during an attack which shortly followed the operation. Gradually the cataract thickened and became complete about a year after the iridectomy. The patient then drifted into other hands. The cataract was removed, but without materially improving vision. When last examined, in the right eye the coloboma was filled with the remains of cortex and thick lymph, the lower half of the cornea was densely infiltrated; in the left eye, up and out, there was some clear cornea, but elsewhere it was densely infiltrated (Fig. 5).

Case 3.—S. S., aged 20, born in Maryland, single woman, consulted me first April 30, 1898.

History.—There is nothing special in the patient's history, at least in her early history, which throws light on her present condition, and she has not suffered from any severe illness. Both parents are well, two older brothers and sisters and two younger are in good health. One brother, however, has had phthisis. In January, 1898, the right eye became inflamed while the patient was studying at college, which was attributed to hard work and exposure to the bright light from the snow. Gradually the eye got worse, in spite of active and vigorous treatment at the hands of a competent oculist.

Examination.—The patient was a small, slender woman, although with the exception of anemia of the chlorotic type, as evidenced by the blood count, physical examination failed to reveal organic disease. The blood examination was as follows: Color fairly good; coagulation normal; hemoglobin 65 per cent.; red blood corpuscles 4,282,000; leucocytes 11,000; no poikilocytosis. The chest was emphysematous in type, but the respiration was deep and full and the lungs normal in all respects. The cardiac action was rapid and regular and all the sounds clear and distinct, and the cardiac boundaries were normal. The skin of her arms, legs and hands presented an appearance resembling ichthyosis. One brother was similarly affected. The skin is said to be smooth during the summer months.

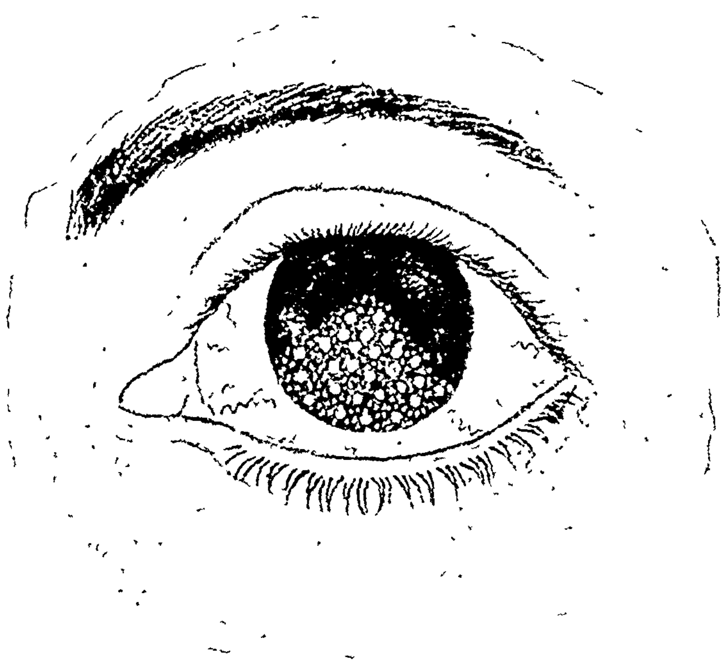

Fig. 3.—Case 3 Early stage of malignant uveitis. Large dots on posterior corneal surface.

Eyes.—V. of R. E. fingers at 50 cm.; slight cyclitis; many dots on the posterior layer of the cornea of large size; the lens opaque and swollen; no view of the fundus; only a red reflex. T. + 1. V. of L. E. 6/5, apparently normal in all respects.

The patient was seen from time to time, without material alteration in the condition of the right eye, on which operation was not permitted. The cataract gradually became complete and vision was reduced to light perception, the dots on the cornea almost disappearing. In November, 1900, although the vision of the left eye was entirely normal, close examination revealed a faint hyalitis and little areas of edematous haze over the fundus, representing spots of serous infiltration in the choroid. The patient was not seen for six months after this, and then, with slight increase in the vitreous haze and the edematous condition of the choroid, the so-called punctate keratitis was evident, the spots not being very large at this time. The patient stated that three months prior to her visit she had had swelling of the right knee which had disappeared.

Examination failed to reveal any lesion in this joint. From this date on to the present time there have been numerous relapses in the left eye with the tendency to form synechiæ, and with each relapse the punctate keratitis has been a little more pronounced and the spots a little greater. The anterior chamber is very deep, but there has been no rise of tension. In addition to the punctate keratitis, the cornea has typically shown the cross-hatched appearance as represented in the diagram (Fig. 6). With the increase in the cross-hatching and punctate condition of the cornea, there has been an increase in the vitreous opacities, which are now dark and floating. The eyeground is difficult to study and shows swollen retinal veins, with fluffy edema of the entire choroid. The visual field is slightly contracted (Fig. 7).

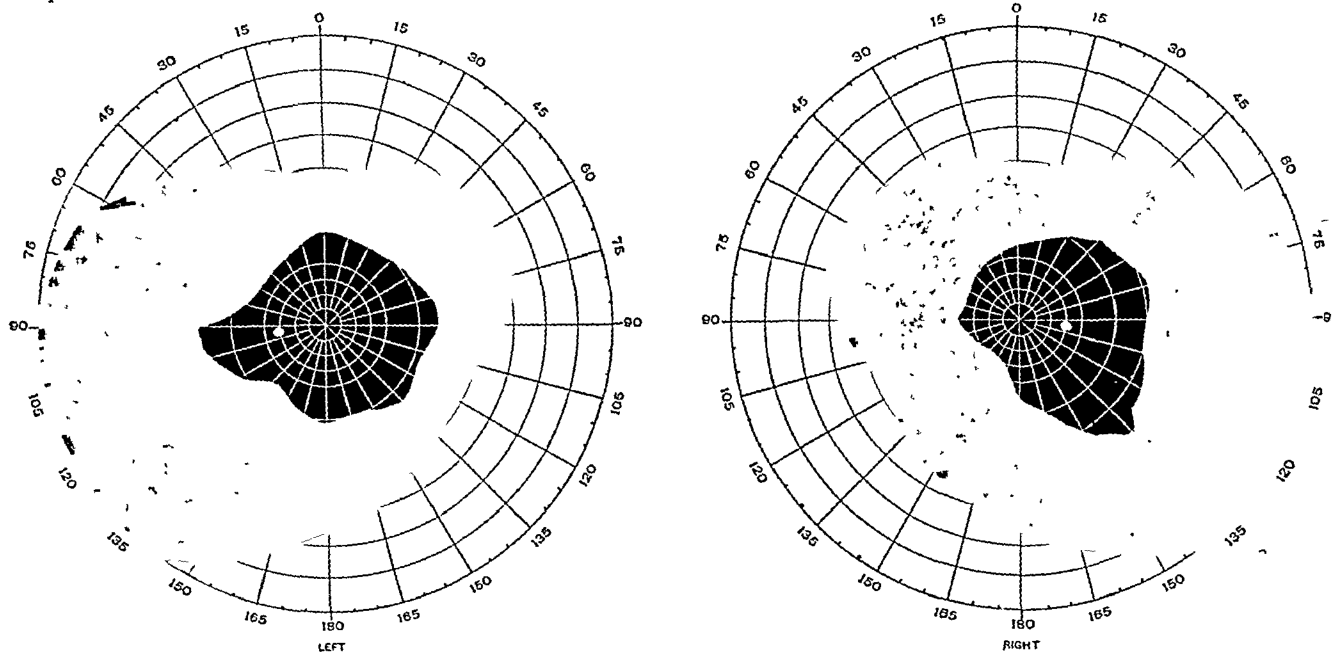

Fig. 4.—Case 2. Visual fields, right and left eye. Malignant uveitis in stage of secondary glaucoma.

The symptoms and, to a certain extent, the lesions which are common to this class of cases are as follows: Some form of choroiditis; extension of the lesions along the choroidal tract until the ciliary body is involved, followed in turn by participation of the iris in the inflammation; frequent relapses, either of the choroidal disease or of the cyclitic disease, or frequently of both; secondary glaucoma owing to obstruction of the filtrating spaces at the angle of the anterior chamber, dependent in part on the outpouring of cellular elements, in part on a change from the serous to a plastic exudate, and in part on the swelling and pressing forward of the crystalline lens, which, as its nutrition is cut off, becomes cataractous. The corneal lesions in these cases seem to have the following characteristics: An unusual size of the deposits on the posterior lamina, which may or may not have a typical triangular arrangement; a tendency for these deposits to become confluent at the lower portion of the cornea and by pressure to invade the cornea itself in the form of an exudate. The size of these deposits reminds one of those which are often seen in the eyes of colored persons, in which descemetitis is apt to be very pronounced. It has seemed to me that uveitis is apt to be more decided in its manifestations in white subjects of the pronounced brunette type.

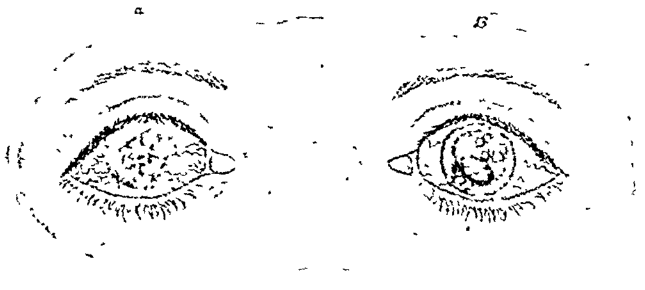

Fig. 5.—Case 2. Malignant uveitis, showing (*b*) large size and coalescence of corneal deposits; (*a*) dense infiltration of the cornea at the end stage of the disease.

In one class of these cases of malignant uveitis the primary choroiditis may exist for a long period, during which it relapses frequently, prior to the involvement of the ciliary body and iris; in another class of cases where the choroidal lesions are much less marked, they are speedily followed by involvement of the ciliary body and iris and improvement and relapse take place in both, but with each recurrence of the cyclitis improvement becomes more difficult and finally impossible because of the disturbance of the nutritive processes in the ciliary body and the stoppage of filtration at the angle of the

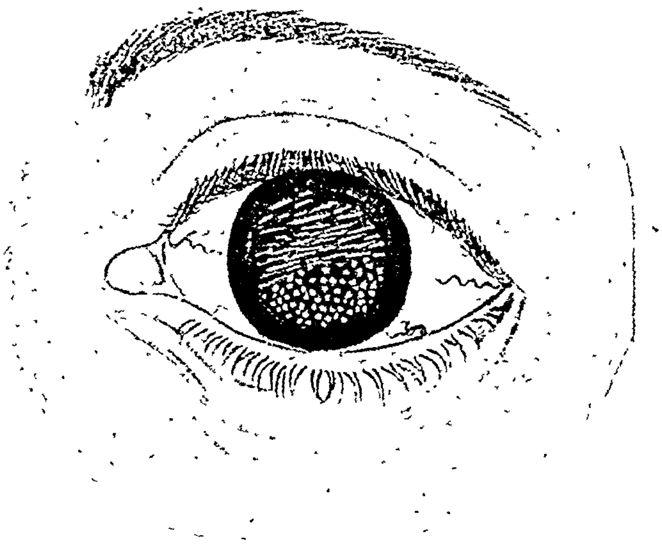

Fig. 6.—Case 3. Uveitis with malignant tendency, showing punctate deposits on cornea and cross-hatching.

anterior chamber; finally, in a third class of cases, the process is a continuous one from the start, choroiditis rapidly becoming associated with cyclitis, to be followed quickly by secondary glaucoma and cataract; in other words, there are no intermissions. This type of the disease may be bilateral and quite as severe on one side as the other, or bilateral, the one eye being blinded by the extension of the inflammatory process, but the other eye saved by a checking of the process in the choroid, or bilateral, the uveitis being malignant from the start on one side and similar in character but less malignant on the other side, that is to say, cataract and secondary glaucoma do not appear.

2. ACUTE UVEITIS BEGINNING AS A SCLEROTICO-CHOROIDITIS, TERMINATING IN MYOPIA AND POSTERIOR POLAR LENTICULAR OPACITY.

This class will serve to explain, I think, some of the cases of myopia which are encountered, particularly when the myopia is very much more pronounced on one side than on the other, the more myopic eye presenting the remains of the storm in the form of vitreous strings and posterior polar opacity.

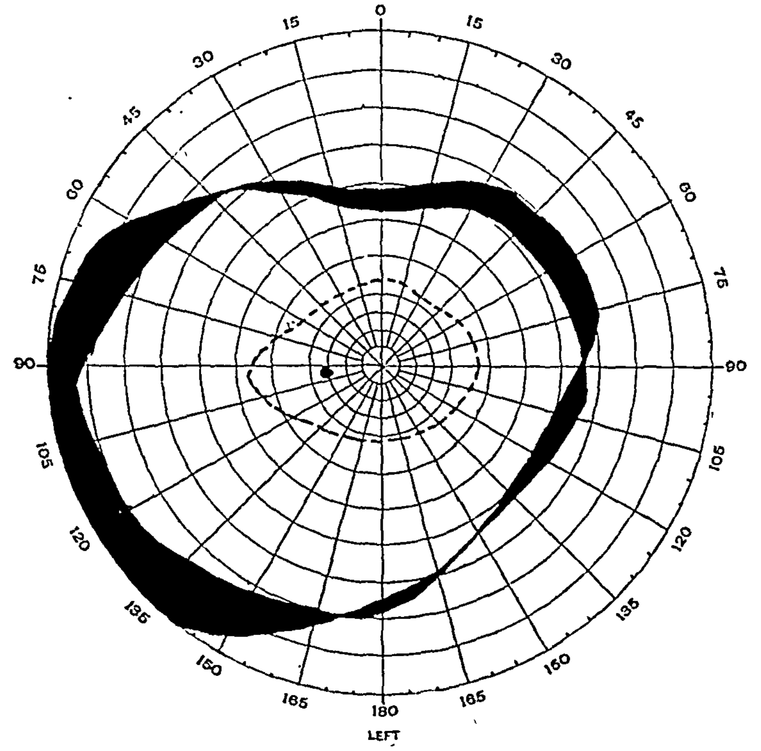

Fig. 7.—Case 3. Visual field, uveitis, with malignant tendency; early stage; slight concentric contraction; general edema of eye-ground.

CASE 4.—J. A. S., aged 22, male, single, born in Pennsylvania, student, consulted me May 2, 1898.

History.—Although never of robust build, the patient has had no serious illness in his life and there is no history of acquired or inherited specific taint. His parents are apparently healthy. During April, 1898, while studying at college, the right eye began to inflame. This inflammation was attributed to hard work and much exposure to artificial light and was unconnected with any illness of a general character.

Examination.—The patient was an under-sized young man of slender build, with pallid complexion and the general type of features which is described under the term scrofulous. Some acne pimples covered the forehead and face and there was a moderate blepharitis of each eye. Physical examination, however, failed to reveal organic disease in any organ. The urine was normal, there was a moderate amount of swelling of the turbinals, most marked on the right side and some tendency to rhinitis, although this did not appear to be of an infectious character.

Eyes.—V. of R. E. 6/50;, typical punctate keratitis and a scleral node of violaceous tint, up and out, about the size of a large pea. The corneal spots were of moderate size and rested on a slightly hazy base. The vitreous was full of dark opacities. The disc was a vertical oval, its edges hazy, the veins full and tortuous, and there was a general edematous haze throughout the entire choroid. The field of vision is illustrated in the accompanying diagram (Fig. 8).

V. of L. E. was normal, the media clear, and there were no changes in the fundus.

Treatment.—The patient was immediately placed upon treatment consisting of mercurial inunctions, ascending doses of iodid of potassium and pilocarpin sweats, and rapidly improved so that at the end of four months the vision of the right eye was 6/15, the scleral node had disappeared and the iridocyclitis had markedly subsided. Then there was a fresh attack with marked exacerbation of the punctate keratitis and increase in the size of the spots on the posterior layer of the cornea. Gradually, under the influence of pilocarpin sweats, iodid and bichlorid of mercury, the cyclitis subsided, the spots became smaller or disappeared, although the vitreous opacities, which were large and dark, continued. Galvanism was then used and subsequently the patient sent to a warm climate.

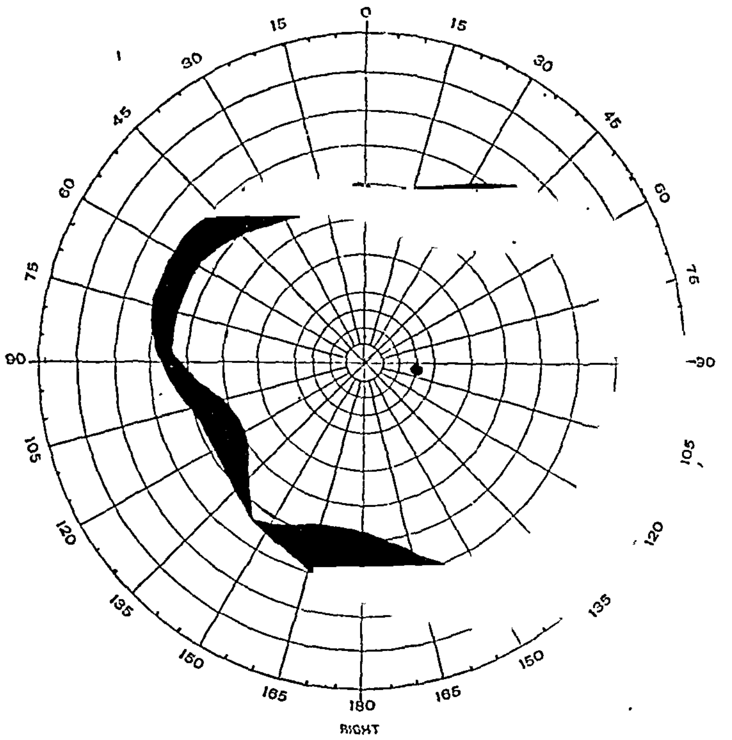

Fig. 8.—Case 4. Visual field, uveitis, beginning as a sclerotico-choroiditis; peripheral contraction; choroiditis also peripheral.

Result.—About a year after the last relapse the media were quite clear, with the exception of some large and stringy vitreous opacities and a suggestive haze around the posterior surface of the lens. The eye had now become myopic and under the fullest mydriasis and in the entire absence of iritis, the neutralizing lens was —5⊂—1 axis 105, 6/15. One year later, with comparatively little change in the refractive error, and with only a few strings in the vitreous, there was a well-marked posterior polar opacity in the crystalline lens, the fundus was clear, the disc a vertical oval, no conus, choroid in fairly good condition. The left eye continued to be normal, and its refraction practically emmetropic.

These cases seem to be characterized in general terms by an area of sclerotico-choroiditis, usually placed well forward, and which is evident in the sclera in the form of a staphylomatous bulging; much hyalitis; comparatively slight involvement of the ciliary body and iris and secondary participation of the cornea, upon which the usual deposits appear in moderate degree. Relapses are not uncommon, but under vigorous treatment the eye quiets with the lesions already described, namely, a certain amount of vitreous change and a posterior polar opacity. Doubtless when the area of sclerotico-choroiditis is far forward the involvement of the ciliary body is quickly manifest through an extension of the process, but the entire choroid is also sufficiently affected to permit a distention of the eyeball and a consequent increase of refraction.

3. MILD, CHRONIC, SENILE UVEITIS, ASSOCIATED WITH ANTECEDENT OR SUBSEQUENT HEMORRHAGES IN THE VITREOUS.

That there exists a mild type of uveitis often seen in elderly subjects, characterized by fluffy areas in the choroid, fine hyalitis, a few spots, almost translucent in appearance, on the posterior surface of the cornea, without involvement apparently either of the ciliary body or of the iris, the pupils remaining perfectly active, is, of course, a very common observation and the symptoms described a familiar picture. The association of retinal hemorrhages, or hemorrhages which burst through the hyaloid into the vitreous is less commonly described and observed.

Case 5.—Mrs. G. R. B., aged 52, born in America, consulted me first on April 8, 1894.

History.—There is nothing noteworthy in the patient's early history. She had the usual illnesses of childhood, but was in all respects a healthy girl and young woman, except that she suffered from headaches. For the relief of these she was given glasses when twenty years old to correct a high hypermetropic astigmatism. She married young, and has given birth to eight children. Six are living and healthy; two died of scarlet fever. There is no history of influenza. She has occasionally had spells of rheumatism, has suffered sometimes from lumbago, and to use her own expression, "is always taking something for indigestion." She has had much worry during her life, largely owing to her husband's inability to cope with his responsibilities and from the fact that he suffered from epilepsy, his attacks, according to his physician, having been brought into control by the use of mercury. Other than this, however, there is no possible hint of specific infection in this patient.

Examination.—The patient is a well-preserved woman, of good figure and physique, and general examination has failed to reveal any organic disease save only the indigestion before referred to and the tendency to attacks of rheumatism, the word rheumatism being used in the vague sense so constantly given to it. The urine examination was negative; blood examination was not made.

Eyes.—V. of R. E. with correcting glass 6/9. Numerous rather fine translucent dots were present on the posterior surface of the cornea, with fine vitreous spots; the disc margins were slightly hazy; the veins were full; the irides prompt in their reaction to light; the anterior chamber deep; and the tension normal.

V. of L. E. with correcting glass 6/9, and an almost exactly similar condition in the cornea and fundus. Somewhat more careful examination a day or two later, after dilatation of the pupil, revealed faint cortical opacities in the periphery of each lens, and between the disc and the macula slight choroidal changes in the form of streaks of erosion. Until the end of the year 1901, or in other words, seven years, the patient was under constant observation, with practically little or no change in the conditions noted. Occasionally the spots on the posterior layer of the cornea would be a little more marked than at other times and the vitreous opacities a little more pronounced. They never entirely cleared away, but also never produced any very serious alteration of vision. Indeed, with full correcting lenses the vision in the right eye was normal and in the left eye 2/3 of normal. Ciliary injection, synechiæ, and inflammatory signs in the iris have never been present.

On the first of January of the present year, after a particularly prolonged season of nursing her sick hu
after reading an unusual amount, dull vision su
peared in the right eye. On examination the vitreous was found entirely filled with large blood-clots.

Treatment and Results.—Under treatment (iodids, mercurials, sweats, etc.), the vitreous entirely cleared, and on the 14th of the past month her vision was 6/9 in that eye and in the opposite eye it was about 6/15. At no time was there any particular change in the visual field, which was normal both peripherally and centrally. After the absorption of the clot, the moderate deposition of dots upon the posterior surface of the cornea was about the same as it had been prior to the hemorrhage, and the only change noted was the very full, dark, somewhat tortuous veins, with signs that they were being pressed on by the arteries.

Case 6.—M. H., aged 48, female, single, born in Pennsylvania, consulted me first Feb. 24, 1902.

History.—There is nothing of consequence in the patient's history except that she is very rheumatic, or perhaps, more accurately, lithemic. This condition also obtains in members of her family. One brother has had numerous attacks of episcleral congestion of undoubted gouty origin, and is deaf, probably due to gouty changes in the ear. The patient herself, *however, has been in fairly good condition,* and except for a high astigmatism, has had fairly good eyes. Through her life, and especially recently, she has had much sorrow and has been greatly worried and mentally depressed. In October, 1901, she began, while reading at sea, to have spots and flashes before her eyes, followed a short time afterward by loss of vision. When examined she was told that she had had a hemorrhage burst into the vitreous.

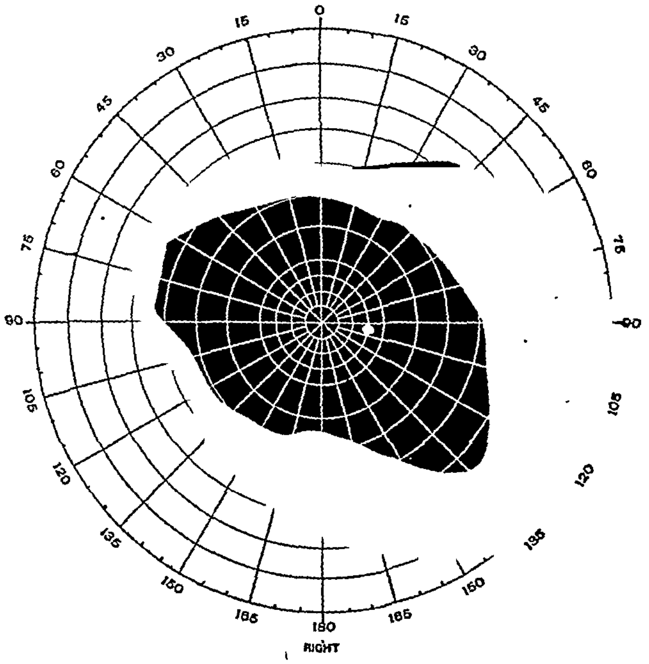

Fig. 9.—Case 6. Visual field, uveitis, following retinal hemorrhage; peripheral contraction; test-object two candles.

Examination.—The patient is a well-formed woman, who gives no external evidence of disease. Examination of the heart and lungs failed to reveal any signs of disease. The blood examination was as follows: Blood fairly good color; coagulation normal; hemoglobin 66 per cent.; red blood corpuscles 3,920,000; leucocytes 7200; no poikilocytosis. The urine examination was as follows: Specific gravity 1018; no albumin; no sugar; urea 1.88 gram per 100 cm.; no casts; no renal epithelium; a few cylindroids.

Eyes.—V. of R. E. fingers doubtfully in the outer field; no fundus view, the entire vitreous being obscured with large dark masses, through the rifts of which a very faint red g
could be obtained. The *pupil* was normal, the anterior ch
ber normal; no rise of tension. Field according to the diag
(Fig. 9).

V. of L. E., after the correction of a simple hypermet
tigmatism, 6/6(?); media clear; round disc of fa
r; physiologic cup; no fundus lesions.

Treatment and Results.—The only indication for treatment apparently was the simple anemia which the blood count showed, and to which the hemorrhage was ascribed. Remedies, however, failed to make any impression, but on April 4 the patient appeared stating that she had had a little pain in the eye. Mild ciliary congestion was evident, with three or four delicate synechiæ and a typical deposition of fine dots upon the posterior layer of the cornea resting upon a hazy surface. The synechiæ readily yielded to the influence of atropin, but the blood clot in the vitreous was unchanged at the last examination.

It would seem that there are two classes of these cases. In one a mild uveitis, the lesions of which are confined almost entirely, or perhaps entirely, to the choroid, exist for years, iris and ciliary body remaining uninvolved although hyalitis is pronounced. Suddenly hemorrhage bursts into the vitreous, coming either from the ciliary or from the choroidal vessels, it is practically impossible to determine which. The effused blood absorbs perfectly under the ordinary regimen and leaves the eye in practically the same condition that it was before the hemorrhage. In another class it would seem that the ordinary hemorrhages which burst into the vitreous precede by a considerable period of time, it may be months, the appearance of the uveitis. Under these circumstances the hemorrhage in the vitreous is much more pronounced, that is to say, it fails to yield to ordinary treatment, and is followed by descemetitis with involvement of the ciliary body and iris. Significant symptoms in the fundus in cases of this character, when the fundus can be studied, are, in the first place, large tortuous veins pressed on by slightly sclerotic arteries, moderate haziness and swelling of the margins of the disc, and particularly fluffy islands of small exudate and edema, often lying far out in the periphery of the eyeground and chiefly situated along the vessels of larger caliber; rarely small capillary hemorrhages in similar situations.

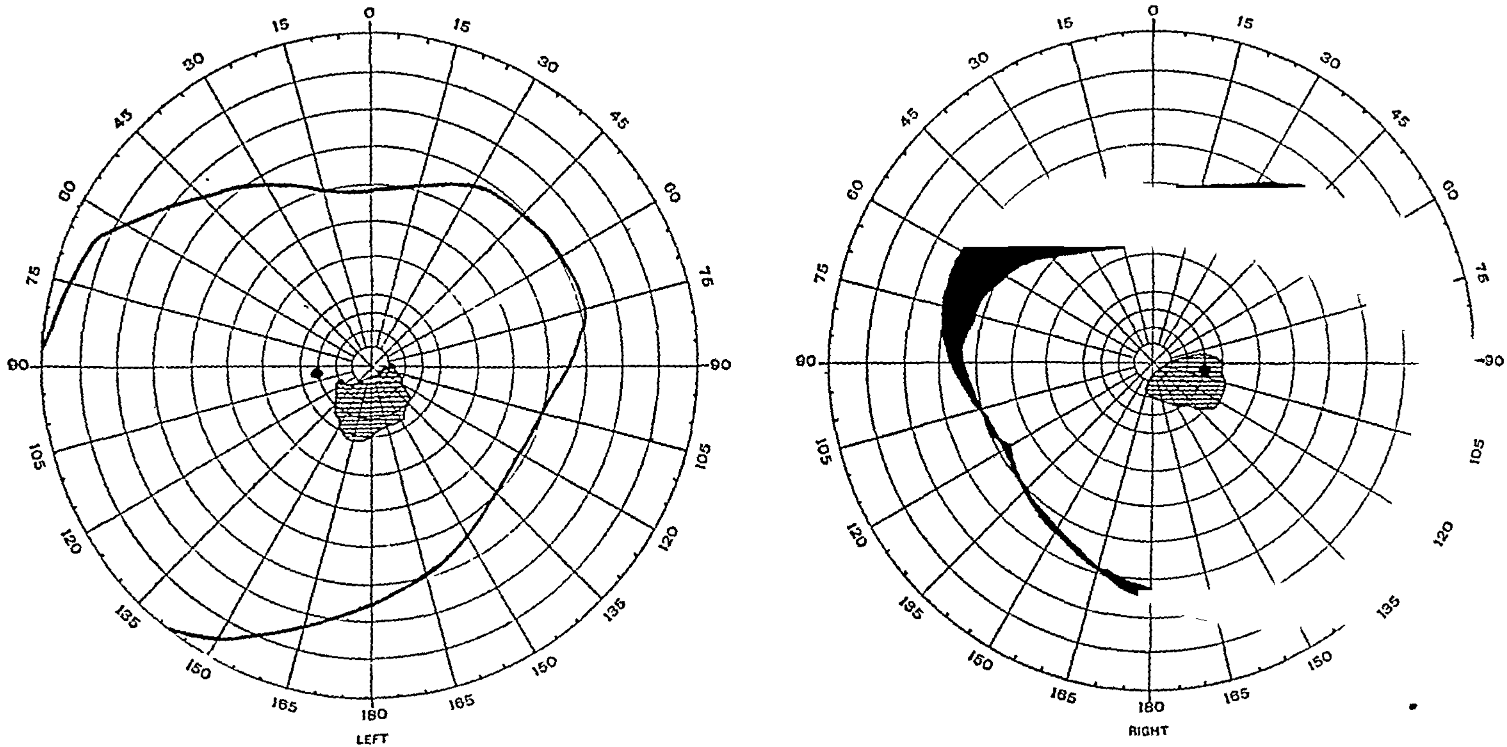

Fig. 10.—Case 7. Visual field, uveitis of gouty origin; negative scotomas in center of fields.

4. RELAPSING PLASTIC UVEITIS BEGINNING INSIDIOUSLY IN GOUTY AND RHEUMATIC SUBJECTS.

The relapsing iritis so commonly ascribed to gout and rheumatism and so frequently encountered, is not exactly the type to which reference is made under the present heading. Certain cases are offered in illustration.

Case 7.—Mrs. H. C. H., aged 55, born in Pennsylvania, consulted me on November 3, 1897.

History.—There is nothing of interest in the patient's early history. She comes from a sturdy line of ancestors, all of whom, however, have—to speak in general terms—been gouty. Her children are healthy and exhibit no signs of disease. She herself has suffered from vague pains, and after middle life was greatly afflicted with pain in the sole of her foot and the arch of her toe, which was attributed to gout. She has been in the habit of leading a rather lazy life so far as physical exertion is concerned, but has been mentally very active. On November 7, 1897, she began to complain of flitting clouds and specks before the right eye, which soon made their appearance before the left eye also.

Examination.—The patient was too stout and moved with some difficulty, owing partly to her disinclination to make physical exertion and partly to the pain which walking occasioned in her feet. Repeated examinations by the most skilful physicians failed to detect the slightest evidence of disease in her heart, general circulation or kidneys. In general terms, however, these examinations did reveal an excess of uric acid.

Eyes.—V. of R. E., after the correction of a slight hypermetropic astigmatism, normal; the disc was oval, of fairly good color, the veins full and irregular, with a slight tendency to beading. There was a faint grayish haze throughout the retina and some superficial choroidal disturbance (epithelial choroiditis).

V. of L. E. normal and exactly similar ophthalmoscopic conditions; media of both eyes clear; pupil reactions normal. Two months later the muscæ had assumed the appearance of clouds, somewhat orange-colored, and an examination of the field of vision revealed perhaps slight concentric contraction and almost symmetrical color scotomas, situated slightly below and more to the temporal than to the nasal side of the fixation point (Fig. 10).

Subsequent History.—The patient was not seen again until Oct. 21, 1898, when she returned with the history that while abroad and on the 2d of April, that is to say, three months after the last examination, she developed iritis. She was treated in France and England and from her English physician I know that when he first saw her the signs were only those of iritis or iridocyclitis, but later on, that is to say, just prior to her return to this country in October, deposits on Descemet's membrane, the so-called punctate keratitis, were easily visible. Peripheral choroiditis, nowever, was not at that time demonstrated. When examined again by me the right eye showed well-marked uveitis, punctate spots on the cornea, hyalitis, fogginess and edema of the choroid, and great distention of the retinal circulation. V. = 6/50. In the left eye V. = 6/5; the remains of synechia below; some faint vitreous haze; a few spots on the posterior surface of the cornea.

From that date until June, 1901, this patient has had numerous attacks and relapses, sometimes in one, sometimes in the other eye, and a few times in both eyes. The attacks always begin with clouds followed soon by slight ciliary congestion, the formation of synechiæ if not prevented with atropin, increase in the hyalitis and marked increase in the punctate deposits on the cornea and the cross-hatching in this membrane. Since the last date noted there has been no attack, the good result apparently being largely due to systematic treatment by baths in the *Hot Springs.* Vision is now normal in each eye, although there are still faint opacities on the posterior surface of each cornea, most marked upon the right side, and a few fine vitreous changes.

Case 8.—Mrs. J. S., aged 47, born in the United States, consulted me Oct. 17, 1901.

History.—There is nothing in the patient's early history which bears directly upon her subsequent ocular disturbance. Her chief illnesses apparently occurred after she was grown up and after her marriage. She has always been typically rheumatic. Some six or seven years ago she had an attack of rheumatism lasting for a long time and treated with large doses of salicylate of sodium. To this drug the patient attributed much of her deafness, which was very pronounced and which had been associated with middle-ear disease and chronic naso-pharyngeal catarrh. She has had several operations on her nose, probably removal of hypertrophied turbinates. She has also had some abdominal operation the nature of which was not definitely ascertained, probably an ovariotomy. One year ago she suffered much from furunculosis, and in the winter of 1900 from severe influenza. The patient's father is dead; her mother is living and healthy; one sister is living, who is also very rheumatic. The patient's eyesight has always been good; indeed, she has prided herself upon her good eyesight until May, 1901, when she suffered from flitting episcleral congestions. These were attributed by her attending physician to eyestrain, co-incident with beginning presbyopia and glasses were ordered. From time to time these ocular congestions recurred, but were unassociated with severe pain until about three or four months later, when violent pain occurred. The eyes, however, were examined at that time by an expert ophthalmologist, and according to the patient's statements, no very good reason for the pain was discovered. From August, 1901, until the middle of October, 1901, the patient seems to have suffered from frequent attacks of ocular congestion, but did not consult any one for her relief.

Examination.—The patient is a good-sized, very blonde woman, with pallid skin and slightly bluish lips. The heart sounds were feeble, but there were no murmurs or signs of organic disease. Examination of the urine was as follows: Specific gravity 1022; albumin none; sugar none; urea 4.5 grains to the fluid ounce; urates not increased; chlorids normal; phosphates greatly diminished; sulphates slightly increased. In the sediment were found many pus cells and much bladder epithelium and mucous shreds; many cylindroids but no true casts. The patient was quite deaf, being able to distinguish only very loudly-spoken words. There was well-marked atrophic rhinitis.

Eyes.—V. of R. E. 6/15; well-marked punctate keratitis, the spots being somewhat irregularly placed and not of very great size; anterior chamber about normal in depth; thick irregular synechia, firmly attaching the edge of the pupil to the iris. The disc was vertically oval in shape. No special changes could be discovered in the fundus; opacities floated in the vitreous.

V. of L. E. 6/22; similar conditions, with the exception of much more marked synechia and plastic exudate binding down the pupillary area.

Treatment and Results.—From the middle of October until the middle of March, the patient suffered numerous relapses, sometimes in one and sometimes in the other eye, lasting from a few hours to five or six days, and always accompanied by the most excruciating pain. All manner of treatment was tried—inunctions, sweats, the iodids, salicylates, leeching, coal-tar products, etc. All of them were unavailing except the salicylates, or some anti-rheumatic remedy. These always controlled the attacks. On a few occasions, when they were very severe, recourse was had to morphia. Always during the attack there was marked increase in the bulbar injection, great increase in the corneal haziness and deposition of the corneal dots, with such great tenderness in the ciliary region that it was difficult to ascertain anything by palpation. Gradually the violence of the attacks subsided, and by the middle of March, although the synechiæ, previously described, which had been so plastic in type that they had been utterly uninfluenced by the mydriatics, remained, the eyes were white and quiet and vision, with suitable correction, was 6/9 in each. The patient was then sent to the *Hot Springs* for a cure, where she remained for two months. Since then there have been fewer recurrences of the attacks, but the pupillary spaces are so much blocked with lymph that iridectomies are urgently required.

The approach of this type of the disease, which I have ventured to denominate insidious, is from two regions. In one class of cases the primary lesion appears in the fundus in the form of an ill-defined choroidal change, or patches of ill-defined choroiditis, while the visual field, but little contracted in its periphery, presents in various portions of its center ill-defined scotomas, and the patient is seriously annoyed by obscurations in the visual field and various types of muscæ, although vitreous change can not be found at this time and direct vision may be normal. Later, it may be months afterwards, the first signs of iritis appear, or more accurately, iridocyclitis, followed sooner or later by the punctate deposits on the cornea, the vitreous changes, etc., the exudate in the pupil space assuming a distinctly plastic nature, so that unless atropin is promptly and speedily used the iris is bound down to the lens capsule by firm synechiæ. Case 7 illustrates this type of the disease very well. In the second class the first symptoms which ought to call attention to the disease appear in the form of flitting conjunctival episcleral congestions, the "hot eye" of Jonathan Hutchinson, the "vasomotor dilatation of the vessels" of Swan M. Burnett, and the "fugacious periodic episcleritis" of Fuchs. That singularly acute observer, Jonathan Hutchinson, long ago stated that this conjunctival, or conjunctivo-scleral condition, might be antecedent to an inflammation of the iris and ciliary body, which, when it comes, may assume the typical relapsing character, associated with corneal lesions and dense vitreous exudates and thick plastic material in the pupil space, which is described in Case 8. Had this patient's condition been recognized when she first applied for treatment, as is described in her case history, months, certainly weeks, before the iritis appeared, her subsequent serious suffering might have been avoided.

Cause of Reddening of Carbolic Acid.—F. T. Gordon (Proceedings Penn. Phar. Asso.) sets forth that recent investigations indicate that the cause of the reddening of carbolic acid is the ozone or hydrogen peroxid of the air acting in the presence of iron, derived from the glass of the bottles or the tin of containers. Like the coloration of resorcin and hydroquinone, this reddening is the effect of the two substances, iron and hydrogen peroxid, acting together; the latter is formed from the slow oxidization of the iron (in bottles or in the substance itself) in the presence of air and moisture. Experiments corroborate this theory.—*Western Druggist.*

ANALYSIS OF THIRTY-SEVEN CASES OF UVEITIS.*

HIRAM WOODS.
BALTIMORE.

The form of uveitis I propose to consider is choroidocyclitis. The cases, with two exceptions, were seen in private practice. They divide themselves naturally into those with and without descemetitis. This was found in twenty of my thirty-seven cases: two of serous iritis and eighteen of choroiditis with descemititis. The closest description I have found in text-books of this form of choroiditis is by A. Hill Griffith in Norris' and Oliver's "System." Under the heading "Anomalous Forms" he describes a "Choroiditis with Descemetitis." He had seen forty or fifty cases, chiefly in young women. His explanation of the descemetitis is: "The dots on Descemet's membrane are formed in the choroid, set free in the vitreous and carried by the nutrient currents of the eye to be deposited on the back of the cornea, which view necessitates the permeability of the suspensory ligament by solid particles."

As to causation, syphilis was never found. Anemia and *tuberculous family history* were sometimes present, and the cases treated accordingly; but in many the cause was undetermined. My own cases confirm this difficulty of fixing a cause. In giving as "causes" associated life epoch or functional defect, I mean only to suggest such inference as can be drawn from association in a number of cases. As descemetitis is the boundary between this and other forms of choroiditis observed, it may be well to state the method of looking for it. This was direct examination, aided by the 20-D. convex lens. Mydriasis, by furnishing an illuminated background, brings the spots into prominence. In a few cases, seen very early, the dots were not found, but appeared by the second or third day. Nor were they transient, lasting two or three weeks. General muddiness of vitreous, in distinction from a fairly clear chamber with large or fine opacities, hyperemic disc and plaque-like white or yellow deposits somewhere in the fundus were uniform. A striking feature was the small number showing retinal hemorrhages or marked implication of retinal vessels. In only three was retinal hemorrhage found. The exudate was choroidal. In two cases, examined several months after the attack, no trace of exudate was found. In such others as afforded late inspection there was atrophy. Subjectively, all presented the same initial symptom: sudden loss of visual acuity, varying from cloudy appearance of objects, with test vision of 20/40 or less, to positive peripheral or central scotoma, or seeing only moving hand. Maximum loss came quickly. Improvement was very gradual and slow, being noted as late as a year after the attack. In twelve of the twenty cases vision normal or as good as 20/30, was ultimately obtained. The paracentral atrophy observed in many of these cases was strikingly inconsistent with such vision. The scotoma was negative, and the eyes functionally satisfactory. Permanent vitreous opacities and central atrophy accounted for visual defect in others.

Omitting for the moment the two cases of serous iritis in girls of 15 and 16, there were eighteen cases of this form of chorioditis, seven male, eleven female. Five male and seven female presented primary, two male and four female relapsing attacks. Of the eighteen cases the site of acute exudate, or atrophy from former attacks, was central or paracentral in ten, peripheral in eight. In *relapsing* cases the second or later exudate adjoined atrophic spots.

Etiology is best studied with sex and age. There was no reason to suspect syphilis in any of the cases. Nor could I get a history implying tuberculosis. Of the five primary male patients, one, age 23, developed a large peripheral exudate a week after trauma—blow from end of a ladder. In two, 22 and 27, no cause was found. The patients were reliable business men, apparently in perfect health. Neither in them or in any of these patients was there tendency to myopia, or other chronic degenerative changes. A fourth, 23, had suffered from chronic constipation for years; but this was the only trouble found. Seven years have passed since this attack, and he has had no relapse, or shown constitutional disease. The fifth, 25, seen in '94, with right central exudate, had a tapeworm at the time, and was of frail build. He was not tuberculous, and has not, I believe, developed it since. In June, 1901, while I was at the St. Paul meeting, this young man had a relapse in same eye, and was attended by my friend, Dr. Randolph. During the past winter he underwent operation for appendicitis. In two remaining male patients, who had relapsing attacks, two and eight years after primary, no cause for latter was found. The ages were 16 and 38. Thus, in these seven male cases in but one was a definitely recognized cause found—trauma. Associated gastro-intestinal disorder was an accompanying condition in two, and nothing was discoverable in the others.

Of the seven primary female cases one, 50, was rheumatic. She presented to a marked degree rapid opalescence of the lens during, and persisting for sometime after the attack. Peripheral striations found in a previous examination for refraction, were not affected. A second case, 39, followed traumatism—blow from a piece of wood, in two weeks. It is noteworthy that failure of accommodation seemed the earliest symptom. When I saw her after two months, there was 20/20 central vision, with peripheral scotoma, corresponding to exudate. A third, 36, was seized with central choroidal exudate while sewing. No cause was found. In a fourth, 37, sympathetic ophthalmia seemed the most likely explanation, though a severe attack of grippe, immediately before the eye trouble, may have had influence. The right eye had been lost eight years previous, after puerperal fever. The globe was shrunken, with opaque cornea, and obliterated anterior chamber. When I saw the patient this atrophied ball was injected, painful to touch, and had been so since the grippe. The left eye had normal central vision; but ciliary injection was present. Pupil was, if anything, hypersensitive. The next day descemetitis appeared, and two days later a faint peripheral choroidal exudate with scotoma in upper and inner field. Recovery after enucleation of right eye was complete in three months. The primary attack in the other seven female patients occurred in the second decade of life. Adding to these the two cases of serous iritis, there are thirteen cases in the female sex, in nine of whom uveitis made its first appearance during the early years of menstrual life, this function being, so far as known, normal in four, abnormal in five. Three of the four relapsing cases were under the care of gynecologists. It is impossible to say whether the pelvic trouble causes the eye lesion or if both are due to some hemic or other influence at present unknown.

To summarize: This form of choroiditis seems to differ from others, 1, in ophthalmoscopic appearances; 2, mode of onset and early symptoms; 3, etiology, so far as we are aware: 4, prognosis. Some of them get entirely well by absorption of exudate, but, especially if atrophy remains, there is great danger of relapse. This may continue indefinitely, but so long as the fovea is spared, useful vision remains. A woman of 42 gave history of six attacks, during each of which she was practically blind; yet, in spite of numerous atrophies she had normal central vision. It is also noteworthy that in but one of the eighteen cases were both eyes involved.

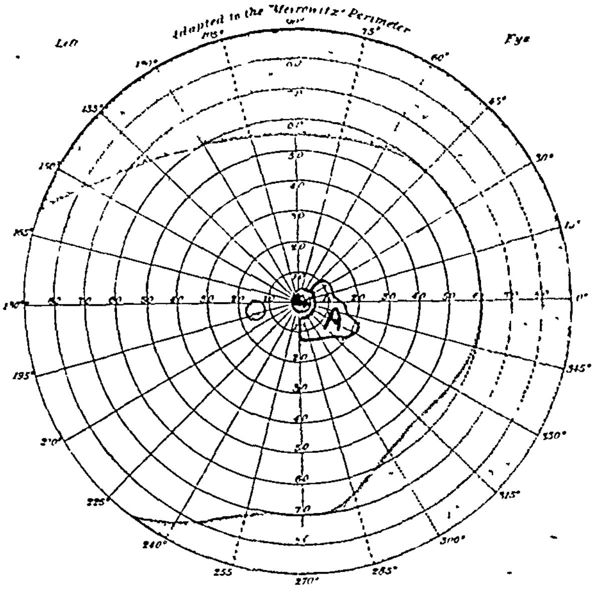

Fig 1.—A Paracentral scotoma corresponding to fundus lesion. Field limits normal.

Of the seventeen cases without descemetitis syphilis was present in three, while a fourth showed typical foveal changes, though neither history nor other evidence pointed to systemic infection. In the three, periods of two, six and nine years had elapsed since the initial lesion; considerably beyond the usual time for secondary eye symptoms. Interesting queries are: how recent should infection be to justify causative relation, and, are the syphilitic foveal lesions sufficiently characteristic of this, in distinction to other forms, to justify diagnosis in absence of history or other manifestations? In these, in two cases of choroiditis disseminata and five with subretinal extravasations, visual impairment was confined to the field area corresponding to fundal lesion. Scotomata existed in eight, macropsia in one, photopsia in two; symptoms characteristic of choroidal disease. Causes, so far as determined, were syphilis in three, unknown in the fourth with specific changes, and gout in both cases of the disseminated variety. Hemorrhages occurred in two old patients who had atrophies, one during convalescence from pneumonia, a fourth in connection with severe asthenopia, the fifth coincident with menstrual suppression.

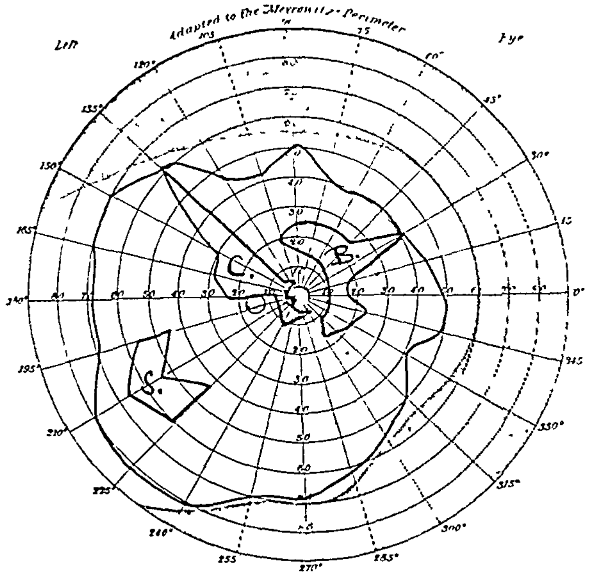

Fig. 2.—B and C Areas of color scotoma and dim white perception S Absolute transient scotoma. Field limits narrowed.

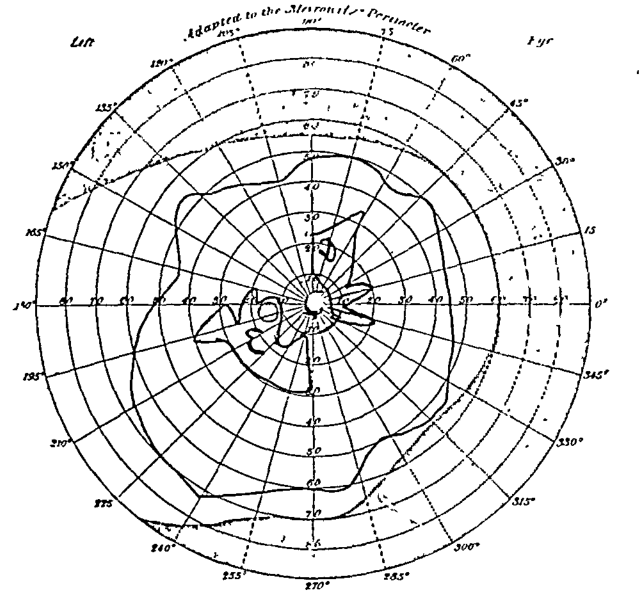

Fig. 3.—E and D. Shape of color scotomata and dim white areas.

I shall use the remaining six patients as a basis for inquiry into the diagnostic and prognostic significance of the symptoms of so-called "choroidal hyperemia," and vitreous opacities. In Griffith's excellent article, already mentioned, the indefiniteness of symptoms of choroidal congestion is dwelt upon, reddened disc being practically the sole sign. This comes through cilio-retinal anastomosis. He says: "Even patches of localized inflammation may not be discoverable till they have broken through the hexagonal pigment layer of the retina." Concerning vitreous opacities, he says: "They are often absent through the entire course of the disease.

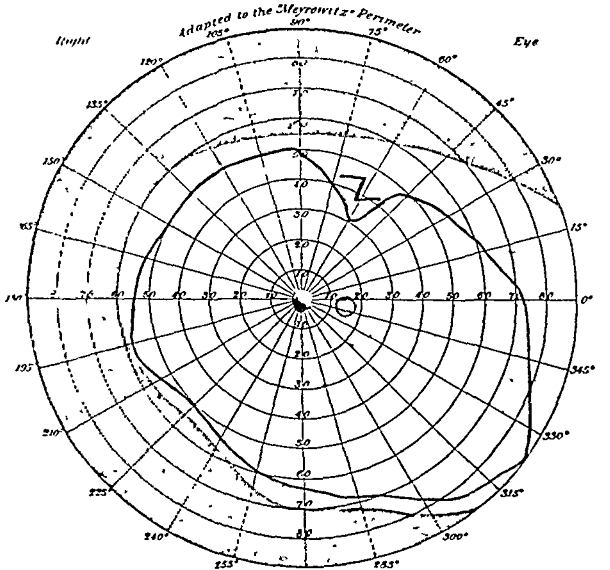

Fig 4.—Narrowing of upper temporal field with decided "cut-in."

Their presence depends on the coincident implication of the retina rather than upon the choroiditis itself, and they are found *only where the retinitis* is more marked than usual, and the inner layers are affected, as shown by opacity of the retina and blurring of its vessels." He regards "the retinitis as a separate process, from the same cause which produces the choroidal trouble, and not as an extension of the latter." I cannot resist the conviction that the statement concerning vitreous *opacities appearing only in connection with* opacity of the retina and blurring of its vessels will not tally with general experience. I am sure I have seen intensely red disc and muscæ without involvement of retinal vessels. I have such a case now under observation: a lady 32 years old, with simple myopic astigmatism, normal central and peripheral vision. Red discs and floating bodies were apparent *on first examination* a year ago. Refraction correction seems to have relieved the choroidal hyperemia, if such was the meaning of the red disc; yet fine vitreous opacities are still observable, and the eyes are not capable of prolonged work. A boy of 19, student at Johns Hopkins University, whom I examined six years ago, had the same intraocular appearances in an eye in which he had a positive scotoma in the upper temporal field. Central vision was unaffected. Symptoms had followed unusual eye work, and recovery came after a few months' rest. I have had under observation for ten years or so a lady in the fifties who has persistently complained of muscæ in the right eye. Central and peripheral vision have been normal. Several times have I noted this reddening of the disc, and fine vitreous opacities when reviewing her glasses. In March she came with a choroido-retinal exudate. Some influence, apparently rheumatic, has kept the eye sensitive and finally produced ophthalmoscopic choroido-retinitis.

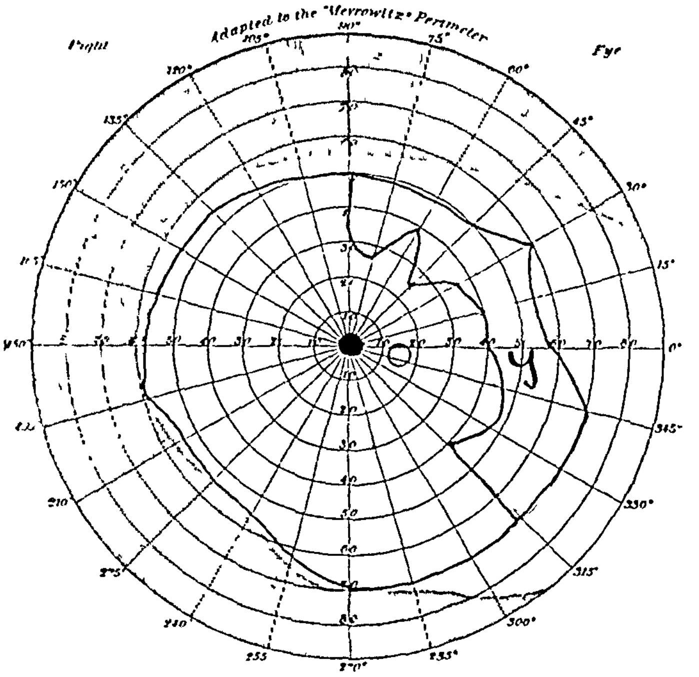

Figure 5

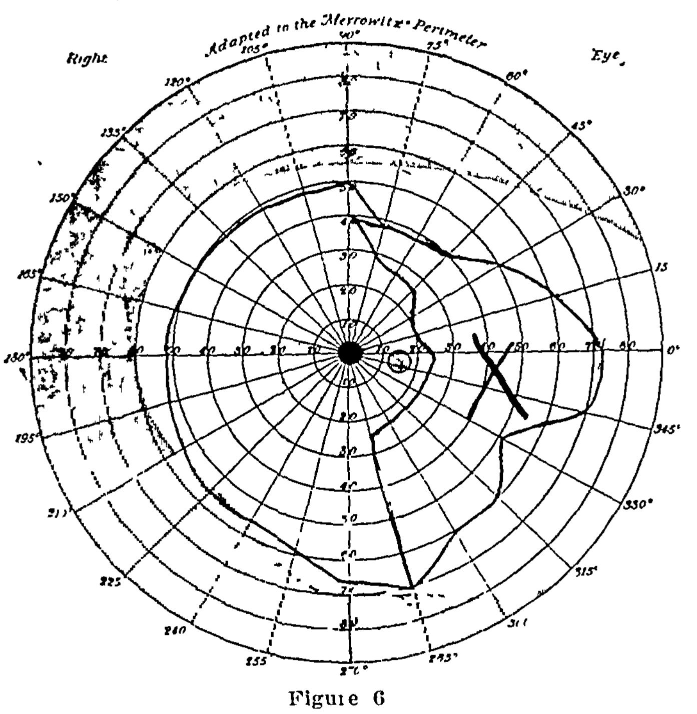

Figure 6

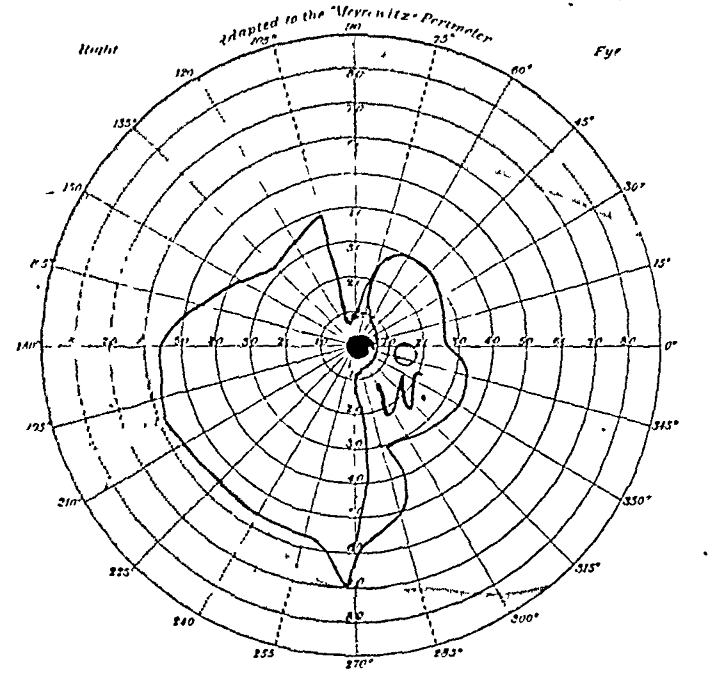

Figure 7.

Figs 5, 6, 7 show progressive narrowing of right temporal field; letters Y, X, W, color scotomata and dim white areas always preceding loss of portion of field

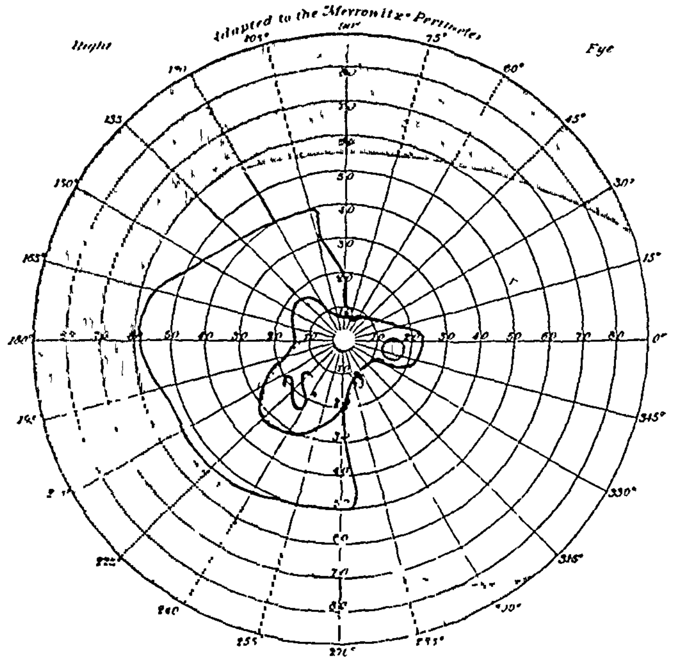

Fig 8 – Only a little temporal field left Nasal field contracting Space V, color scotoma, as in other figures, encroaching well into nasal field

In the following three cases changes followed each other in such rapid succession as to leave no doubt that the red disc and vitreous opacities meant serious trouble. A lady, 31 years of age, was seen in December, 1900, for defective central vision in the left eye. She had consulted another oculist a month previous, who had found choroiditis, and given an unfavorable prognosis. Vision was 20/70, with a paracentral scotoma (Fig. 1). Red disc, floating vitreous opacities and perifoveal pigment heaps were present. In eighteen months fundal appearances have not materially changed. In March, 1902, she thought this eye was getting worse. Examination showed a peripheral positive scotoma and two field areas in which colors were lost and white was dim (Fig. 2). On May 27 the shape of the dim areas had changed, and scotoma disappeared (Fig. 3). In the right eye, which was examined and found normal in December. 1900. visual changes have progressed. In February, 1901. she complained of pain, which yielded to atropia. Vision was 20/15, field normal, but accommodation had fallen off. She needed +2 D. to read 1 Jaeg. I found a few small muscæ in the anterior vitreous, and reddened disc. A month later a small choroido-retinal exudate was found in lower nasal fundus, only after careful search, and field examination had demonstrated narrowing up and out (Fig. 4). From this there have developed in the temporal field dim areas as described above. soon becoming scotomatous and gradually approaching the fovea (Figs. 5, 6 and 7). Central vision was affected only after nine months, when it was 20/30, with complete loss of temporal field. The dim area has now crossed into the nasal field, and central vision is reduced to 20/70 (Fig. 8). Only hyperemic discs, floating bodies in a clear vitreous and insignificant peripheral changes have been found. It seems to me that atrophy of the retinal cells is the only explanation dependent upon a pre-existing choroiditis, possibly, or an independent retinal affection from the same cause which produced the signs of choroidal hyperemia, as held by Griffith. In this case no cause was found. unless it was an offensive post-nasal catarrh. It is possibly worthy of remark that the father of this lady once had what was called "hyalitis," from which he recovered. He himself. a very intelligent man, while understanding the causes of such things, could throw no light on the etiology in his own or his daughter's case.

The two other patients were men. 37 and 40, both in robust health, free, so far as could be determined. from syphilis or tuberculosis, one a farmer, the other a country merchant. Both consulted me for the same symptoms—asthenopia in reading and muscæ. Both eyes were involved in one, the muscaæ being seen only by the left eye in the other. Central and peripheral vision was normal in the first case in both eyes. The discs were red. vitreous, cloudy and contained many opacities, but no fundal exudate or hemorrhage was found. In a few months both eyes had detached retina and secondary cataracts formed later. Removal of these has given ability to walk alone. The other man of 40 presented similar red discs with vitreous opacities. The left eye presented a small peripheral retinal extravasation Central vision was 20/20 R., 20/70 L. E. The right eye has developed only defective accommodation found at first. With emmetropic refraction he needs at 40 +1. for near. The left eye is lost. save in lower periphery of field, by detached retina and vitreous clouds. Here, then, are six cases, all free from syphilis, tuberculosis, central lesion or suspicion of toxic disturbance. All showed the same initial fundal lesion, red disc, the accepted sign of choroidal hyperemia and vitreous opacities. In three there was abnormally low accommodation. One had no lessening of visual acuity. one a scotoma which disappears with rest. a third developed, after years, an exudate. Three patients lost useful sight by retinal atrophy or retinal detachment.

To conclude, the 37 cases indicate: 1. That menstruation, in its establishment, or later, if abnormal, intestinal disorders, acute infections and nasopharyngeal disease should be reckoned among possible causes of plastic choroiditis. Whether or not these conditions are themselves direct causes or lower resisting powers and so enable other causes to act, is uncertain. Nor can it be definitely said that some of these coincident conditions may not themselves be manifestations of recognized causes of uveitis; rheumatism. anemia and the like. 2. These cases of obscure etiology show greater tendency to relapse than forms whose cause is better known. They almost invariably show descemetitis. 3. The fundal changes of so-called "choroidal hyperemia," especially if accompanied by defective accommodation and vitreous opacities, demand guarded prognosis and repeated examination for dim field areas.

842 Park Avenue.

(The symposium on uveitis will be continued by the papers of Drs. Friedenwald, Hansell, Wilder, Woodruff and Marple and the discussion.)

REMARKS ON THE METHODS OF OPERATIONS IN VOGUE FOR CYSTOCELE WITH AND WITHOUT PROLAPSE OF THE UTERUS.*

C. O. THIENHAUS, M.D.
MILWAUKEE, WIS.

When I again take the liberty of bringing the subject of operative treatment of cystocele and prolapse of the uterus, already threshed over in many gynecological societies, before this scientific body. it is not my intention to add to the large supply of methods in vogue a new procedure, substantiated perhaps by two or three operations. but to point out a few thoughts which I believe to be altogether timely.

There has been and still seems to be a great difference of opinion in regard to the question whether retroversion or retroversio-flexion of the uterus, so often connected with cystocele, is the antecedent and primary cause of the cystocele and prolapse or whether, as H. W. Freund[1] expresses himself in his article, "Ueber Moderne Prolapse-operationen," "The descent of the anterior vaginal wall is usually primary. as shown by the extended observation of puerperal cases." There is, in my opinion, hardly a doubt that both opinions find their analogies and that four possibilities of origin of prolapse of the anterior vaginal wall and uterus have to be taken into consideration:

First.—The descensus of the anterior vaginal wall is the primary event in the evolution of prolapse. This class is chiefly produced by sub-involution of the anterior vaginal wall during frequent previous births or attenuation during the climacterium, and we may find sometimes a large cystocele while the uterus shows probably elongation of the cervical part but lies in normal anteversio-flexion.

Second.—A retroflexion, or in most of the cases a retroversion is the causative agent of the prolapse and cystocele. I am absolutely of the opinion that in most of all the cases the mechanism of prolapse occurs in this manner.

Third.—In very few cases an excessive hypertrophy of the vaginal portion of the cervix may be the introducing medium of prolapse. This hypertrophy, which is oftentimes the cause of sterility in young women and the cause of prolapse in virgins and nullipari (Beyea[2] collected recently 64 cases of this kind), has nothing to do with the hypertrophied cervix in the prolapsed womb. This latter hypertrophy, which we find in most every case of prolapse of long standing and which is not the cause but the sequel of the prolapse, is nothing but an edema, and disappears almost entirely after reposition of the prolapse and rest in bed.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

Fourth.—Intra-abdominal tumors and ascites may be the cause of prolapse.

Before I go into details of operative procedures I would like to remind you of one fact which is essential, in my opinion, that is, that the bladder is connected with the cervical portion of the uterus by tense, not by loose connective tissue, as the anatomist Pansch stated at one time. This implies that in every case of prolapse of the cervix, that part of the bladder which is in connection with it must prolapse also. The bladder therefore must change its ball-like form and elongation and diverticulum formation must take place. The complete removal of this diverticulum and restoration of the bladder to a complete ball-like organ, as first advocated by Stone,[3] must naturally be one of the principal factors of every cystocele operation. So long as the bladder is not entirely free from the elongated and prolapsed cervix and the descended anterior vaginal wall, and all strings of connective tissue are not entirely removed, a recurrence of the cystocele is most likely to follow. But even when this is fully accomplished and the bladder is pushed up and disappears like a small ball behind the symphysis, a simple anterior colporrhaphy performed after one of the methods in use with or without amputation of the cervix, is not sufficient to withstand frequent abdominal pressure together with overfilling of the bladder. The scar tissue and the anterior vaginal wall which is, as we know, usually attenuated at the climacteric age will stretch and thereby pave the way for recurrence. To avoid this and to give the bladder a more solid support the idea to employ the muscular wall of the uterus as a pelote, as Kreutzmann[4] and others express it, seems advisable, and this method, in a manner described by Duehrssen, has been used by the writer in every case of cystocele with and without prolapse of the uterus, with excellent results. In women near or about the climacterium the entire anterior uterine wall is fixed to the vaginal wall after anterior colporrhaphy or dissection of flaps from the anterior vaginal wall and opening of the plica vesico-uterina. In younger women where such a fixation would cause disturbances during future pregnancies, the plica vesico-uterina is opened by a sagittal incision and the uterus fixed immediately beneath the origin of the tubes to the anterior vaginal wall by one silkworm-gut stitch, followed with isolated closure of the plica vesico-uterina in a manner described by Duehrssen,[5] or after the method of Mackenrodt,[6] Martin,[7] Ruehl: one and one-half to two centimeters over the internal os, by three catgut sutures.

In all cases in which one finds it necessary, and this necessity arises, in my opinion, in four-fifths of all cases, I add a posterior colpoperineorrhaphy with buried catgut sutures in layers, either after Emmet or Howard Kelly's modification, or Hegar Simon or Martin, etc., according to the alterations found on the posterior vaginal wall and perineum.

It is not my intention to point out at this place again the great advantages which a vaginal celiotomy as compared to abdominal laparotomies has in general for the patient; but not always for the operator: advantages which make it advisable to perform everything which can be performed with safety for the patient, by the vaginal route. These advantages which I have pointed out in my monograph[8] (the retroversio-flexio uteri mobilis et fixata), its conservative and operative treatment, are so uniformly recognized, that they are beyond discussion, and Duehrssen, Martin and many others have shown by their statistics what can be achieved by patience and perseverance in this line of work. Duehrssen[9] divides his vaginal anterior celiotomies in two series of cases, in the first one, 500 vaginal anterior celiotomies, most of them with difficult conservative and radical work on the adnexa and uterus, myomectomies, ovariotomies, etc., he had 3 per cent. mortality, and in his second series, under 428 operations, 2 per cent. In all his cases operated on for retroflexion by his method he had but 2 per cent. recurrences.

Fig 1.—Case 2. Total prolapse of uterus before operation.

Furthermore he states[10] that he removed 36 ruptured extra-uterine pregnancies from five weeks up to the third month, by anterior vaginal celiotomy with no death, and advocates this route for every ruptured extra-uterine pregnancy up to the third month. Strassmann cites at the same place eight extra-uterine pregnancies operated on by the vaginal route, and Martin[11] from 12 cases 9 operated by colpotomia anterior without mortality. I think these results equal those gained by abdominal laparotomies without subjecting the patients to the inconveniences of possible sequelæ of abdominal section. Scanzoni, Jr.,[10] has shown by statistics as cited by Strassmann, that in cases of ruptured extra-uterine pregnancy the results gained by vaginal celiotomy excel those obtained by laparotomy to a large extent. These are but a few facts which show the possibilities of achievement of anterior vaginal celiotomy in the hands of expert surgeons. Naturally, if anywhere, experience and skill is needed for surgical work in the limited field of the vagina.

I must apologize for having asked your indulgence for this aberration, but I may be allowed to add a few remarks concerning what one has pointed out as one of the greatest drawbacks of vaginal fixation, I mean disturbances during future pregnancies. It is true that during the development of these methods because of faulty suggestions, *id est*, to fix the fundus of the uterus directly to the vaginal wall without isolated closure of the plica vesico-uterina, thereby causing tense sero-fibrous adhesions, the development of the uterus during the pregnant state was impaired, and even Cesarean sections were necessary to overcome the difficulties during child bearing. Pape[12] has collected 9 Cesarean sections because of vaginal fixation with 4 deaths. Berndt[13] has added one case later; Duehrssen[14] explains himself thus concerning his vaginal suspension method: "I would like to know one case operated by myself after 1895, in which year I introduced vaginal fixation with isolated closure of the plica vesico-uterina, in which disturbance during future pregnancy has occurred. So long as one is unable to do this I take the liberty of calling all these warnings against vaginal fixation because of danger in future pregnancies unreasonable phrases for which one can hardly find any longer the excuse, ignorance of up-to-date literature." Rieck[15] reviews 1,000 cases of anterior vaginal celiotomy and fixation performed in Martin's Hospital in Berlin and Greifswald from 1892 to 1900.

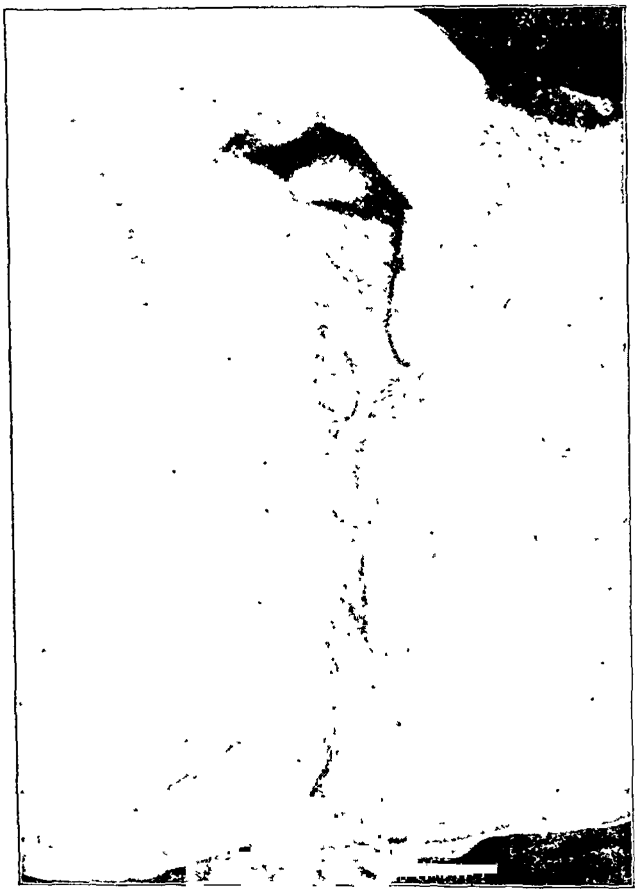

Fig. 2.—Result of operation in Case 2. Taken six months after operation, patient using full force of abdominal pressure.

Up to 1897 Martin fixed the fundus of the uterus to the vagina; of these cases he observed 20 births, in 15 the birth was prolonged but without sequels, in 5 he had to deal with severe disturbances, under these 1 Cesarean section with death. From 1896 to 1900 Martin fixed the uterus not higher than two centimeters over the internal os to the vagina. From this class he observed 10 births without disturbances. Under these 1,000 operations, oftentimes very complicated by adhesions and tumors of the adnexa, he had but 15 deaths; that is, 1.5 per cent.

It is not my intention to state here my experiences and results of vaginal fixation, because the time elapsed since the fixations were performed in Milwaukee is still too short. It suffices to say by the way of anticipation that I have never lost a patient operated on by this method, nor have I heard of a recurrence; two of them are pregnant now.

Returning after this aberration to the prolapse operations, surgeons have in many cases after correcting the malformations in the vagina by amputation of the cervix, anterior colporrhaphy and colpoperineorrhaphy, resorted to abdominal fixations of the womb. A fixation of the uterus will always be necessary, if one resorts to abdominal section, as a suspension, that is, the forming of a ligamentum uteri artificiale suspensorium, will hardly hinder a later descensus of the prolapsed womb, and therewith a recurrence. It must be taken into consideration, however, in performing ventrofixations that, first, the uterus does not usually belong in the abdominal cavity, but in the pelvis; second, that when the adhesions are too tense, disturbances during future pregnancies may ensue just as well as in faulty fixations of the uterus to the vagina (nine cases of Cesarean section because of ventrofixation are cited by Ruehl[16]), and third, that abdominal hernias are apt to occur even if the wound heals by primary intention and is sutured in three separate layers (so-called three Etagennaht). Winter and Olshausen have shown in their statistics that if sutured in separate layers 8 per cent. of hernias follow; in using through-and-through sutures this percentage rises* to 20 per cent. and 30 per cent. Chiefly is this the case when further pregnancies occur, one example of which came to my notice recently. I performed a ventrofixation on a woman after the method of Czerny Leopold four years ago. The wound healed by primary intention, three pregnancies followed afterward without recurrence of the retroflexion, but after the last birth an extensive abdominal hernia developed. A fortnight ago another case came to my notice which was operated on by a surgeon in Milwaukee for prolapse of the womb six months ago. The result is now ventral hernia and recurrence of the prolapse. She has enough of operative procedures and prefers to stay in bed the rest of her life rather than undergo another operation. It is, however, certainly true that in very many cases not the method itself is to blame, but other circumstances and oftentimes, unfortunately, the performer himself. It must be admitted that some surgeons have had excellent results after this method. Noble,[17] for instance, cites 130 cases of procidentia uteri operated on accordingly with excellent results.

Some surgeons expect to overcome the prolapse of the uterus by vaginal total extirpation of the organ itself. In doing this one digs, in my opinion, one's own grave and opens all possibilities for future recurrence. The scar tissue which is left can never be so strong a wall against the descensus of the bladder and the abdominal pressure as the muscular wall of the uterus when used as a pelote and fixed in a proper manner as described above. Only when the total extirpation of the uterus is followed by resection of the greater part of the anterior and posterior vaginal wall or of the total vagina, more satisfactory results have been obtained. Wertheim,[18] Vienna, goes still a step farther than Duehrssen in his method. After anterior vaginal celiotomy he takes the uterus into the vagina and sutures the flaps of the anterior vaginal wall to the posterior wall of the uterus. This method, reserved naturally for cases after the menopause or for cases in which at the same time a resection of the tubes makes further pregnancies impossible, seems rational. Brettauer[19] used this method in three cases with good results. Bucura[20] cites the results of the originator of this method. 16 cases with 1 recurrence. I have, however, never seen a case in which I found it necessary to use this method or to resort to the method of W. H. Freund or Fritsch,[21] that is, taking the uterus into the vagina and suturing it to the anterior and posterior vaginal wall after resection of flaps of both these walls. After this latter operation cohabitation is naturally impossible and an opening has to be made in the fundus for the menstrual flow and mucous secretion. Von Herff[22] cites that all his seven cases operated on after Freund's method were complete failures.

---

* *Vide* my monograph, Retroversio-flexio Uteri, etc., page 4, Iowa Medical Journal, 1900.

The method of introducing one or two wires in the submucosa of the vagina, thereby checking the descensus of the womb, or Mueller's method, to close the vagina entirely, thereby sinking the uterus in the depths, are hardly any more warranted, in my opinion, at our time of perfect technic of other more reliable methods. Gersuny's[23] ingenious idea of injecting paraffin into the submucosa in cases of cystocele as a support for the bladder has still to stand the test of time, and Pfannenstiel[24] cites a case of paraffin embolism.

I may be allowed to make a few remarks about the question of cuneiform excision or infra-vaginal amputation of the cervix as an essential part of prolapse operations. Where so-called erosion ulcers are encountered or a hypertrophy of large degree is present, an amputation is advisable, not only because of these reasons, but because every amputation of the cervix has a marked effect on the hypertrophy of the uterus as well. In many cases, however, the so-called collum edema disappears entirely after the correction of the position of the uterus by fixation to the anterior vaginal wall.

The operation as I have performed it up to date is as follows:

First.—Curettement and cuneiform excision of both cervical lips, or infra-vaginal amputation of the cervix if necessary.

Second.—Anterior colporrhaphy in an oval, or better, triangular form, or by the dissecting of two flaps after an ⊥-shaped incision.

Third.—Thorough freeing of the bladder from the cervix, the anterior vaginal wall, the parametria and the plica vesico-uterina, pushing up of the bladder, which now again has the form of a ball, and folding of the organ by layers of purse-string sutures if necessary.

Fourth.—Opening of the plica vesico-uterina by sagittal incision and suturing of the entire uterine wall to the vagina by four or five catgut stitches and two silkworm-gut stitches in a woman near the climacterium or after the menopause. In younger women a silkworm-gut stitch is passed through the vagina, plica and uterus a little beneath the fundus and plica and vagina on the other side (vaginal suspension), which remains there for six weeks. After this the sagittal incision through the plica vesico-uterina is closed separately by a continuous catgut suture (Duehrssen's method). Or the plica is opened in a transverse direction and not higher than from 1.5 to 2 centimeters over the internal os, sutured separately by a catgut suture to the anterior wall of the uterus. The same suture passes on both sides through the vaginal wall. Immediately under this suture two other catgut sutures are passed through the vaginal wall, uterus and vaginal wall on the other side, after Martin's method.

Fifth.—Posterior colpoperineorrhaphy following one of the above methods with buried catgut sutures as advocated first by Werth.*

At the close of my paper I would like to point out that it is not my intention to demonstrate that the method advocated is the method and the only method. There are many phases of prolapse of the uterus and cystocele for which one or the other methods has shown good results in the hands of expert and thorough surgeons, and he is doubtless the best surgeon who knows all methods and selects in the individual case that method which cures the patient.

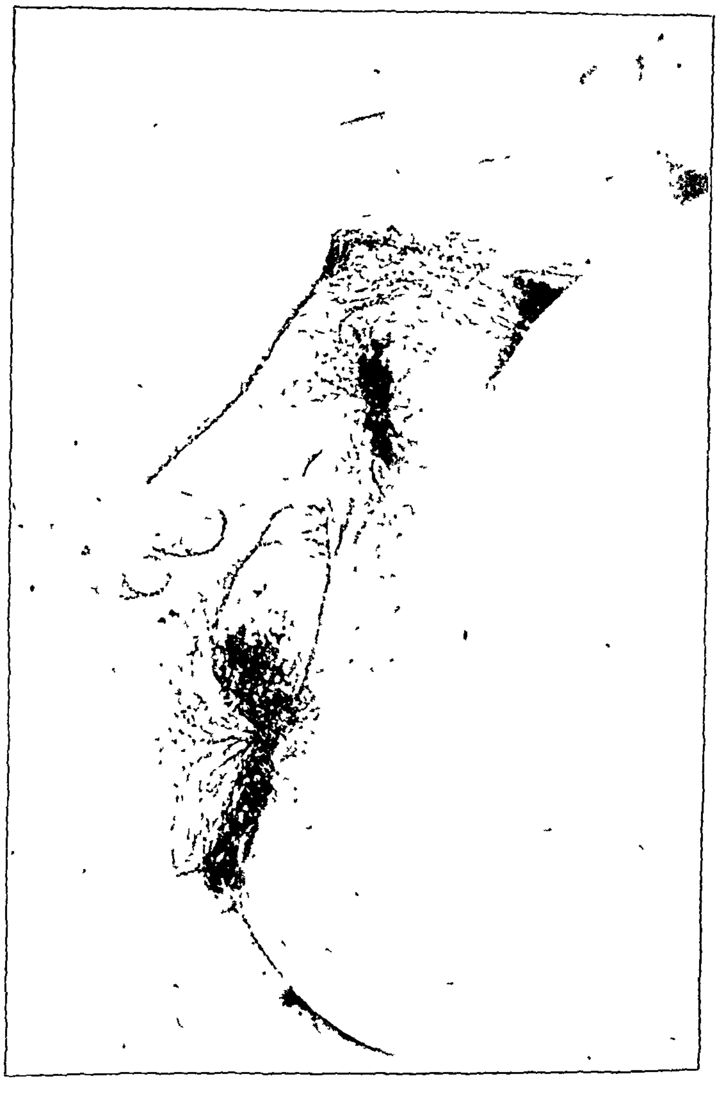

Fig. 3.—Case 3. Total prolapse of the uterus and irreducible umbilical hernia.

I will be amply satisfied if this topic and the method advocated has aroused your interest and seems worthy of your future consideration and trial, because I am fully convinced, after my own experience, of the truthful words of Fritsch.[25] I can assert that, provided the correct technic is used, one is doubtless enabled to cure every prolapse by the vaginal route.

The following three cases of total prolapse of the uterus (I omit the operations for cystocele) on which I had the opportunity of operating in the last two years in Milwaukee after Duehrssen's method, may illustrate my contention.

---

* Vide Operative Gynecology, Kelly.

CASE 1.—Mrs. P., 53 years of age, had suffered for ten years from descensus of her bladder and uterus. Since five years ago the entire womb has lain outside of the vagina and after several efforts to get relief from supporters of different kinds she has been for three years unable to perform any house work and was confined to her bed most of the time. Operation after Duehrssen's method two years ago. She left the hospital four weeks after the operation with a perfect result and is enabled to do any required work. No signs of recurrence whatsoever.

CASE 2.—Mrs. H., 67 years of age, was suffering from prolapse of the uterus (Fig. 1) for 12 years and confined to her bed most of the time in the last three years. Operation six months ago; left the hospital four and a half weeks after operation with perfect result and is enabled to fulfill all her household duties. Fig. 2, taken six months after operation, shows the result, the patient being instructed to use the full force of abdominal pressure. A part of the bulbous urethræ, which for good reasons I did not remove, can be seen in the vaginal outlet.

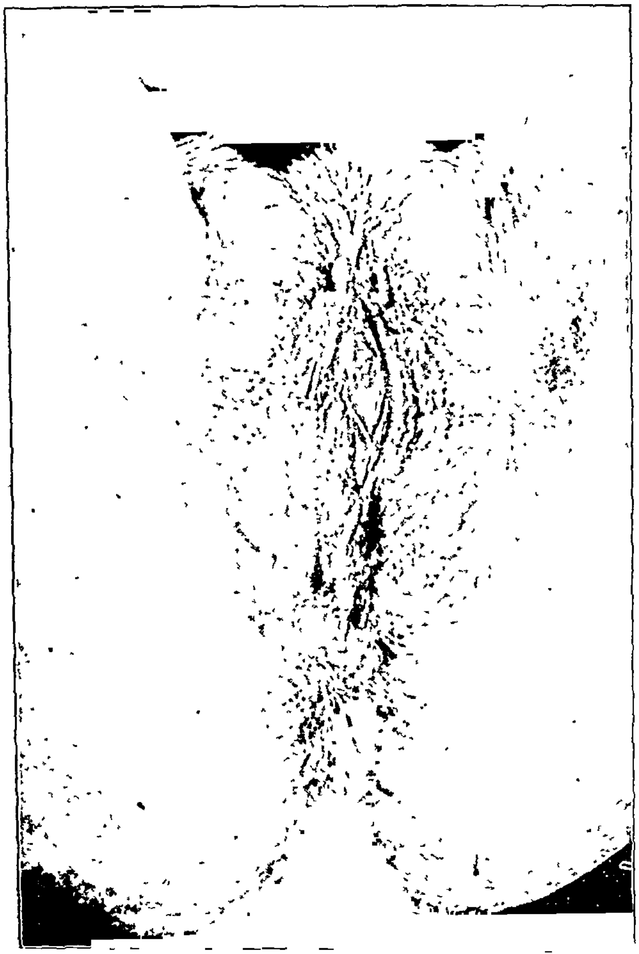

Fig 4.—Result of operation in Case 3. One and one-half months after operation, the patient using full abdominal pressure. The white line on the perineum indicates the scar.

CASE 3.—Mrs. D., 63 years of age, was suffering from an umbilical hernia containing adherent omentum for 23 years and a total prolapse of the womb for 11 years (Fig. 3). Operation three weeks ago. The wounds are healed by primary intention and she will leave the hospital in the coming week. Fig. 4 shows the result.

Case 1 has stood the test of time and the result is ideal. Cases 2 and 3 are perfect up to date, but not enough time has elapsed to form definite conclusions.

Post-Graduate Hospital.

DISCUSSION.

DR. W. F. METCALF, Detroit—I have had no experience with the fixation of the uterus in the anterior vaginal wall. It seems as though the circulation in the uterus would be disturbed by fixing it thus in unnatural position. The cases that have come under my care I have handled very satisfactorily. If there be great hypertrophy with much scar tissue in the cervix, the woman having reached the menopause, I perform vaginal hysterectomy, sew the ends of the broad ligaments together, perform anterior colporrhaphy, and repair the perineum. Where the pathologic changes in the uterus and adnexa can be corrected I prefer to repair the vaginal outlet as perfectly as possible and do ventro-suspension. As the nutrition of the individual improves the tone of the ligaments is restored and the organ is held in position, with little likelihood of again becoming displaced even when pregnancy supervenes.

DR. H. D. INGRAHAM, Buffalo, N. Y.—This is a very ingenious plan, but I am afraid not a very good one, as it creates an abnormal condition by putting the uterus where it was not intended to be. It seems to me that there is hardly room for it below the bladder. In a woman advanced in years the parts are atrophied, and not much room is left. In my experience prolapse of the uterus is one of the worst conditions we have to deal with. I have tried almost every plan except this one, and in spite of all that I can do, the uterus usually comes down after awhile. One of the worst things to do is a hysterectomy, as it leaves the woman in worse condition than before. We can all put the uterus in good condition for a few months, but in two or three years afterwards the patient's condition is not so good. I used the purse-string suture for cystocele, but found it sometimes made the patient worse. If there is any plan to put the uterus up and keep it there, I shall be glad to know what it is. Repairing the perineum and closing up the vagina as much as possible is good. I did an operation years ago which promised well, that is, putting in two or three silver wire sutures and leaving them, and making the vagina smaller. The uterus could not come down, but after a while gangrene of the uterus occurred, and I had to remove the organ. If I get a suitable case, I am going to try the operation of the essayist.

DR. GEORGE M. BOYD, Philadelphia—I am inclined to agree with the last speaker, because of the fact that I believe that prolapse of the uterus, bladder and rectum should be looked on as a hernia and treated accordingly. Removing the uterus does not cure the hernia. My method is to first determine the size of the uterus. In a certain proportion of cases it seems to be materially enlarged. A great point in the operation is the reduction in weight of the uterus by careful amputation of the cervix. Next perform an anterior colporrhaphy and then repair the perineum. At a second operation I suspend the uterus. My results have been very good. I allow the patient to rest three weeks before doing the second operation. I could hardly countenance doing a hysterectomy without repairing the pelvic floor.

Dr. C. L. Bonifield, Cincinnati—In the remarks made credit has not been given to an American operator to whom it is due. Dr. I. S. Stone, Washington, D. C., originated the idea of lifting the bladder up and attaching it to the uterus at a higher level. He proposed this method in a paper before the Cincinnati Academy of Medicine two or three years ago and he is entitled to priority in the principle involved. Dr. Stone also recommended, although this was not original with him, that after the bladder had been lifted up and attached to the uterus higher than before, that the uterus be fixed to the abdominal wall. This is one of the best operations that can be done for bad degrees of prolapse. I think the operation that Dr. Thienhaus speaks of, turning the uterus in the vagina, and stitching the vaginal wall to the posterior wall of the uterus, should be mentioned only to be condemned. It does not appeal to reason.

I agree with Dr. Boyd in almost everything he said. Prolapse of the uterus and posterior vaginal wall are to be regarded as a kind of hernia. These things are particularly apt to occur after a woman has had several children and her health has been much reduced, and when the subcutaneous fat is being absorbed. This is also true of hernia. I have known men, as well as women, who, when they were run down from any cause, had an inguinal or femoral hernia. When the general health was improved, the hernia disappeared, without operation or truss. With advancing years the hernia reappeared, proving that the general tone of the system has a good deal to do with it. The real cause of prolapse is disproportion between the strength of the supports of the uterus and the weight of this organ itself.

If you weaken the supports, you are bound to have a prolapse, as they can not hold the uterus in place and the first step in a prolapse is retroversion. The cause of weakening the supports is absorption of the subcutaneous fat, relaxation due to frequent pregnancies or poor health. Dr. Goffe said that the uterus was held in position by the ligaments. That probably was true when we went on all fours. If you look at the uterus as an organ to be held in place by ligaments, you can see that these ligaments would answer admirably if we were quadrupeds, but they do not hold the uterus in position now, when we are bipeds. Intra-abdominal pressure is one of the most important factors in holding the uterus in place, and we can not have this unless there is a certain amount of tone to the abdominal wall.

If weakened supports and increased weight of the uterus are the causes of prolapse, the indications for treatment are to diminish the weight of the uterus and increase the strength and, if necessary, add to the number of the supports. The weight of the uterus can be diminished by rest in bed, tampons, curettage and amputation of the cervix. The strength of the supports can be increased by tonics, exercise and massage. Ventrosuspension or fixation gives the uterus an additional support of value. Ventrofixation should not be done in a patient that is liable to become pregnant, but there is not the same objection to doing a ventrosuspension. No matter by what method a woman who has suffered from an extreme degree of prolapse has been cured, she should not permit herself to become pregnant.

Dr. Thienhaus mentioned a European operator that has 8 per cent. of hernias following abdominal section. I should feel very much chagrined if my abdominal sections were followed by that percentage of hernias. The best operators in this country, men who close the abdominal wall with due care and pay especial attention to the after care of patients, secure better results than those quoted.

I agree with Drs. Boyd and Ingraham that the uterus should never be removed in these cases. I have never done it, and never will, but I have had a number of patients come to me where someone else had removed the uterus and the last condition was worse than the first. Dr. Thienhaus pointed out that his operation is not applicable to cases that are liable to become pregnant.

Dr. Edwin Ricketts, Cincinnati—I heard the paper read by Dr. Stone at Cincinnati, and it affords me great pleasure to bear out what Dr. Bonifield has said in regard to it. If you have not already looked up the operation suggested by Dr. Stone, you will find it of great interest to do so. As has been said, these cases should be classified, and in all those cases where abdominal fixation is done, the patient should never be permitted to become pregnant afterwards. In abdominal fixation another thing must be taken into consideration, and that is the condition of the perineum. No matter what you do, your efforts will be futile if you do not repair a lacerated perineum. High amputation is a thing that must be considered in some cases if we wish to obtain the best results. There are things that go hand in hand, and we must always be careful to exercise our best judgment in determining what is best to do for these cases of prolapse.

Dr. Thienhaus, in closing—I have not much to add to what I have already said in my paper, and if I have succeeded in arousing your interest in the subject I shall feel myself well repaid. Dr. Metcalf will find that in many of the cases of prolapse of the uterus, in which a vaginal hysterectomy has been performed, a hernia develops later on. When we have to deal with an umbilical hernia of larger size we split the sheath of the rectus muscle and make use of this muscle in one way or the other. In the same manner we can make use of the muscular wall of the uterus in cases of prolapse and this principle I have advocated in my operation.

SURGICAL TREATMENT OF HEMORRHOIDS.*

WM. F. METCALF, M.D.
DETROIT.

I bring this subject before the Section on Diseases of Women because hemorrhoids so frequently accompany pathologic changes in the uterus and its adnexa. The gynecologist who does not treat the rectum can not get the best results.

From the time of Samuel, when, as is recorded, the men of Ashdod, Gaza, Askelon, Gath and Ekron had emerods in their secret parts, and I know not how long before this period, the treatment of hemorrhoids has been of interest. In those ancient times the priests instructed the Phillistines to prepare five golden images of the emerods which "mar the land," place them in the ark of the Lord and return them as a trespass offering to the Israelites, from whom they had taken it. This they did and were accordingly healed. The same act on the part of the laity prevails to-day, with this difference, the golden images are given to the surgeon, or more often to the quack specialist instead of to the priest. Last year, while visiting southern Mexico, I found some of the inhabitants there carrying a species of native bean in their pockets, believing that so long as they did so they would not be troubled with piles.

We will pass from these faith cures to treatment based upon the thought of their being material entities of only local significance. This thought produced methods of treatment in which the comfort of the patient and the welfare of the organism received little or no consideration, and some of these methods are in use to-day. The thought governing the best treatment lies midway between these extremes.

I believe that to the presence of internal hemorrhoids is due many of those reflex phenomena frequently ascribed to pathologic changes in the organs of generation. Arguments to substantiate this statement are to you, gentlemen, unnecessary, and I will pass them by with a few observations. I have seen tic of the orbicularis palpebrarum muscle of twenty years' standing disappear immediately upon the removal of internal hemorrhoids; long-continued pain in the epigastric region disappears within a week not to return; sciatica cured;

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. H. Cordier, W. E. B. Davis and Henry P. Newman.

intestinal fermentation attended with constipation or diarrhea disappear; improvement in the circulation; a desquamation of the cuticle; improvement in hearing; relief of hyperemia; improvement in digestion and nutrition, and numerous other manifestations which compel my recognition of internal hemorrhoids as a possible cause of numerous systemic disturbances. Any or all of these phenomena are occasionally observed following correction of pathologic changes in the uterus and its adnexa.

External inflamed hemorrhoids which produce local discomfort are productive of less disturbance in distant parts of the body than is caused by internal hemorrhoids of which the patient has no thought.

When possible, operation on the rectum should be done at the same time as operations on the genital organs. A method should, however, be used which leaves less immediate irritation than the system has been subject to from the condition which attempt is made to correct. Thorough dilation of the sphincters should accompany any traumatism within their grasp. The result is to cause dilation of all capillaries and thus to relieve local congestions by equalizing the circulation. This insures better results, both immediate and remote, in operations on other parts.

The thought of prevention of hemorrhoids and of the permanence of cure compels a consideration of their causes. According to David's report in the LXXVIII Psalm, God smote His enemies in the hinder parts because of their high living. Intemperance and worry are still recognized as potent factors in their causation. We may add to the anatomic causes which are recognized as chief, inherited tendency to weak vein walls; undue straining at stool, which, in some cases, is necessitated because of disease of the rectal valves, as pointed out by Dr. Martin of Cleveland; morbid growths or pathologic changes which obstruct the veins of the portal system; any disease in any part of the body which disturbs the equilibrium of the circulation; or any irritation which reflexly disturbs the peristalsis of the intestine or the quality or quantity of the digestive secretion. Thus in the preventive treatment of hemorrhoids the gynecologist plays an important rôle.

The question of contra-indications to operation upon hemorrhoids commands a much less serious consideration when we recognize that practically no danger attends such operations. The life of a patient who has had or is having a condition of more or less definite portal obstruction, may, in many cases, be made more endurable even if we do not, as I believe, vastly improve the prospect for a substantial gain in general condition. And of no class of cases is this more true than of those which come under the eye of the gynecologist.

The method of treatment which I shall endeavor to present for consideration is based upon an experience of more than seven hundred cases operated upon during the last ten years. You are all undoubtedly familiar with the methods advocated by Mathews, Ball, Alling- am and Gant.

Of the method by ligature Matthews says: "Scarcely as there ever been such a consensus of opinion among oted surgeons in regard to the surgical treatment of ny disease as of internal hemorrhoids." All the au- horities to which he refers agreeing that the ligature the "simplest and most radical cure for internal emorrhoids." Ligature *en masse* is meant. In this onnection Mathews says: "It is important to use two zes of thread—a small size for the small tumors and a larger size for the larger tumors." Further he says: "I think a stout linen thread quite as good as silk, but it must be understood that it must be so stout that it will not break with the hardest pulling. Much confusion arises, especially after transfixing a tumor, from having the thread break. It is best, also, to have it well waxed, for the reason that it adds somewhat to its strength, but mainly because it makes the knot more secure." I will not quote further, as you are all familiar with the method. He raises the question as to how much of the pile should be cut off above the ligature, with reference to which he says: "I think the advice usually given by authors is a little too careful, for this reason, if we only clip off a little portion of the tumor we leave the major portions to be pushed back into the bowel, consequently that much more tissue is left to slough." Further, he says: "I am in the habit of cutting off two-thirds." Thus one-third of the tumor above the ligature, we should observe, is replaced to slough. In this connection Ball of Dublin says in substances: "Ligatures, or sloughs following crushing and the use of the cautery, come away about the end of the first week. There remain, however, ulcerated surfaces which require about another week to heal. During this period it is better for the patient to remain in bed because the rectal veins have no valves, which condition may prevent healing."

Does not the surgical principle of avoidance of tissue strangulation apply to this as to other parts of the body? There is a better method. Internal piles are tumors formed by dilated vein extremities embedded in exudate, the result of congestion, and lying wholly or in part above the external sphincter. This exudate in time becomes fibrous. The arterial supply of these tumors is from above, the vessels extending parallel with the gut. The tendency of these arteries when cut is to retract within the loose tissue above the tumor. The vein extremities can be cut without danger of hemorrhage. I am now speaking of uncomplicated internal hemorrhoids, which I believe always arise between the sphincters. In some cases they do extend above the internal sphincter, in dealing with which the danger of hemorrhage is greater and ligation of arteries is occasionally necessary.

Allingham[1] describes his method of excision as follows: "In performing excision I first gently but fully dilate the sphincter muscle and employ a retractor to keep the anus well open. I then seize the pile deeply by the base, cut it off below the level of the vulcellum, and do not let it go till all the bleeding is arrested by torsion of the arteries. Rarely more than two vessels spout and require twisting. I wait for a little while to see that all bleeding has ceased, and then I treat the other piles in the same manner." Mathews says of this method: "I think that those who have done much operating around the rectum will bear me out in saying that in but few hands could this operation be regarded as a safe one, and can never become popular." I do not agree with Dr. Mathew's prediction, and would add to Dr. Allingham's description that in many cases even torsion of the arteries is not required.

In my opinion uncomplicated internal hemorrhoids should be treated in the following manner: The comfort of the patient is dependent on the closest attention to detail. Two or three days before operation a physic should be given. A gentle physic should be given the day preceding operation, a high enema the night before, and an ordinary enema the morning of operation. The patient is fully anesthetized and placed in the dorsal position, the legs being held by a Clover crutch. I prefer the dorsal position because in the majority of cases genito-urinary work is required, and should ordinarily be done before the rectum is touched. I prefer to clip off the hair with the scissors. If parts are shaved great discomfort attends its outgrowing at a certain stage. The most satisfactory speculum that I have found is known as the Pratt bivalve. After adjusting the speculum so that a pile tumor presents between the separated blades, I take hold of the margin of the mucous membrane below the tumor, and with the sharp-pointed scissors curved upon the flap I strip off the membrane covering the vein extremities, which often present the appearance of grapes and should be clipped off with scissors. If there be but a small quantity of fibrous tissue, this is all that is necessary; the tumor will have disappeared. If there be much fibrous tissue, I cut it off smoothly from the surface of the muscle. If a spurting vessel presents I pick it up with a pair of artery forceps and proceed to deal in the same manner with the next tumor. (The largest arteries are found, one anterior and one upon each side near the center.) When I have thus passed around the whole circumference I remove the artery forceps. I then dilate the sphincters gently but thoroughly and examine for bleeding points, which if found are again picked up with fine-pointed artery forceps and ligated with fine catgut, placed through the tissue as a stitch that it may not slip off. The thorough divulsion is a potent factor in the lessening of the venous hemorrhage. This ligation is seldom necessary, as the artery, freed from the fibrous tissue, retracts, and its intima being wounded by the forceps, its lumen is closed. If irritable tags of redundant skin about the margin of the anus have to be removed, leaving a considerable surface denuded, the skin edges should be approximated by suture to lessen the formation of cicatrix. A plug of gauze dusted with antiseptic powder should then be inserted. This plug lessens capillary hemorrhage. It should be removed as soon as the patient complains of pain, but before consciousness is gained. Its removal clears away any small clots which may have formed. Sterile gauze wrung out of water as hot as can be borne is at once pressed firmly against the anus. This is repeated by the nurse every few minutes until the patient is comfortable, when a larger compress should be firmly secured by a T-bandage. This gentle but firm pressure lessens the tendency to spasm.

---

[1] Mathews: "Diseases of Rectum," p. 149.

If the patient be a woman morphin is seldom required—in fact, many will never know that the rectum has been operated on when it is done in connection with other operations. In men there is usually a greater tendency to spasm of the sphincter muscles, and an anodyne often has to be given.

It will be seen that this method leaves strips of mucous membrane longitudinal to the gut and attached to the skin margin and to the membrane above. This makes subsequent stricture impossible, and from these strips of membrane new will develop to cover the entire circumference in about a week. Such surface can be more easily kept clean and has greater power to resist infection than has a tissue crushed to the point of sloughing by ligature. After the first day comfort and cleanliness are insured by letting a stream of some antiseptic solution play upon the parts, the patient being placed upon the side upon a rubber pad and instructed to strain down. Water need not be thrown within the sphincters. In fact, I think it better not to pass anything into the rectum until healing is well-nigh complete, unless colic is troublesome, which may and should be relieved by the passage of a sterilized rectal tube. The wounded surfaces usually induce constipation until a stool is forced, which should be done about the fifth day, by which time if there has been no infection the surface is covered with epithelium.

In discussing the question of scar formation, the principles of general surgery should hold here as elsewhere, that the relative approach to asepsis will induce a consequently less marked degree of inflammatory reaction, small-celled infiltration and formation of new connective tissue. The closing in of the epithelial structures from both the columnar above and the squamous below is prompt and is evident microscopically, as I have repeatedly demonstrated in dogs, as well as in a case who died a month after operation. In this case the operation was combined with others and the result could not be traced to any relation with the rectal operation since healing had proceeded as usual by what was practically first intention.

Dr. Henneage Gibbs, pathologist of the Detroit Clinical Laboratory, reports as follows, after examination of the rectal mucus membrane taken from a dog five days after operation: "Result of examinations of sections through the whole affected part in three series by differential staining shows the part from which the mucous membrane was removed to be covered by a layer of squamous epithelium derived from and continuous with the healthy tissue. The new covering is only two cells in thickness, but it has covered the exposed part without the formation of pus, and is, therefore, a healing by first intention."

In comparing the healing process beneath this mucous membrane, with that beneath a new-formed skin the same essential features are observed. The conditions presented when proper precautions are taken before the operation are such that the irritation of the surface is reduced to a minimum. I believe the serum thrown out by the denuded surface the ideal protective after the first slight hemorrhage is checked. Again, the conditions after operation are here much more favorable than in the skin. The underlying muscular structures serve to protect the area denuded and are less subject to inflammatory reaction than the subcutaneous tissue, and when the repair process is under way and the actual contraction of the new-formed connective tissue, which is small in quantity compared with that found in skin, tends to take place, there is instituted a regular and frequent dilatation of the bowel by the passage of its contents.

In certain cases the whole circumference of the rectum is diseased and prolapses. In these cases I think amputation of the redundant membrane advisable. The success of this operation, as much as of any other, depends upon the careful attention to detail. The first step is a thorough dilatation of the sphincters. The diseased membrane is then pulled down around the whole circumference and held with T-forceps, six pairs being required. With one finger upon the external sphincter to guide the point of the scissors, which is entered above the grasp of the forceps, the entire circumference is amputated. The arteries in the membrane above are caught with hemostatic forceps as they are cut. The pile tumors cling to the membrane removed. The external sphincter is now wholly and clearly exposed, and if there be any break in its fibers it can be restored by bringing their ends together with fine catgut suture. We now have the diseased membrane, to the upper edge of which the T-forceps are attached, hanging outside the anus and attached to the skin margin. This separation may be made first, the dissection being carried from below upward. If too much encroachment be made upon the skin a mucous-producing surface will always remain outside the sphincter. If too little is removed the skin margin may be drawn within the grasp of the external sphincter. The membrane which has retracted upward is now pulled down, the longitudinal fibers cut near its margin, and the circular fibers forming the internal sphincter pushed upward, when it is stitched to the margin of the skin. For this I use a continuous suture of catgut passing each time through the loop, as in making buttonholes. The epidermal layer should not be pierced that there may be less tenesmus and discomfort. I usually fortify each quadrant by an independent suture. Aseptic dressing is then applied, and one-quarter grain of morphin is administered. After twenty-four hours the wash should be begun and used two or three times a day, as after the other operation described. It promotes comfort. From one to two weeks subsequent to operation any irritable projections around the anal margin may be smoothed off with the scissors. Two or three times, at intervals of about a month, the sphincters may need to be dilated.

I have found it necessary to do this operation in only about 5 per cent. of the cases operated upon. The result in every case so far as I know has been satisfactory, except in one case, in which there is not as good control of the gas as might be wished. Its cause is probably a break in some of the fibers of the external sphincter at the posterior commissure, which I knew existed at the time, but which I did not think of sufficient importance to repair. In some cases they do not have complete control of the gas for two or three months. I have found this true even in cases where the action of the sphincters appeared normal, and have ascribed it to defective sensation, the gas passing too far down before its presence is recognized.

This is a slight modification of Whitehead's operation, of which the *London Lancet*[1] says: "In the treatment of internal hemorrhoids the authors advocate ligature and tell us that they never employ any other method. Their objection to every one of the clamp methods is on the ground that with the hemorrhoids some healthy mucous membrane must be removed also, while they consider that Whitehead's operation leads to a serious loss of blood, is tardy in healing and is liable to cause ultimate contraction of the lower part of the rectum. All these objections are imaginary and none of these evils result when operations are carefully performed."

Dr. Walter Whitehead[2] of Manchester, in commenting on the above editorial, makes the following, among other statements: "My experience with excision, which now covers a vast number of cases and extends over a period of twenty-five years, has completely convinced me that when the operation is performed as directed and common intelligent principles of general surgery are observed, there is no excessive hemorrhage, and I can absolutely deny that the slightest contraction of the lower bowel ever can or does take place unless some of the skin at the verge of the anus is sacrificed—which would be a distinct violation of the instructions given for the excision. Contraction depends entirely upon the removal of skin, and the contraction bears almost a direct relation to the amount of skin removed."

In my work on the rectum I wish to acknowledge my indebtedness to Drs. Allingham, Mathews, Pratt, Ball, Gross, Quain, Gant and others.

THE CAUSAL RELATION OF BLOOD POVERTY TO GASTRIC ULCER:

WITH REPORT OF AN ILLUSTRATIVE CASE WITH ATYPICAL SYMPTOMS.*

ROBERT N. WILLSON, M.D.
PHILADELPHIA.

As there is perhaps no subject the etiology of which has been so thoroughly thrashed over as that of gastric ulcer, and with so little final satisfaction in the way of a definite conclusion, it may not prove uninteresting to consider the condition with reference to a case that presents strong evidence of an actual causal systemic condition. Although traumatic as well as tubercular and syphilitic ulcers, and similar lesions of the stomach, are infrequent phenomena, when they do occur their etiology is clear because of known existing conditions. The characteristic peptic ulcer, or, as it might be well named, the pyloric ulcer, from its frequent occurrence in this position, gives, however, only a hint as to its causation; and the best writers on the subject satisfy themselves with the statement that in all probability a lesion of the mucous membrane has been present, followed by self-digestion of the gastric wall. In studying the etiology of the pyloric ulcer we have at hand the following undisputed facts gathered from clinical and portmortem observation.

The typical peptic ulcer occurs in about 5 per cent. of all hospital cases (Welch, Bramwell, etc.), and in probably a slightly lower percentage of the general population. Statistics are by no means fair means of arriving at such figures, since few cases are autopsied outside the walls of hospitals, and yet without question many of the general population are carrying unrecognized gastric ulcers into their daily life. On the other hand, hospital subjects show a greater tendency to lesions of all kinds than the general population. Statistics are, however, our only guides to an approximate knowledge of the frequency of the condition. The age at which gastric ulcer most frequently occurs seems at the present time to be between the 16th and 30th years, although Brinton, in his classic monograph (1857), stated that of the cases studied by him the greatest number occurred in the second half of adult life and in old age.

It seems also to be agreed generally that the peptic ulcer occurs in a large percentage of all cases at or near the pylorus, on the posterior wall, and near the lesser curvature. (Mayo Robson's recent statement that latent gastric ulcer is usually found at the lesser curvature near the cardia is not borne out by general experience. He states that such a position easily explains the latency of the lesion, since food is taken in the erect posture and is less likely to irritate the eroded gastric wall at this point. We know, however, from the autopsy table that latent ulcers outnumber the open variety two or three to one; and as Robson himself admits that the greatest number of peptic ulcers are lodged near the pylorus it seems difficult to follow his reasoning in arriving at these contradictory conclusions.) We know, also, that its character is that of a funnel, with the smaller opening toward the serosa and the larger in the mucosa itself, while its base is usually clean and its walls punched out and sharply defined; also, that it usually occurs in single formation, though as many as five are frequently found and thirty-four were noted by Berthhold in a case cited by nearly every writer on the subject. Even when multiple these ulcers have usually been found near the pylorus, and often at points in apposition with one another. It is also generally conceded that the female sex is especially involved, and in many instances the lower classes, including seamstresses and housemaids; also, that associated with the ulcer there is usually, if not always, a marked condition of anemia. Finally, the theory seems to meet with general approval that for one reason or another the mucous membrane of the stomach loses its resisting power to the acids of the gastric juice, and that self-digestion takes place. There is a tendency,[1] especially at the present time, to ascribe gastric ulcer, with every other pathologic condition, to microbic infection, but it seems safe to say that as yet this is not the preponderant opinion. In fact, it seems to be the most difficult one to explain.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

Further than the foregoing we may not venture, and the authorities in considering the features of peptic ulcer lead us further only into conjecture. Just what causes tend to a loss of resistance to the acid gastric juice have never been satisfactorily determined. Arterial and venous thrombosis have been suggested, and undoubtedly do occur, but rarely, and still more seldom in the conditions that are associated with gastric ulcer. Embolism has been a favorite experimental theory, but emboli of the gastric mucosa almost invariably occur at the cardia, while peptic ulcer is much less often found at this point. Moreover, thrombi and emboli have only very rarely been found in the postmortem stomach, and are difficult to cause experimentally. Still further, cardiac disease and other conditions of the circulatory system that tend to the formation of emboli do not furnish a sufficient number of gastric ulcers to form more than an incident in the entire number, though gastric disturbance is frequent in these conditions and almost the rule. Mechanical injuries, contact with corrosive substances, compression (as from tight belts and corsets), microbic infection, have all been suggested, and in isolated instances all undoubtedly play their part, but to no such extent as to account for such a percentage morbidity as one-twentieth of all hospital patients.

As early as 1857, however, Brinton remarked of gastric ulcer that "careful clinical study leaves me . . . . little doubt with respect to the remarkable influence of poverty and intemperance." And Gempt, in 1886, wrote that "it is often necessary to remove the ultimate cause, i. e., the anemia or chlorosis before the healing of a gastric ulcer can be accomplished." In order to bring about this result he gave the albuminate of iron, although other authorities at the time condemned the use of iron at this stage on account of its irritant effect. Gempt did not even look on hematemesis as a contraindication to the use of iron. Osler in his text-book says "anemia and chlorosis predispose strongly to gastric ulcer"; Ewald and Leube both suggest a causal connection between anemia, hyperchlorhydria and gastric ulcer; and finally the case reported in this paper lends evidence of the strongest kind to the theory that the necessary condition of lowered resistance to the digestive action of the gastric juice is best furnished by a gastric poverty of blood—including in the term a lack of one or all of its constituent parts.

Mrs. ——, a physician's wife, 25 years of age, was first seen by the writer in May, 1901, at which time she was pale and chlorotic in appearance, but felt well except for a constant wearied feeling of which she spoke as nothing new in her experience at that time of year. Her blood was examined and showed hemoglobin 55-60 per cent (Fleischl), red corpuscles 4,650,000 and leucocytes 8200; no poikilocytosis; no other pathologic blood changes. She had always been pale but no other blood record had ever been obtained. She was then placed upon a course of iron treatment by her husband, which was followed only irregularly. The patient, however, felt well throughout the summer.

Her father is alive and well. Her mother died of carcinoma of the mamma after a very late fertility (48). Two brothers and one sister of the patient have the same pale, anemic appearance, though presumably to themselves and others, perfectly well. The patient was always well and strong during childhood, and had no serious illness until her sixteenth year, when she went through an attack of typhoid fever, complicated with severe cerebrospinal symptoms. She recovered perfectly, but has had since that time a tender spot over one spinous process (the fourth cervical) that has always been sensitive to the touch and to pressure.

The menses began about the sixteenth year and have been regular; they last over a period of five or six days, and considerable blood is lost. This was also the case with her mother, and is now with a sister who is still living and well. There is some functional pain on the first day, but with the appearance of the flow this disappears. No history of edema or headaches, but a slight tendency to occasional bilious attacks, during which she has suffered from headache, constipation, nausea and sometimes vomiting, and then again has felt perfectly well. Often with these bilious attacks there was nosebleed, though the latter has not occurred for more than a year. Never any bleeding from the bowel or stomach. Patient has always craved sour things, and especially during the last year. Appetite always good, bowels regular. Patient has always looked upon her stomach as her strong point.

When the writer was asked to see the patient on Nov. 19, 1901, she had felt well since last examined, six months previously. Three days ago she felt dizzy and nauseated while in the street, and several times since then has been so dizzy as nearly to faint. Yesterday she had an attack of vertigo and again to-day, and was barely able to reach home. There was repeated vomiting of greenish bilious matter. The bowels moved thoroughly yesterday owing to fractional doses of calomel prescribed by her husband. No nourishment has been retained for two days, vomiting taking place within a few minutes after the ingestion of food. To-day she is unable to stand or even look at the light, on account of immediate vertigo, nausea, and vomiting. No blood at any time in the vomitus or stool. No history of pain in any part of the body up to this time, except for some soreness in the epigastrium after vomiting. Menses appeared four days ago, and have disappeared to-day. No difficulty in micturition.

The physical examination showed a rather slender but symmetrically built woman, skin very sallow, conjunctiva and mucous membranes suggest a slight icteroid tinge. No real jaundice. Skin warm, neck normal, no glandular enlargement. Pharynx normal, tongue clean but dry. Temperature normal, pulse 85 and of good character. Arteries soft. Lungs normal with full and equal expansion giving no pain. Cardiac sounds all clear at valve areas. Over the pulmonary region a suggestion of a faint systolic murmur (hemic), not transmitted. Cardiac action regular but rather feeble. Abdomen scaphoid; rather tense condition of recti; and very slight tenderness over the epigastrium. Pain does not seem localized to one point. Liver and spleen normal; no appendiceal tenderness or rigidity.

Blood—Hemoglobin, 70 to 75 per cent.; red blood count, 4,880,000; leucocytes, 4000. No poikilocytosis. No other pathologic changes. Urine—1034, acid, amber, turbid (urates), sediment very abundant, pink, semisolid, albumin faintest trace, sugar none. Full of amorphous urates, many clusters of large uratic crystals. Many long, thin, uratic casts; few hyaline casts. No renal epithelium. Much mucus. Few leucocytes. Feces—Liquid, light yellow, no blood noted. No parasitic segments. Vomitus—Small quantity, pale, green color, odor natural. Not tested chemically. Patient was given a capsule of bismuth, cocain and small (gr. 1/24) doses of calomel.

Nov. 20, 1901, next day. Marked change for the better. This morning is able to retain liquid food with relish. Dizzy only when on feet. Skin seems much clearer and whole expression brighter. Tongue clean. No vomiting since noon yesterday. Abdominal walls more relaxed and abdominal tenderness nearly gone. At this time the attack was looked upon as one of vertigo and gastric distress in chlorosis, and rest in bed was ordered with iron and strychnia, and careful overfeeding with milk, according to tolerance.

---

[1] Böttcher, and more recently, Box, Brit. Med. Jour., Feb. 8, 1902, et al.

November 23, three days later, patient is better in most respects, but now complains of a burning pain excited almost at once upon the ingestion of food, and localized over a small area just below the ensiform cartilage. This pain is transferred acutely and constantly to the fifth, sixth and seventh dorsal vertebræ. Bowels opened with an enema yesterday and passages contained no blood. No further vomiting to-day and no headache. On examining the abdomen a slight tendency to rigidity was met with over the epigastrium, but no distention. Just below and slightly under the ensiform cartilage there is a distinctly circumscribed and very tender area, not larger, if as large as a silver dollar. No tenderness at any other point over the abdomen. Appendix negative. Marked pain on pressure over the fifth, sixth and seventh dorsal vertebræ, transferred to and from the epigastric area of tenderness. Gastric ulcer was suspected at this time, though the diagnosis was not believed to be fully warranted.

November 24. Patient this morning seems bright and well, all dizziness being gone. Dressed herself and bathed superficially. Slight quantities of food tasted good, but invariably started the same burning pain over the same circumscribed area. Distinct spot of tenderness present over the fourth dorsal spinous process, and pain is referred to this from the epigastrium. Is sometimes burning, sometimes dull and heavy, and not constant. Tongue quite clean. Epigastric pain on gentle palpation is much aggravated. No tenderness in surrounding parts. Pain last night came one-half hour after eating. This morning is more like a dull weight, after the test breakfast. No nausea or vomiting. Test meal of one roll and glass of water. One hour and a half later 8 c.c. of pale gray fluid were withdrawn. No blood evident macroscopically, fresh or clotted. No lactic acid. HCl markedly increased (0.65 per cent.). Microscopically: full of starch granules, considerable number of red blood corpuscles, few leucocytes, few long thread-like bacilli, no sarcinæ. Urine (a. m): 1013, acid, straw color, clear, sediment abundant, white, flocculent; albumin faint trace; sugar none; chlorids slightly diminished. Many squamous epithelial cells, few leucocytes, no casts, no crystals, considerable mucous; p. m., 1030, acid, amber, clear, sediment scanty, white, flocculent; albumin none, sugar none; urea 2.5 gm. per 100 c.c.; chlorids markedly diminished; few small hyaline casts, much mucus, no renal epithelium, many leucocytes, no crystals.

Nov. 25, 1901. Seen in consultation with Drs. Frederick A. Packard and A. D. Smith. Same symptoms as at time of last note. Pain in epigastrium about the same, sometimes burning, sometimes dull, but nearly constant, localized over the pyloric region, and in the same circumscribed area. Pain still referred to the dorsal spine. Diagnosis of gastric ulcer concurred in by consultants.

A further description of the case may be omitted except to state that the treatment consisted of rectal nutrient enemata of peptonized milk, predigested beef, and egg albumin, all mouth feeding being discontinued. Absolute rest in bed was insisted upon, and a pill of nitrate of silver and opium (gr. 1/12) given q. i. d. On the following day the patient showed positive signs of opium poisoning, and belladonna was substituted in the pill for the former drug. The pain and burning were controlled by carbonated water and at times by a little champagne, though both continued to some degree until the localized tenderness disappeared on the 30th, when for the first time palpation elicited no pain. Beef juice and peptonized milk were then gradually fed by the mouth, the rectal enemata being dropped one by one until at the end of another week the feeding was entirely *per os.* The patient at this time was much emaciated, but there was at once a rapid and steady gain. Gradual overfeeding with milk and eggs and whisky was cautiously attempted and for two weeks the patient ingested from two to three quarts of milk and from six to eight raw eggs daily. She sat in a chair, December 16, for the first time, one month from the time she was placed in bed. The gain in condition continued on iron, strychnia and a careful, overful diet until January 4, when she went out for a short drive. On January 22 she sailed for Europe seemingly perfectly well, and free from subjective and objective symptoms.

The blood picture in May, 1901, when first seen (six months before attack) was hemoglobin, 55 to 60 per cent.; red blood count, 4,650,000; leucocytes, 8200. On Nov. 19, 1901 (third day of attack), hemoglobin, 70 to 75 per cent.; reds, 4,880,000; leucocytes, 4000. Dec. 8, 1901, hemoglobin, 73 per cent.; reds, 4,216,000; leucocytes, 6100. Jan. 18, 1902, hemoglobin, 82 per cent.; reds, 4,360,000; leucocytes, 5200 (sailed for Europe next day). At this time the patient's appearance was better than at any time before or since her illness, and in all probability her blood condition was better than at any previous time in her existence. She was in Europe and Asia, sightseeing moderately, for three months, and returned in what seemed to be first-class condition on April 15, 1902.

On May 6 last her blood was examined, and after several confirmatory repetitions of the hemoglobin estimation, it was recorded as follows: Hemoglobin, 70 to 72 per cent.; reds, 5,056,000; leucocytes, 4000. The pulse was good. There were no subjective or objective symptoms. Patient felt a little tired after the work of rearranging her house for occupation. She was immediately placed on a diet of pure beef juice, squeezed from the beef after a few hours mild heating (not cooking) in addition to her ordinary food. On May 22, sixteen days later, and the day following the cessation of her usual long menstrual period, the blood picture was: hemoglobin, 82 per cent.; reds, 4,500,000; leucocytes, 4800. On June 4 the hemoglobin reading was 87 to 88 per cent., the highest point that had been reached at any time.

The above history has been cited somewhat in detail because it appears to illustrate an occurrence which, to my mind, can not have been an infrequent one in the history of gastric ulcer, and one in which the anemia was known to have preceded by months and probably years what was either a sudden ulcer formation at or near the pylorus, or the sudden exacerbation of a chronic ulcer that had previously given no symptoms. It does not seem possible that the diagnosis could have been a mistaken one, as the symptom complex was recognized at the time as incomplete and rather atypical. There was present, however, on the third day and thereafter, a very typical burning pain in a sharply circumscribed and very tender area, excited almost at once by the ingestion of food, and transferred in a characteristic way to the dorsal spine. The abdomen was scaphoid and the recti rigid, especially over the epigastrium. There was also a marked chlorotic blood picture, a marked gastric hyperacidity, the presence of red corpuscles in the gastric contents and a diminution of the chlorids of the urine, all of which, with the age of the patient, made only one diagnosis probable. The absence of hematemesis is seen in nearly 50 per cent. of all cases, and Boas has recently reported ten cases of gastric ulcer in which there had been no hematemesis, and in the gastric contents of which blood had never been seen with the eye, but was recognized as an "occult" hemorrhage, by means of the chemical tests. The blood, he states, in some of these cases (four out of ten) was repeatedly but not constantly found.

Granting, then, that the case was one of gastric and pyloric peptic ulcer, with atypical, or rather aclassical symptoms (for I do not believe that in this case the two words are synonymous), we are driven to the choice of character of the ulceration between 1, a small symptonless lesion of long standing, suddenly induced in deeper and wider growth; 2, an embolus, or thrombosis, and a consequent ulceration of the infarcted area; 3, a hemorrhagic erosion due to the rupture of some small capillary in the mucous membrane, and 4, an acute peptic ulcer, caused by localized digestion of a gastric mucous membrane, whose powers of resistance to the gastric juice had become so depleted by long standing local and general anemia that it finally gave way to digestive action. In the latter event the severe onset of the symptoms could easily be explained by the nervous shock of the first ulceration, while the later appearance of the typical pain may be readily traced to the gradual invasion of the deeper and more sensitive tissues.

With regard to the first condition, that of a symptomless chronic ulcer, with a violent acute exacerbation, we are not disposed to deny the possibility of its occurence. Welch found that of 11.888 autopsies studied by him from the literature of the Prague hospitals, 164 (1.4 per cent.) showed open gastric ulcers, and 373 (3.1 per cent.) cicatrices or healed ulcers that had not been recognized prior to death. Grünfeld examined 1,150 bodies for gastric ulcer, and found it present in 124 cases (11 per cent.). In 700 cases in which an examination was made, but not with a view particularly to the discovery of gastric ulcer, the latter was found in 4.8 per cent.; and in 450 cases carefully searched for cicatrices ulcer was found in 92 cases (20 per cent.). All of these were found in Copenhagen, where gastric ulcer seems to be a frequent condition. Jaksch (quoted by Brinton) in 2,330 autopsies found 113 ulcers, of which 57 were open sores and 56 cicatrices: Willigk, in 1,600 autopsies, 139 ulcers. of which 74 were open and 65 cicatrices. Finally Barker. in February of the present year. showed in his clinic nine cases of chronic ulcer of the stomach, all of which had had typical symptoms for many months, and in several cases he verified his diagnosis at operation. He speaks of the condition as "a very common form of gastric disease such as you may often see treated in the outpatient department or the medical wards." All of these cases were seen within a short time.

And yet in spite of the frequency of chronic gastric ulcer I hesitate to believe that the symptoms of the case under discussion point to it as a probability here. If symptomless before, why the sudden outbreak with no known cause; and still more cogent. why the prompt healing and seemingly perfect convalescence of what is often and even usually an obstinate condition? These reasons are neither conclusive nor final, but they are forceful and accord with our knowledge of the usual behavior of gastric ulcer and must be considered. I do not, therefore, exclude the possibility of a chronic ulcer, though I do not consider it the most likely condition.

Upon the second possibility, that of an acute ulcer of embolic or thrombotic origin, I must look with still less favor, since there was no condition known to be present that would suggest an embolus; while the only known possibility of a thrombus rested in the anemic condition which was of long standing but of a temporarily less degree than usual owing to treatment. We must. moreover, again consider the rarity of thrombosis and embolism at this point, and the important fact that of the few times that the latter condition occurs by far the most numerous are at the cardia. Walsh states that no one has ever experimentally produced a solitary embolus of the pylorus. Hemorrhagic infarct has, however, been observed postmortem in the stomach, both alone and with ulcer formation; and in such cases thrombosis may have been present, either as a causal or consequent condition. Rindfleisch reports such a case, and v. Recklinghausen another. Both state, however, that the condition is a great pathologic rarity; and this very rarity prevents our considering thrombosis as a probable condition, in the presence of a more satisfactory explanation.

The third suggestion is that of a hemorrhagic erosion. All authors mention this as a possible early stage of gastric ulcer, and all pathologists refer to it as a frequent postmortem finding. No one can deny that a small hemorrhage may have occurred as a result of the vomiting during the first days of the attack. And yet there was a gastric condition present at the earliest stage that needs more of an explanation than that of an erosion, and which possibly, and to my mind probably, was due to a superficial ulcer already present; this in view of the later symptoms. If a hemorrhage occurred, its immediately surrounding area might easily have offered a susceptible focus for gastric digestion; but this would not have explained the early violent attack (which in some features suggested gastric perforation) as well as an ulcer newly formed, still superficial and due to causes that will be discussed immediately.

We are led finally to the theory which I consider the most rational. and which I believe may be the explanation of many if not the majority of acute and chronic peptic ulcers. It has already been intimated that the most likely condition appears to have been an acute peptic ulcer, located as usual. at or near the pylorus, and due to digestion of a gastric wall rendered susceptible to such action by a long-standing anemia, a consequent poverty of blood and inanition of the part, in the presence of a hyperacid gastric juice. My reasons for arriving at these conclusions are as follows: We were fortunate to have examined the blood of the patient six months previous, and knew that it was markedly deficient in hemoglobin and to a lesser extent in red corpuscles. The appearance of the patient had from childhood suggested a chlorotic condition. During this entire time and until the attack occurred gastric digestion had been apparently faultless, and certainly was symptomless. We therefore find ourselves in the possession of two important facts; first. that the patient for months and perhaps years had been lacking in hemoglobin and red corpuscles; and secondly, that up to the time of her final onset of symptoms nothing had occurred to even attract attention to the stomach. This, we may add, is never the case in a recognized chronic gastric ulcer, which has its own succession of dyspeptic, and finally ulcerative symptoms, that are always present, though not always ascribed to the correct cause.

It has been repeatedly shown (Ritter u. Hirsch et al.) that with the chlorotic condition is often associated a hyperacidity of the gastric juice. and as if to form a combination of conditions most liable to cause self-digestion of the gastric wall, Pavy, Silbermann and others have shown that in all anemic conditions the alkalinity of the blood is more or less decreased. We have, then. in long-standing chlorosis or anemia an abnormal power in the digestive action of the gastric juice, while the main influence of resistance against this acid content, viz., the alkalinity of the blood that fills the capillaries. is removed.

There were present in our case the ideal conditions for the formation of a peptic ulcer at some point in the stomach, the entire wall of which was suffering primarily from a lack of blood in sufficient quantity and quality, and secondarily from the lack of protection ordinarily afforded by the alkalinity of a normal blood supply.

The reasons for the frequent involvement of the pylorus in digestive lesions have been repeated so often that they need not be cited here. I wish, however, to call attention to a fact with reference to the circulation of the pylorus to which I find no reference in the literature, and which to my mind lends a still greater emphasis to the theory that gastric ulcer is often if not usually dependent on pyloric anemia, or the results of circulatory disturbance. While the blood supply of the stomach is a free one, especially to the cardial end (gastric, left epiploic and the brevia), and a sufficient one to the pylorus (pyloric and the right epiploic), the venous outlet is free only from the cardial end of the stomach. The latter is drained by the large coronary vein which passes along its lesser curvature, by the left gastro-epiploic and the vasa brevia. The pyloric end of the stomach, however, has a much smaller outlet in the pyloric and the right gastro-epiploic veins, both of which are small, while the former enters the portal vein almost at a right angle, and the latter joins the superior mesenteric under the same angular disadvantage. In normal conditions, and with normal blood pressure, this venous exit is ample and able to discharge the pyloric blood at a rate prompt enough to avoid stagnation or congestion. In anemic conditions, however, in which the blood pressure is often so low that it seems impossible for the heart to force a drop from the deeply pricked finger, an outlet that is ordinarily sufficient may easily become inadequate and the cardiac activity too slight to force the pyloric blood into and against the rectangular stream of the portal system. In short, a venous congestion of the pylorus will in all likelihood be added to an impoverished arterial blood supply, a lowered alkalinity of the blood and a hyperacid condition of the gastric juice.

It must be frankly admitted that peptic ulcer sometimes occurs in cases in which there is no hyperacidity; but under such conditions as have been pictured hyperacidity seems hardly necessary to self-digestion, and a normal or even subacid condition might easily erode the depressed gastric wall. This actually occurs postmortem, as soon as the protective circulation of the gastric wall ceases to flow, and is often seen in the cadaver.

As to the frequency of association of chlorotic and other forms of anemia there is no lack of evidence. V. Limbeck states that either the chlorotic state may precede or that the stomach impairment may cause the blood condition. Welch suggests that amenorrhea, chlorosis and anemia favor the development of gastric ulcer. He seems to intimate, however, that the anemia follows (p. 487, Pepper's System) rather than precedes the ulceration. Osler goes a step farther in stating that "anemia and chlorosis predispose strongly to gastric ulcer," and both Ewald and Leube speak of a possible causal connection between anemia, hyperchlorhydria and the condition in question. Strümpell, however, believes that the influence of chlorosis may have been exaggerated. Gempt (to whom reference has already been made) seems to have been one of a very few writers to express the conviction that the anemia and the inanition consequent on it, particularly of the pyloric end of the stomach, was the primary predisposing condition.

Many interesting experiments have been attempted in the study of the pathogenesis of gastric ulcer, such as the ligation of the arteries supplying the stomach (Pavy), the introduction of multiple emboli into the gastric arteries (Panum and Cohnheim), the ligation of the portal vein (Müller), trauma through the abdominal wall (Ritter), and more recently, the cutting of the vagi (Saitta, Yzeren). In the last year experiments have been reported by Fütterer of Chicago that led him to conclusions much in line with my own theory of peptic ulcer formation. Fütterer found that in animals in whose stomachs ulcers had been artificially produced, there was a marked tendency to healing as long as the hemoglobin was present in full proportion. As soon as he destroyed the hemoglobin he found that this tendency to heal disappeared and was followed by the characteristic appearance of peptic ulcer as seen in man. From this he concludes that peptic ulcer depends mainly on the lack of hemoglobin, and states that he feels warranted in asserting "the dictum that an ulcer of the stomach can form only when there is a certain amount of hemoglobin lacking, and that it must heal when the hemoglobin percentage is increased to a certain amount." His conclusions hardly seem fully warranted, however, in the light of clinical results. There are on record innumerable instances of gastric ulcer, treated with success, and yet in the handling of which the anemia was totally neglected, because it was not considered the causal condition. Cornils cites the occurrence of a gastric ulcer in his own person, that was cured without any other treatment than rest and a purgative medication. He also notes other similar cases from his experience. Pariser in the present year in his study of gastric ulcer dwells at length on the local treatment by remedial agencies, and barely mentions the treatment of the anemic condition. In fact, few only of the text-books emphasize this need, and their authors have all of them cured gastric ulcer perhaps many times by simple and primarily local methods. We must not forget, however, that all modern forms of treatment include absolute rest in bed and that such a provision means less of a drain on and therefore a gradual bettering of the blood supply, though probably not an increase of the percentage of hemoglobin. It seems necessary to believe that in men both local and systemic treatment are required; but it is equally certain that peptic ulcers occur in individuals with a high hemoglobin reading (cases cited by Cabot, Greenough and Joslin, etc.), and that often they heal without any change in the hemoglobin percentage. The latter fact is evidenced by the large number of cicatrices (i. e., healed ulcers) found postmortem in cases that have had no treatment whatsoever, and have died as the result of another condition.

We must agree with Fütterer, notwithstanding, that the hemoglobin percentage is an important matter, both in the causation and in the treatment of the condition, and only differ from his belief that it is the only or the main factor in the case. Cabot in 1897 reported 28 cases of gastric ulcer, of which 13 showed less than 50 per cent. hemoglobin, and only 4 over 80 per cent.; while of the 21 cases in which the red corpuscles were counted 5 had under 3,000,000, and the average red cell count was 3,800,000. As a rule the color index was low, though Cabot quotes Osterspey to show that it may be high. He also quotes Grawitz in citing a case of peptic ulcer in a very pale girl whose hemoglobin registered 90 per cent. and later 91 per cent., and in whom the red corpuscles numbered 4,140,000, and later, 4,340,000. In this case, however, the dry residue of the serum was only three-quarters of the normal amount, and the girl was really anemic, the contradictory blood picture being due to anemic concentration. Oppenheimer has also called attention to the great pallor in certain cases with normal counts and hemoglobin readings. He cites six cases of gastric ulcer, however, of which the highest reading was hemoglobin 75 per cent., with 4,100,000 red corpuscles, and the lowest, hemoglobin 25 per cent., with 1,200,000 red corpuscles, while the other cases ranged between these figures. Greenough and Joslin have studied the cases of gastric ulcer treated in the Massachusetts General Hospital for the years 1888-98, and out of 13,097 patients treated found 187 cases of gastric ulcer (1.4 per cent.). There was pallor in 131 out of the 164 patients regarding whom any note of this condition was made. Hemoglobin and blood estimations were made in 73 cases, in 34 of which the hemoglobin was below 50 per cent., and in 64 below 80 per cent. The red blood cells were counted in 43 cases and in 24 the count was below 4,000,000. The writers seem to look on the anemia rather as a symptom than as a cause. DaCosta reports 20 cases of gastric ulcer in all of which the hemoglobin was below 80 per cent., in 8 below 50 per cent.; the series averaging 57.8 per cent. The red blood cell count averaged 4,017,000. Nearly all authorities note an absence of leucocytosis, though this is not an invariable rule.

A number of interesting cases somewhat similar to the one reported in this paper have appeared in recent medical literature, among which Maunsell reports one of a servant girl who had suffered from anemia for some months, and for some weeks from uneasiness in the stomach. Perforation occurred with a sudden onset of pain. Death followed the operation and at the autopsy "a single ulcer of the acute type" was found.

Shettle reports a case of "an anemic girl aged 17 years" who "had suffered from anemia with dyspeptic symptoms for some time, but had none of the typical symptoms of gastric ulcer." Suddenly she had pain, fainted, vomited, and then ensued general abdominal pain. Operation was performed, and an ulcer was found near the cardia.

Goodhue cites two cases, one of a woman 24 years old and six months pregnant, "anemic and chlorotic since puberty, with amenorrhea, dysmenorrhea, and metrorrhagia, at different times." Miscarried on Sept. 14, 1893. At this time gastralgia, but no other symptoms than those of dyspepsia. On November 21 of the same year she experienced nausea and coffee-ground vomit; there was blood in the vomit and feces, and burning and boring epigastric pain. The case finally recovered.

His second case was noted in an anemic and neurotic woman of 32 years, a nurse who had had amenorrhea since puberty. For four or five years she had had digestive troubles. Suddenly perforation took place with pain and vomiting of blood, though the case was not properly diagnosed until a late consultation, and death followed. The autopsy showed an ulcer in the pyloric region.

Finally Stratton, in March, 1902, reports a case in which the pain was more severe when the stomach was empty, with spells of pain coming and going every four or five hours. The attacks lasted a week or ten days, and were induced by exposure to wet and cold rather than by food. A tender spot always localized over the epigastrium in the same area was present, but the patient never vomited blood, food, or gastric secretions. The tenderness entirely disappeared between attacks. Finally, under an unusual exertion, there was sudden intense pain; then none for 10 minutes; and again a violent pain in the epigastrium. Operation was performed and perforation found in the anterior wall near the pylorus. This case is cited especially because of its many features resembling those of the one now reported by myself. Before summing up our conclusions it will be well to note that Saitta, in 1900, in treating two cases of gastric ulcer (one following long-standing gastrosuccorrhea, and the other succeeding digestive disturbances, with nervous involvement in both cases, as well as chloro-anemia, and neuralgia), thought of the vagus as the cause of the trouble, and as furnishing a predisposed soil. He severed the nerve on both sides in 16 rabbits, and fed them on a weak solution of hydrochloric acid. By this means he induced multiple ulceration, with general gastritis; in control animals, with the pneumogastrics intact, the procedure had no effect.

Yzeren, in 1901, reported a series of experiments, also in rabbits, to justify Talma's theory that gastric spasm is the underlying cause of chronic peptic ulcer. By cutting the vagi below the diaphragm he found that he could produce ulcers corresponding absolutely with those occurring in the human stomach. They appeared several days after the operation, and showed no tendency to spontaneous healing. Usually only one ulcer appeared, and this in the pyloric region close to the lesser curvature. It was preceded by necrosis of the mucosa, while the structures more remote from the pylorus were not affected. Gastro-enterostomy or incision of the pylorus seemed to prevent or delay the ulcerative process. After the operation the stomach was distinctly harder, indicating spasm, this spasm of the gastric muscle helping to produce anemia of the mucosa, and resulting in necrosis. As the muscle is thickest around the pylorus, the lesion is most likely to be situated here. Both of the latter observers, it will be noted, produced, and studied the effects of, *a local pyloric anemia.*

Ewald, in his paper before the German Congress on Internal Medicine, held during the present year, considers Yzeren's theory very improbable, and believes that both conditions (ulcer and spasm) are the result of hyperacidity. His own figures, however, would rather convince the unbiased observer that in at least 76 per cent. of the cases some other cause than hyperacidity was at work, since in just this percentage of cases he found hyperacidity absent. He states that he has seen over 1080 cases of gastric ulcer in the last 10 years of which 34.1 per cent. showed hyperacidity, 66.8 per cent. normal acidity, and 9 per cent. subacidity. Blood was frequently found in the contents, and hematemesis was present in 203 out of 364 patients (54.5 per cent.).

Our conclusions with regard to the causation of peptic ulcer of the stomach are as follows:

1. In many, and perhaps in most cases, a high grade of anemia precedes the appearance of peptic ulcer, and this anemia usually assumes the chlorotic form.

2. With few exceptions, gastric ulcer is attended by the symptoms of marked anemia. In certain cases in which the blood picture fails to show a reduction in the hemoglobin percentage and in the number of red cells the fact seems to be due to concentration of the blood dependent on anemic causes.

3. General anemia implies anemia also of the pylorus, and consequent inanition of its mucous membrane.

4. The venous outlet from the pylorus is one that in anemic conditions would predispose still further to an unhealthy condition of the muscular and membranous coats of the pyloric wall.

5. Hyperacidity is usually present in chlorosis and often in other forms of anemia; and when present in any condition it is an influence predisposing to gastric ulcer, when associated with an anemic gastric wall.

6. Hyperacidity is not essential to self-digestion of the stomach wall, provided that wall lacks the proper nourishment and stimulation of a healthy or sufficient blood supply.

7. Any form of hemorrhage, menstrual, operative, or anemic, may either predispose to, or accentuate an already present anemic condition of the gastric wall, and

such hemorrhages are *de facto*, often followed by gastric ulcer.

8. Finally, the foregoing facts, in association with the general one that gastric ulcers are seen almost invariably in anemic subjects, warrant the conclusion that blood poverty is a leading, and the usual, predisposing cause of peptic ulcer.

DISCUSSION.

Dr. Fenton B. Turck, Chicago—This subject is one of great interest and importance. The first part of the paper has dealt with well-recognized etiologic factors. He did not call attention to the recent observations made with special reference to the muscular activity of the stomach in which it was determined that the lack of motility was one of the chief factors in cases of gastric ulcer. Recently Kocher called attention to the ulcers found in the jejunum following a gastro-enterostomy; here a true peptic ulcer was found. The conclusions reached were that such cases, in which there was a lack of motility and a lack of the muscular contraction together with disturbances of the splanchnic circulation, especially the portal circulation and circulation in the intestines, resulted in true peptic ulcers of the jejunum. In my own observations carried out one year ago I made a large number of experiments with guinea-pigs and rabbits, keeping them in small cages in which they scarcely had room to turn around, confining them in the dark; at the end of a certain time only seven or eight were alive, some showing the chlorotic type of blood, and in two were found ulcers which had the appearance of peptic ulcers which failed to heal and showed other evidences of true gastric ulcers. The evidence adduced seemed to show that, clinically, there were two important factors in their causation: 1, disturbance of the circulation; 2, a lack of gastric tone, or motility, or gastric myasthenia. Bramwell has shown that most cases have occurred in girls coming from the country leading sedentary and indoor lives. It has been noted that girls with poor circulatory disturbances since early childhood at puberty acquire these ulcers and it is stated that the early environment and personal hygiene were the direct factors at play, causing a disturbance of the circulation in the splanchnic area; this interference with the muscular tone of the stomach accounts for a large number of the lesions.

Dr. James J. Walsh, New York—With regard to the causation of gastric ulcers it is pretty well recognized that the basis for the development of the lesion is an anemic condition, and I think that nearly every general practitioner has realized that all such cases have a traumatic element which may occur in many ways as, for instance, in cooks, from swallowing hot food; in seamstresses, from the vibration of the sewing machine against which they lean; in those who use the knitting machine, from the same kind of vibrations; in typewriters, from vibration of the machine against which they lean; and in clerks, from leaning against the desks. I have seen two cases occurring in men. One was a carpenter who leaned heavily against his chisel while smoothing boards. The other was a shoemaker who cut leather while holding it firmly pressed against his stomach. Among the poorer classes, the wearing of old corsets poorly made may have a causative effect, because of inequality of compression that interferes with the circulation of the abdominal wall and reflexly the stomach wall and because of the traumatic effect through a thin abdominal wall on the stomach itself. The prophylaxis of gastric ulcer would seem to demand the warning of anemic patients against all such possibilities.

Dr. H. B. Favill, Chicago—I think we all agree with the general importance of this subject and its general interest and, also, with the general clinical conditions preceding the trouble. But the most interesting point in regard to it is the active determining factor to be found in the deep ulceration, the underlying factor being acknowledged. I am of the opinion that the recent view advocated, and becoming well established, that there is a lack of hemoglobin, and that this lack of hemoglobin is an essential factor, without which such ulcerations will not take place, is to be kept in mind. It is reasonably well established in a considerable wandering literature that, experimentally, defective hemoglobin can be shown to be an adequate determining cause. Without going further into the point for the sake of argument I only want to say that this bears on the subject of therapeutics enormously. If it is true that defective hemoglobin is the essential element in such ulcers, it certainly is true that the restoration of the hemoglobin is the most essential element in restoring the integrity of the mucous surface. Rectal feeding and rest in bed, then, is not the rational method of dealing with ulcers of the stomach if their genesis is as it is supposed to be. This is all the suggestion I care to make, although the whole subject, viewed from this point, seems pregnant with importance, bearing on the management of the condition.

Dr. Willson, in closing—I am sorry that in the short time at my disposal I could not make reference to the enormous amount of experimental work that has been done in this line. All of these experiments have led to the conclusion that there is either a local or general anemia present in every case of gastric ulceration, and that when this condition of anemia is corrected there is a marked tendency to heal. There seems also to be no question, clinically, that the great number of cases of gastric ulcer occur in patients who have suffered from an evident anemia, and that this anemia usually assumes the chlorotic type. Many of these ulcers follow hemorrhage of one form or another. Welch has referred to the frequency of cases that occur at or about the menstrual period, to which the name of "menstrual ulcer" has been given. On the other hand, gastric ulcer may occur in persons with a perfectly normal blood count, who seem to be in a state of good bodily nutrition. Moreover, for many years gastric ulcer has been treated without reference to the blood condition, and many cases have been completely cured (to say nothing of those that have cicatrized and escaped recognition until the postmortem examination). I have already shown that these facts call into question the correctness of such sweeping conclusions as those arrived at by Fütterer and others. I do not, therefore, wish to take the ground that gastric ulcers occur only in patients who have an evident blood poverty; or that they heal only when the blood supply has again been perfected. But that when blood poverty is present, whether local or general and whether of quality or quantity, ulceration is likely to occur; and that both the occurrence of the condition, and the likelihood of its healing, bear an intimate though not an invariable relation to the quality and quantity of the pyloric blood supply.

THE LESIONS IN THE NERVOUS SYSTEM IN RABIES.

Specific lesions are often of importance in the diagnosis of disease. In a case of rabies a method of rapid diagnosis, by means of histologic examination of the nervous system for instance, has long been sought because of the importance of recognizing the existence of rabies in animals as well as in man. In the case of dogs, for instance, suspected to be mad, it may be of vital significance if a definite diagnosis of rabies could be established within two or three days. Babes held that the so-called rabic tubercle was pathognomonic of rabies. The rabic tubercle consists of an accumulation of cells, especially in the medulla and upper part of the spinal cord, around the central canal and about the motor cells. Various degenerations occur at the same time in the cells of the bulbar nuclei. Perivascular infiltration, commonly seen in many acute diseases, also occurs in rabies in which the smaller blood vessels of the cord and bulb also contain an unusual number of leucocytes and cells. But later observations have demonstrated that the rabic tubercle of Babes may also occur in other conditions, and the changes described by him in the medulla and spinal cord in rabies lost some of the diagnostic importance that he was inclined to give them. Van Gehuchten and Nelis laid special stress on the lesions observed in the ganglia. These lesions consist in the accumulation of epithelioid and round cells, largely derived from the capsular epithelium of the nerve cells; in part, also, from the blood vessels. These cells accumulate around and finally replace the neurocytes. At first these changes were regarded as specific, but later Van Gehuchten acknowledged that the destruction of nerve cells from any cause may result in similar cellular reactions. As the matter now stands the following seems to be a reasonable view to hold in regard to the nervous lesions of hydrophobia and their diagnostic significance. When present, the changes in the ganglia, taken in connection with definite clinical manifestations, constitute a trustworthy diagnostic sign of rabies. Absence of these changes does not necessarily signify that rabies is absent; the lesions in reality constitute only contributory evidence. The rabic tubercle of Babes is also sufficiently significant to acquire diagnostic importance; of most value, of course, in those cases in which it may be impossible to obtain any of the ganglia, which in all cases offer simpler and easier material for examination.

It has long been customary whenever a mad dog has appeared to immediately destroy the animal. In the interest of accurate diagnosis this custom should be replaced by confinement under suitable conditions and careful observation of the animal until such time as may be required for the clinical manifestations of the disease to become definite and typical. After the death of the animal, no matter whether early or late, spontaneous or otherwise, the materials necessary for the study of the lesions in the nervous system should be properly preserved (10 per cent. formalin solution in water will answer) and subjected to a careful examination for the lesions referred to in the foregoing. In this way it is hoped that the diagnosis of rabies may be established definitely more frequently than is now the case, and that greater accuracy of statistics and prompter application of specific treatment may be secured. It will be pardoned, no doubt, if attention is directed again to the fact that here is another instance of the value of laboratory methods in practical medicine.

QUACK ADVERTISEMENTS IN RELIGIOUS PAPERS.

There lies before us a weekly paper published in Cincinnati, under the name of "The Lookout." It is in appearance a medium for advertising proprietary medicine and the worst sort of medical fakers, with sufficient religious matter sandwiched in to allow it to masquerade as a religious paper and under this pretext to gain entrance to the Sunday-schools and homes of unsuspecting people. Although we have been informed that it is the weekly Sunday-school paper of a certain religious sect, this does not appear on the copy which is before us. The number at hand consists of 16 pages, of which a total of 4 pages is occupied by 30 advertisements of the variety indicated. On the fourth page, the second chapter of a serial story is punctuated by two of these advertisements, one of a compound which cures "spring humors," and the other of a wonderful "golden medical discovery," which cures diseases of the stomach, purifies the blood, etc. On the following page, a Sunday-school story is interrupted after about half a column to make room for a most magnanimous doctor to tell the people that he does not want any money. He has spent a lifetime in learning how to "strengthen the inside nerves" and his "method always succeeds, save where some condition like cancer makes it impossible." He insists that you owe it to yourself to read his books, six of which he offers free, one of them "for men (sealed)." On the same page, an institute in Philadelphia announces that "stammerers are being cured" and a D.D. of Indianapolis assures the reader that "those whom he can not cure, can not be cured." Almost one-half of page 6 is devoted to the exploitation of "catarrh remedies," one being embellished by the picture of a very spiritual-looking, surpliced choir-boy who, presumably, is singing the praises of the wonderful cure. Opposite the page given up to the "prayer-meeting," a complete page is assigned to what must be a very remunerative advertisement. There is a full-sized picture of the bottle with the picture on the label of a safe, across the top of which appears the magical Indian name. To "test your kidneys" you are directed to put some morning urine in a glass or bottle and let it stand for 24 hours when, if it is milky or cloudy, or contains a reddish, brick-dust sediment or if particles or germs float about in it, your kidneys are diseased. The test has been most adroitly worked out to suit all kinds of temperatures, and so as to allow few persons to labor under the idea that their kidneys are healthy.

Charcoal tablets and pink pills are thoroughly ventilated to the extent of over one-third of page 11. On page 12, in an advertisement of one column. Dr. X., whose funereal picture is exhibited, announces that he has surely discovered the "elixir of life." "With the aid of a mysterious compound, known only to himself, he is able to cure any and every disease that is known to the human body," and what is equally wonderful, "the remedy is free to all." On the same page, another A.M., M.D., Ph.D., whose abundant. flowing beard is sufficient evidence of his wonderful wisdom, promises to dispel cases called incurable by means of "a marvelous treatment discovered by an association of scientists." Perhaps there may be a science which deals with quackery? We will not dwell on the cures promised for cancers and tumors, deafness. fits, opium and liquor habits, piles, nor the "woman's discovery." a "simple, harmless,vegetable remedy that will quickly cure all female diseases as well as the piles without the repugnant methods in general use by physicians."

On the editorial page there is an item with the heading: "By Way of Excuse." In it we find—"A Christian can often overlook the faults of his brothers in the church. but the sinner can not. A flaw or a splash of mud will be enough to fill his soul with disgust toward the professed Christian." To any physician who reads this paper, the filth and falsehood in its advertisements are sufficient to effectually neutralize all the professions the supposedly Christian publishers could put into a large library of books. The writer of the item above referred to says that "the thief who steals a man's purse may plead that he is prompted by crying physical needs, but the man who takes nothing, but allows people to believe that he is a thief. has no such extenuating plea to make." Under which class do the management of this paper and its allied fake advertisers belong? From lack of information many of the laity may overlook the shameful and even criminal results which follow the dissemination of such a paper, but for a religious paper to act as the means by which the unfortunate sick are placed at the mercy of such quack mercenaries is beyond any excuse. The people into whose houses this paper comes may well be on the lookout. It is the duty of physicians to exert their influence to keep it out of the churches and Sunday-schools with which they and their families are connected. It is an open insult to the respectable medical men in a community for such a publication to be circulated by church people under the disguise of a religious paper.

MILD PARANOIA AND PUBLIC SAFETY.

Despite the general interest instinctively taken by the public in medical subjects, the important principles of medicine seem to become common knowledge only slowly, more slowly. indeed, in many respects than the "greatest good of the greatest number" would demand. In this direction the medical profession undoubtedly fails somewhat to do its whole duty.

One direction in which this lack of public enlightenment on truths recently developed by scientific medicine is of especial import is that as to the general nature of mental derangement. Ask the average man to briefly describe a dangerous case of insanity, and probably he would depict acute mania in its violent stage. This still to the lay mind is the typical form of madness, and the one he fears most to meet. On the other hand, the average man has a good notion of what a "crank" is, and cranks are to him a source of mirth and of innocent merriment; he has not yet learned to fear them. It is the relation of crankiness to what he already recognizes as madness that is most lacking in the public's psychiatry. In short, the people need to be taught (and who but the physician can teach?) that, other things being equal, the crank developing into the paranoiac is worse deranged and far more dangerous than even the maniac who raves. In the maniac one discovers only, in type, a quantitative disturbance in normal psychophysical function, while in the paranoiac the disorder, while almost wholly mental, is at the same time qualitative. It is on this latter account that monomania involves possibilities of motor ideation and of consequent conduct which may entangle, and that most dangerously, all with whom the patient has to do.

This important difference the specialist, of course, knows well, and from him the public occasionally gets a note of warning. It would yield a common benefit if the general practitioner also fully realized that paranoia is the typical insanity; that cranks are either mild or incipient paranoiacs; that exacerbations of the disease frequently occur without warning in what is apparently the most harmless case. making the subject perhaps the most dangerous of the mad. The delusions and the hallucinations often are most perfect and surprisingly elaborate, so that the deranged agent brings to bear through his often powerful will all of the skill and cunning both of body and mind of which man is capable, and untrammeled quite by all of those restraints, moral and emotional, which lead the sane man to balance every act before it is performed. In the paranoiac, then, the public encounters an agent absolutely irresponsible when his particular monomania is set in action by the needful external and internal conditions.

How may common knowledge of paranoia as a malady of this irresponsible nature be best spread among the people. that the dangerous ones may be the better restrained? Many families endure very much in silence before sending a loved one even to the best of hospitals for the insane, partly from pride, partly because a popular prejudice still remains from the days of cell and straw and chain. This immediate problem of enlightenment is but a part of the larger one of instruction in general prophylaxis which mankind at present needs so much. It will come soon or late.

Meanwhile there is required on the part of health officers and alienists and general practitioners a more stringent watch and registration of incipient and mild paranoiacs. It seemingly should be the duty of boards of health to keep a list of the subacute paranoiacs and even of the well-known cranks within its jurisdiction, and to keep over these a watch lest they do harm and that they may be confined in a hospital when there is need. We are only beginning to learn the proper usefulness of boards of health. Ever better and better the victims of the contagious fevers and other infectious diseases are isolated from their fellows for their common good. Paranoia should be added to this list for reasons similar in effect. The time seems ripe and, indeed, over-ripe, when patients suffering from even a mild attack of the always dangerous monomania should be watched lest they harm needlessly themselves, their friends or others. That they are not yet so constrained is one of the lacks of our day which men a few years hence will find difficult to understand.

PREVENTABLE BLINDNESS.

About twenty years have passed since Credé showed that gonorrheal conjunctivitis of the new-born, the scourge of maternity hospitals and the cause of so much blindness, can be positively prevented. Every text-book on the eye has since that time described Credé's method and preached its necessity. Every text-book of obstetrics has contrasted the state of affairs before and since the introduction of "Credé" in lying-in institutions, and yet how little is this simple and efficient prophylactic used outside of hospitals.

Some years ago Cohn learned by means of statistic correspondence with all physicians in Breslau, that in that city 2 per cent. of all children born in private practice were still allowed to contract the disease and risk blindness. The same oculist, so well-known for his statistic researches, has recently shown that in institutions for the blind in Germany 20 per cent. of the inmates still owe their blindness to the neglect of the obstetrician. This percentage, contrasted with 28 per cent. of 25 years ago, shows but a very small progress in preventive medicine in actual practice.

Yet Credé's method has been almost universally employed in hospitals and no voice has ever been raised against its efficiency. Many series of thousands of cases have been published by different authors and all agree that even with 10 per cent. or more of demonstrable gonorrhea in the mothers the offspring are absolutely protected by the faithful employment of nitrate of silver instillations. It has been urged, however, that Credé's method may cause an unpleasant, even an inflammatory, though not dangerous, reaction of the conjunctiva. It was especially Cramer who recently again described undue conjunctival irritation following the use of nitrate of silver in babes.

In an able article, written in a tone of conviction, these objections to Credé are refuted by Leopold.[1] He shows by quotations from Cramer that the latter did not use Credé's method with the simplicity and gentleness recomended by Credé himself. Credé's original directions were to open the eyes immediately after the bath, and to allow a single drop of a 2-per-cent. solution of nitrate of silver to descend from a glass rod on the cornea by contact. No other manipulation of any kind was to follow. By carrying out these directions literally no unpleasant reaction was seen by Leopold and his assistants in some 30,000 instances. The efficiency of the method is illustrated by the records of the year 1898. Among 2146 birth there were three instances of conjunctivitis and all three could be traced to inefficient applications of Credé's method by some untrained pupils during a rush of obstetric work. A later secondary infection can, of course, not be prevented by the use of Credé's installation at birth, which counteracts merely the infection at the time. In a final note, Leopold adds that he has used a 1-per-cent. solution of nitrate of silver on the last series of 698 children without provoking even the slightest irritation and with absolute prevention of primary infection of the eyes.

Most physicians realize to-day that in every instance in which the obstetrician can not be sure of the absence of gonorrheal infection (and how often can he be?) the slight trouble of using Credé's method is repaid by the certainty of avoiding blindness. But unfortunately, there are some who will not profit by the experience of others and who will have to see personally the havoc done by conjunctivitis neonatorum before they will take the pains to guard against it.

THE PSYCHOSES COMPLICATING TYPHOID FEVER.

Symptoms referable to the nervous system are peculiarly distinctive of typhoid fever. They may appear at any stage of the disease, from the very onset far into convalescence, and they are to be attributed in part to the intoxication resulting from the underlying infection, in part to the pyrexia and in part to the secondary asthenia and the attendant changes in the fluids and tissues of the body, together with the individual predisposition. Of these symptoms headache is the most common, while sleeplessness, delirium, stupor and muscular twitchings are fairly constant. More persistent mental derangement is much less frequent, having been observed by Curschmann in but 42 patients among 4,000 cases of typhoid fever. In 35 of these the mental disturbance occurred during the febrile stage, in 2 during defervescence and in 5 during convalescence. In 32 the mental state was one of melancholia or quiet delirium, with or without hallucinations, while in the remainder conditions of excitement or even maniacal states were observed.

---

[1] Berliner klinische Wochenschrift, No. 33, 1902.

In a recent communication Dr. Clarence B. Farrar[1] records four cases representing types of psychoses occurring in connection with typhoid fever, and discusses current views with regard to the effects of the typhoid process on the mental functions. As a result of this study of the subject he points out that typhoid fever attacking a sane individual may leave him free from psychic symptoms or give rise to all gradations of mental disease. The severity of the symptoms does not necessarily stand in relation to the height of the fever or the intensity of the infection. Persons of psychopathic heredity are more prone to alienation, especially initial delirium. than those not thus burdened. A protracted exhausting fever predisposes to an asthenic psychosis. A second or a third attack of typhoid fever is more likely to be complicated by mental troubles than the first. Initial delirium is the rarest form of mental disease observed in connection with typhoid fever, and it exhibits the most rapid course and has the worst prognosis, over 50 per cent. of such cases terminating fatally. It is essentially the expression of a severe intoxication and it is often responsible for error in diagnosis, so that in any case the association of mental derangement with fever justifies the suspicion of typhoid fever. The psychoses of the febrile period are the most frequent and afford the best outlook, although 25 per cent. persist for varying lengths of time into or after convalescence. They are especially attributable to the elevation of temperature and its consequences. The asthenic psychoses—excepting isolated delirious conceptions and cases of typical collapse delirium—present a long and tedious course and a doubtful outlook, with evidences of serious cerebral changes. They develop on a basis of exhaustion, anemia and malnutrition.

From the evidence it must be concluded that a post-typhoid predisposition. in the form of irritable weakness, exists, on which may develop late psychoses, with a dubious prognosis. As a result of the metabolic derangement accompanying severe infections an attack of typhoid fever has been followed in many instances of so-called recoverable psychoses by temporary improvement or recovery. Neither in its clinical nor in its anatomic picture is the psychosis of typhoid fever distinctive. The elements of intoxication, infection, temperature, exhaustion, anemia, of whatever origin, may cause similar or indistinguishable processes. The determining factor of susceptibility to mental disorder as well as of the course and event may be expressed, in a word, as the mental reaction coefficient of the individual together with the physical basis.

THE REPORT OF FAILURES.

A British dentist had to defend a suit for malpractice which was based on, or rather incited by, his publication of a case presenting features of interest to his profession. The patient's attention was called to the publication and she interpreted it as a confession of bad management of her case, hence the suit. At the trial it was conclusively proved that the accident was not due to any want of care or skill, and the prosecution failed, but the instance is a suggestive one. Physicians are often blamed for not publishing their failures and their accidents, and it is generally assumed that their reason for this is the dislike to say anything that might reflect on their skill. If such publication is even remotely liable to involve them in malpractice suits they have a still better reason. It will be unfortunate, however, if such a cause should prevent the publication of valuable case reports in medical journals, and it would seem that in some way or other such publication could generally be made unavailable for any hostile purpose. The public does not, as a rule, read medical journals, but there are some more or less remote chances that a patient may come across and recognize an account of his own case. Hence it would be advisable in reporting unfavorable cases to avoid making them too intelligible to the lay public or giving unnecessary data that might lead to their identification. The risk of trouble is small, but it is well to minimize it still more if it can be done. It is to be hoped that this case will not have the effect to deter physicians and surgeons from giving out what may be of value in their experience, and that it will not in any case ever lead to the suppression of important facts.

AGGLUTINATION OF TUBERCLE BACILLI AND NEW TUBERCULIN.

During the past few years there has been a great deal of investigation devoted to various phases of agglutination, and of late the agglutination of tubercle bacilli especially has received much attention. It seems that the principal result of the work on agglutination of tubercle bacilli so far as its practical application is concerned, may be summarized in the statement that the agglutination of tubercle bacilli does not occur constantly or regularly in tuberculosis. Consequently the reaction, at the present time at any rate, does not constitute a practicable, available diagnostic measure. This is the conclusion of Thellung,[1] who has studied the question quite extensively and also experimentally. He finds that the subcutaneous injection of Koch's bacillary emulsion in doses of a few milligrams leads to the development of substances in the blood serum of the guinea-pig that agglutinate tubercle bacilli more markedly than the serum of non-tuberculous animals. The agglutinating power is produced with difficulty in the case of rabbits. At the same time, Thellung made the observation that Koch's new tuberculin did not have a favorable influence on the course of experimental tuberculosis in guinea-pigs and rabbits. This new tuberculin consists of an emulsion of dead bacilli. It is of interest, further, to note that two guinea-pigs injected with ground bacilli, such as are furnished by the Höchst Company, died from tuberculosis, and that of two guinea-pigs injected with

---

[1] American Journal of Insanity, lix, 1, July, 1902, p. 17.

[1] Centralbl. f. Bact., 1902, xxxii, 28-48.

Koch's new tuberculin (bacillary emulsion) also furnished by the Höchst Company, one became tuberculous. Hence, both these preparations contained viable tubercle bacilli virulent for guinea-pigs. Now, if such preparations give rise to tuberculosis in guinea-pigs they may just as well give rise to tuberculosis in human bodies when injected. Certainly manufacturers of preparations of this kind must be able to guarantee their non-infectiousness if they desire the confidence of physicians.

CHROMOPHILE CELLS AND CHROMOPHILE ORGANS.

There occur in various parts of the body peculiar cells. often aggregated into small nodules, which for some time have attracted much attention, notably from histologists. These cells are characterized especially by the fact that they assume a brown color in solutions of chromic acid and its salts. These structures occur mostly in the regions through which passes the sympathetic nervous system, and in many cases they are connected with the sympathetic nerves. They differ from sympathetic ganglia as ordinarily understood because of the preponderance of cellular elements. The so-called carotid gland and the medullary substance of the adrenals consist, to a large extent at least, of chromophile cells.

In a recent article Alfred Kohn[1] gives these mysterious cells and organs a comprehensive consideration, reviewing their occurrence in various parts of the body in different kinds of mammals, reptiles. birds, etc., in all of which they occur with marked regularity. Because of their similarity to ganglia he calls them also paraganglia. He reaches the conclusion that they are derived from the embryonal *Anlagen* of the sympathetic ganglia, the cells early acquiring their affinity for chrome salts. When in the form of small nodules and flattened bands they constitute often independent structures, generally located in a plexus of the sympathetic, but there also occur single cells and smaller masses deposited in sympathetic ganglia and nerves, and the chromophile cells in the medullary substance of the adrenals of higher vertebrates he also regards as of the same nature and origin. So far as has been determined, extracts from these chromophile organs have the power, when introduced into the circulatory system. of greatly raising the blood pressure, as has been shown repeatedly in the case of the adrenals, and by Biedl and Wiesel for the carotid gland or paraganglion intercaroticum. This is virtually all that is as yet known in regard to the physiology of these structures. The affinity for chrome salts may be of importance in the recognition of tumors arising from Kohn's paraganglia. This has been demonstrated already in one instance by Stangl.

CRIMINAL ABORTION.

It is unfortunately too common an event for the physician to have to do in some way or other with criminal abortion. He may be directly asked to commit or to assist the crime for one of his patients. He may, if unwary, be led to do something unwittingly that may aid it, or he may be entrapped into a situation that puts him in a decidedly bad light before the law, though actually innocent of any real wrongdoing. Many young physicians and some older ones, from lack of knowledge or of due precautions, have found themselves in situations, the possible outcomes of which were not quite pleasant to contemplate. If the patient did well, all was right, but if not, very serious charges might result and all without any real crime or evil intent. In the July issue of the *Medical Critic,* Dr. Frederick Griffith writes on this theme, giving some aptly illustrative cases in his experience. He endorses Dr Barton Cook Hirst's recommendation that the physician, when called in to a case where an abortion has been performed, refuse all responsibility for the patient unless a confession exonerating him from any connection with the crime is given, signed by the patient and the signature duly witnessed by one or more persons. If the woman recovers, this evidence may be destroyed—though for the physician's safety it might perhaps be better to preserve it—but if death is imminent the confession can be forwarded to the district attorney without delay. This, according to legal opinion obtained, would establish the physician's freedom from complicity or criminal intention in Pennsylvania and probably elsewhere. This is a simple enough precaution, and it would also be well for the young physician in such a case to have the counsel of some more experienced practitioner. Abortion is a crime that seldom comes to light except where followed by disaster, and there is danger where this occurs; as Dr. Griffith says, "the law is anxious to reach offenders of this sort, but has but a short arm, which falls upon the innocent physician, who. careless of personal interest, allows circumstances to work against him." Any one who accepts the responsibility for these patients must, as he says, "be as wise as a serpent and harmless as a dove," for there is hardly any class of cases that come under a physician's care that present more ticklish problems to try his worldly wisdom and his professional *morale.*

SEROTHERAPY IN CANCER.

Whatever promises to be even a palliative in the treatment of cancer is worthy of the attention of the therapeutist. Especially is this the case if the agency or procedure is along the lines that have been successfully followed in other disorders, though as yet untried or unsuccessful in the management of malignant growths. The suggestion of serotherapy of cancer is a very natural one. but hitherto nothing really encouraging has resulted from experiment. Jensen, it is true, had noticed modification in cancer growth in mice, shriveling and suppuration of the tumor following serum injections from cancer tissue. but nothing that seemed significant enough to warrant any strong expectations of good results in actual therapeutics. Very recently, however, Von Leyden and Blumenthal have carried their research further and report[1] actual beneficial effects on human patients. They first experimented on cancerous dogs, using serum expressed from other cancerous growths on the same species, and cultivated through rabbits, and produced softening and liquefaction of the growth, and later, on another dog, with direct injections of the canine cancer extract with still better results, the tumor dwindling down to a mere relic of its former self after two months' treatment. This was extirpated and its cancerous nature verified by the microscope. These encouraging results led them to experiment still further on human subjects. They employed an extract obtained by crushing and compression from a freshly removed human cancer on three patients, having first determined the harmlessness of the injections on dogs. In one case of carcinoma of the bladder and urethra of many months' duration, the patient bore the injections well, the urinary functions improved, the conditions became more comfortable generally, and the cancer cells also disappeared almost entirely from the urine. The patient died suddenly from heart disease and at the autopsy it was found that the tumor had been reduced from the size of an apple to some insignificant lumps and the previously existing swelling and infiltration of the inguinal glands had entirely disappeared. There were no metastases. Another patient, with uterine carcinoma under observation, has greatly improved in general condition, the pains have diminished and gradually disappeared. These results, imperfect as they are, are encouraging and indicate that we have possibly a still further remedial resource for this dreaded disease. As the authors say, more time and observation are needed before anything definite can be claimed, and this line of research deserves still further development.

---

Medical News.

ALABAMA.

Birmingham Medical College has nearly completed the new building and will be ready to receive students at the opening of the college year, October 1.

Infirmary Almost Ready.—The New Providence Infirmary, Mobile, which has been erected at a cost of about $100,000 and has been constructed in accordance with the most advanced hygienic ideas, is almost ready to receive patients.

Personal.—Dr. Nicholas D. Richardson, Athens, has received an appointment in the U. S. Public Health and Marine-Hospital Service and will be stationed at Angel Island, Cal. ——Dr. Arthur M. Brown, Birmingham, was given a banquet by prominent local colored citizens and physicians, August 26. He has located in Chicago for practice.

Florence Healthy.—On account of reports circulated through the northern part of the state that typhoid fever and other diseases were epidemic in Florence, an investigation was ordered by the authorities. The health officer reports the rumors false, and that there is only one case of typhoid fever in the city, and furthermore that that case was imported.

CALIFORNIA.

Hospital Donation.—Drs. A. J. Comstock, Jr., Thomas E. Cunnane, Frederic H. Huning, Ventura, and Dr. John P. Hinckley, Fillmore, have donated an *x*-ray and static apparatus to the Elizabeth Bard Memorial Hospital, Ventura.

Personal.—Dr. Elmer E. Stone, San Francisco, chief inspector of the State Board of Health of California, has been elected superintendent of the Napa State Hospital for the Insane, vice Dr. Alden M. Gardner.——Dr. Howard Morrow, San Francisco, has been appointed city bacteriologist, vice Dr. Wilfred H. Kellogg, resigned.

Recrudescence of Plague.—The plague situation at San Francisco is becoming more alarming. In August seven fatal cases of the disease were officially reported, five more of which occurred since the 18th. The autopsies are made at the United States Oriental Laboratory, maintained in San Francisco by the Marine-Hospital Service for the express purpose of testing cases of bubonic plague.

Oakland Medical College Opens.—The Oakland College of Medicine and Surgery opened for work September 15. The new building had been previously thrown open for informal inspection. The officers and directors of the new institution are: Dr. Frank L. Adams, president; Dr. Carl R. Krone, secretary; Dr. Hayward G. Thomas, treasurer, and Drs. Dennis D. Crowley and Edward N. Ewer, directors.

ILLINOIS.

Hospital Incorporated.—The Beth Saida Hospital at Decatur has been incorporated, without capital and not for profit.

Typhoid in McDonough County.—The Macomb Board of Health has investigated the prevalence of typhoid fever in McDonough County and reports 73 cases so far this season, with new cases developing daily. Of these 36, or nearly 50 per cent., occurred in Macomb.

New Hospital for Pontiac.—Dr. John A. Colbourne, Ransom, formerly of Pontiac, proposes to erect a hospital building to cost from $8000 to $10,000, on land owned by him in Pontiac, subject to the following provisions: That the people of Pontiac furnish $5000 for the furnishings and equipment of the institution, and that the hospital be open to all practitioners in good standing.

Black-List in Rock Island and Moline.—The physicians of Moline held another meeting, September 9, to complete their plans for the compiling of a black-list. Nearly all present submitted lists of people they considered dead-beats, and the others are to hand in their lists soon. These names will be arranged in proper form and each physician in Moline and Rock Island will be furnished a copy.

Chicago.

The Chicago Eye, Ear, Nose and Throat Hospital has recently equipped its building with a steel fire-escape of the stairway pattern, which is also connected by steel balconies with each sleeping room in the building.

Thousands for Charity.—The will of Oscar Rosenthal, filed September 13, gives Michael Reese Hospital, Alexian Brothers' Hospital, Chicago Home for Incurables, and National Jewish Hospital for Consumptives, each $1500, and $7500 to the United Hebrew Charities.

Mortality for the Week.—The total number of deaths for the week ended September 13 was 494, equivalent to an annual death rate of 14.13 per 1000. This compares favorably with the death rate for the previous week, 15 per 1000, and with that for the corresponding week of 1901, 14.74 per 1000.

Return to Work.—Dr. R. D. MacArthur and family, from Old Orchard Beach, Maine.——Dr. and Mrs. Joseph Warsall, from Europe.——Drs. L. L. McArthur, Frank Billings, R. H. Harvey and Henry P. Newman, from a lake trip.——Dr. Paull Marquis, from Watch Hill, R. I.——Dr. Charles G. Davis, from Waunita Hot Springs, Colo.——Dr. E. Fletcher Ingals and family, and Dr. Otto T. Freer, from a trip to Colorado and the West.——Dr. and Mrs. J. Nevins Hyde, from Maine.——Dr. and Mrs. William Cuthbertson, from California and the Canadian Rockies.——Dr. E. C. Dudley, from Japan.

Typhoid on the Wane.—At the close of the week there were gratifying indications that the typhoid fever epidemic was abating. The total typhoid deaths reported—43—were 12 less than those for the previous week, and during the last three days of the week there were only five, one and two, respectively, or a daily average of less than three, as compared with a previous daily average of seven for the six weeks previous. This decrease in the number of deaths, as an indication of the decline of the epidemic, was further corroborated by the returns of cases admitted to the various hospitals. In the County Hospital there were only 240 cases under treatment at the close of the week as compared with 373 the week previous—a reduction of 35 per cent. The decrease in typhoid mortality can not be attributed to improvement in the water supply; it is due rather to the campaign of education begun by the Department of Health nearly two months ago as to the nature and cause of typhoid and the method of its prevention. Another indication that the height of the epidemic has been reached, is the increasing duration of the disease in the fatal cases. The average duration of the sickness in the fatal cases in August was 17 days. During the first 13 days of September it was 22 days, and during the last week it was more than 27 days. As the average period of the incubation of the disease after infection with the poison is two weeks these latter figures show that the infection occurred at least 41 days previous, or in the latter part of July, when the water supply was badly polluted.

INDIANA.

College to Occupy New Building.—The Central College of Physicians and Surgeons, Indianapolis, will open for its twenty-sixth annual session October 1, in its new building, which has been erected at a cost of $70,000.

Plan Methodist State Hospital.—The plans for a Methodist state hospital and deaconess home have now assumed definite shape. Up to September 12 $60,000 had been subscribed toward the project. Work will start when $100,000 has been secured, and it is confidently believed this sum will be available by Jan. 1, 1903.

Insane Hospital Dedicated.—The new hospital for the sick insane connected with the Central Indiana Hospital for the Insane, Indianapolis, erected at a cost of $110,000, was formally dedicated September 9. The building will accommodate 100 patients. Addresses were made by the Governor and by Drs. William B. Fletcher, Henry Jameson, Allison Maxwell, Patrick H. Jameson, and by the superintendent, Dr. George F. Edenharter.

Personal.—Dr. Hannah M. Graham, Indianapolis, has returned after a course of study in European hospitals.——Dr. Myron A. Boor has been appointed police surgeon and Dr. Malachi R. Combs secretary of the board of health of Terre Haute.——Dr. Charles Marvel, Richmond, has returned after several months spent in study abroad.——Dr. Frederick T. Hiner, West Lafayette, has been elected health officer of Tippecanoe County.

IOWA.

Patients Transferred.—The Iowa Hospital for the Insane, Mount Pleasant, has transferred 121 patients to the state hospital at Clarinda.

Medical College Opens.—The Sioux City College of Medicine began its thirteenth year September 10, with a freshman class of about 30.

Merger Against Dead-Beats.—The physicians of Maquoketa have entered into a combination to protect themselves against dead-beats. The patients who do not pay bills will be booked, and the physicians announce that none of them will answer a call from these unless the fee be paid in advance.

Personal.—Dr. Aram G. Hejinian and family of Anamosa sail to-day for Europe. He will do post-graduate work six months. On his return he intends to visit Egypt, Palestine and other points of interest.——Dr. J. W. Benadom, Maquoketa, was waylaid, beaten and robbed of $42, while walking near Maquoketa, August 22.

New Medical Board for Morbonia Hospital.—A medical board for Morbonia Hospital, Davenport, has been organized with the following officers and staff: President, Dr. Andrew W. Bowman; vice-president, Dr. Lee Weber; secretary, Dr. John D. Cantwell; surgical staff—Drs. Jennings P. Crawford, Edward S. Bowman, Alfred B. Hender, Frank N. Stiles and Frank E. Rudolph; medical staff—Drs. Frederick Lambach, Gustavus Hoepfner, F. J. Starbuck, Clarence T. Lindley and William F. Turner; special staff—Drs. Lee Weber and Karl Vollmer.

KENTUCKY.

In Charge of Eruptive Hospital.—Dr. Jesse I. Whittenberg has assumed charge of the Eruptive Hospital, Louisville, vice Dr. J. Brent Palmer, deceased.

Typhoid Fever Raging.—Advices from Owingsville are that typhoid fever is increasing rapidly and is of a severe type. It is estimated that there are more than 300 cases in Bath County.

To Collect Bills.—Articles of incorporation have been filed by the Doctors' Protective Association of Kentucky. The object of the association is to collect and purchase accounts, and to furnish information to physicians regarding the solvency of their debtors.

A Grateful Patient.—In testimony of Mr. Ben F. Mitchell's appreciation of the interest taken in his case by the Louisville Society of Medicine, he gave a dinner to the members of the society at his residence, September 3, at which Dr. Walker B. Gossett officiated as toastmaster.

MARYLAND.

Baltimore Deaths.—The deaths in Baltimore for the week ended September 13 were 191. Nine deaths and 81 new cases of typhoid fever were reported.

Typhoid in Maryland.—The great prevalence of typhoid fever throughout the state is attracting attention and the secretary of the State Board of Health has received requests from all over the state to inspect and analyze drinking water.

Class in X-Ray Treatment of Cancer.—Early in October a class will be organized at the Baltimore Medical College, of which the Maryland General Hospital is an auxiliary, for the study of the *x*-ray treatment. It will be conducted by Dr. Henry F. Cassidy and Dr. Francis Carey.

Baltimore Personals.—Dr. Page Edmunds is convalescing at Atlantic City from an attack of typhoid fever.——Dr. William H. Welch sailed September 18 for London, where he will deliver the Huxley Lecture at the Charing Cross Medical School.——Dr. Herbert Richardson has sailed for Jamaica.——Drs. Rufus J. Cole and Louis M. Warfield sailed for Bremen September 11.——Dr. Frederick Baetjer has started for Europe to study the *x*-ray treatment of cancer.——Dr. W. Meyers Garrison has been appointed fifth assistant physician at the New Jersey State Hospital, Morris Plains.

MASSACHUSETTS.

Nurses on Strike.—Of the 35 trained nurses employed at the Worcester Insane Asylum 24 have struck for shorter hours and because they did not like the treatment accorded them by Superintendent Hosea M. Quimby. They complain of overwork, neglect of patients and bad food.

Out-Patient Department of Mount Sinai Hospital.—This department was formally opened August 4 by the Mount Sinai Hospital Society, whose purpose is to minister to the sick among its people who can not or will not be treated by the existing institutions on account of racial and religious differences, or for the lack of knowledge of the English language. On the medical board are Drs. Charles G. Cumston, Nathan M. Goodman, Henry Ehrlich, L. Bernard Lechersack and S. Meyers.

Personals.—Dr. Alonzo L. Stickney, after 31 years of practice in Ashburnham, has moved to Cambridge.——Dr. Arthur McCabe, city physician and chairman of the board of health of Boston, has resigned and will travel for a year abroad, and also pursue studies in his specialty.——Dr. James W. Holland, acting assistant surgeon, U. S. Army, has returned from the Philippines and will reopen an office in Huntington.——Dr. and Mrs. George J. Engelmann, Boston, are in Rome and will not return until November.

The Care of Consumptives.—The State Board of Charity has sent the following questions to the several medical societies of the state and invites their replies:

> Is it necessary or expedient for the Commonwealth to make additional provision for the care and treatment of consumptives? If so, should such provision be made by establishing one large new sanatorium, or by establishing several smaller institutions; and, if several, should these be located in different parts of the Commonwealth, so as to provide for patients at sanatoriums comparatively near their places of residence?

Last year 1149 new cases of consumption were reported to the Boston Board of Health. Thus far this year 661 cases have been found, which is a decrease from the number for the corresponding period a year ago. The city has no hospital to which to remove this class of patients, many of whom really need better care than can be given to them in their own homes, which are disinfected on the removal of patients.

NEW JERSEY.

Personal.—Dr. Elmer H. Rogers, Trenton, has gone to London for a course of post-graduate study in medicine.——Dr. Daniel B. McCartie, Newark, as the result of a runaway accident, is in hospital with a dislocated shoulder and other injuries.——Dr. Frank Hosford, Newark, has been appointed assistant physician at the State Hospital at Morris Plains.

For Jersey City Hospital.—Cornelius Zabriskie, a banker of Jersey City, whose home is in Hackensack, has offered to give $150,000 toward building a new city hospital on condition that residents of Jersey City shall raise a like amount by subscription. He also makes it a condition that politics shall be kept out of the hospital management. Dr. John D. McGill of the health board says he will give $25,000 toward the public subscriptions.

Consumption Sanatorium Closed.—The sudden and unceremonious closing of the Sanatorium for Consumptives, opened by Mrs. Louis Horlacker at Morristown about a year ago, which forced the patients to seek shelter with the neighbors, and the proprietor's mysterious disappearance have caused much uneasiness among the local members of the board of health, because the existence of the institution was permitted against the protest of many citizens and the provisions of the health code.

State Home for Consumptives to be at Glen Gardner.—After months spent in searching for a suitable location the board of managers of the New Jersey State Sanatorium for Tuberculous Diseases has selected a site, and will, if the Governor approves their selection, purchase the ground and begin operations just as soon as title can be given for the tract The site selected, half a mile from Glen Gardner, Hunterdon County, includes nearly 500 acres of land, fully 950 feet above tide water, a considerable part of the land being thickly wooded The air is pure and the soil dry There is an abundance of pure water on the place Part of the tract can be used as a dairy farm The place where the buildings will be erected is sheltered from the winds The site is in a secluded place, in the upper part of Hunterdon County, yet easy of access The commission was appointed by Governor Murphy last spring under authority conferred by an act of the legislature, passed at the instance of the executive, in the closing hours of the session An initial appropriation of $50 000 was made The members of the commission are Dr Charles J Kipp, Newark, president, Dr Austin Scott, president of Rutgers College, Colonel E A Stevens Castle Point, Hoboken, Dr Obadiah H Sproul, Flemington Dr Elmer Barwis, Trenton, Dr James S Green, Elizabeth, Colonel Frank L Shepard, Elberon and Dr William S Jones Camden

NEW YORK.

Buffalo Personals.—Dr A W Bayliss and wife, who have been spending five months abroad, returned September 18——Dr and Mrs Bernard Barton returned to town from Wauakah——Dr and Mrs Herman Mynter sailed from abroad September 18 on the *Pretoria*

Stony Wold Sanitarium.—The cornerstone of the Stony Wold Sanitarium, at Lake Kushaqua in the Adirondacks, was laid with appropriate ceremonies, September 11 Under the auspices of Mrs George F Shrady a committee of one hundred women was formed to raise a fund of $100,000 for a sanitarium for consumptive working girls in the Adirondacks Mrs Seth Low and a large number of New York's leading society women were included in the list The property includes a camp and some outbuildings that have been put to use, and already a number of patients who have been supported during the hot months by individual members are enjoying the benefit of the institution One of the leaders in this good work is the wife of Dr James E Newcomb

Cornell University Medical Department.—In the issue of September 6 the statement that the new medical building of Cornell University is about to be ready for occupancy this fall applies to the Cornell building at Ithaca and not at New York City The university gives the full four years of the medical course in a separate department in New York City and it also duplicates the first two years of this course at Ithaca so as to permit students taking the arts course (degree of A B) to elect medical studies The elective system in the college is so arranged that students can obtain a good deal of the second year work of the medical school before leaving the academic department and although a student only obtains one year of credit in the medical school for this work, he is allowed electives in clinical work which give him a great advantage over the students pursuing the ordinary curriculum This is an interesting experiment in permitting practical medical electives The New York City Department has occupied its present quarters for two years and is thoroughly well established

New York City.

Bequest to German Hospital—The German Hospital has received $5000, bequeathed to it by the late John Keller

Contagion in the Schools—Through the labors of the health department over 1500 children have been debarred from the public schools of Brooklyn, chiefly because of contagious ophthalmia and parasitic diseases of the scalp

Equine Eddyism—The latest reported victory of Eddyism over disease is reported to be the wonderful restoration to health and activity of a noted racing stallion, scheduled to race next week Commenting on this, one trainer sagely remarked "It's better to nerve the beast than give him a drop of rye"

A New Bellevue Hospital Demanded—The recent report of the trustees of Bellevue Hospital makes public what has long been only too familiar to the medical profession in the city namely, that despite all that has been and can be done toward improving the present ramshackle building now known as Bellevue Hospital it will remain unsanitary and wholly unsuitable for carrying on its great work As the work of the hospital can not be interrupted, the new buildings must be erected in sections and the mayor is urged to take the first steps at once

Ambulance Surgeons.—The frequent blunders of ambulance surgeons chronicled in the daily papers emphasize the necessity of having men of riper experience in this important and trying branch of hospital service The need for this has long been recognized by those conversant with hospital work, and it is, therefore, a pleasure to note that by a new rule, which has been adopted by Bellevue, Roosevelt, the Presbyterian and the New York hospitals, no surgical interne is allowed to do ambulance duty until he has served at least six months in the hospital

More Hospitals for Contagious Diseases—Mayor Low has practically pledged his administration to increase the hospital accommodations for contagious diseases, and has expressed the opinion that to do this properly will call for the expenditure of $2,000,000 in the next three years Comparing New York and London, he stated that only 9 5 per cent of cases of such diseases were treated in hospitals in New York as against 88 per cent in London It is reassuring to learn that every pavilion of the city smallpox hospital has been renovated better accommodations provided for the convalescents, and telephones installed so that it will in the future be easy for anxious friends and relatives to obtain information concerning the condition of the patients

Personal.—Dr William H Bates, well known because of his connection with the introduction of suprarenal extract to the profession has been missing from his home since August 30 On that day he left the house, saying that he was going out of town for two or three days Nothing has been heard from him since then, and his wife being at the time in the Adirondacks the police were not notified until September 12——Long study on the problem of compounding an elixir that shall enable man to live forever has driven Dr Lorenzo J Kohnstamm insane His mind, which had been tottering for some time, has given way, and he is now a patient in the insane pavilion at Bellevue——Dr E Grant Dilworth living in a sparsely settled portion of the Borough of the Bronx, was assaulted by highwaymen but was fortunately able to make his escape

Increase in Typhoid—The report of the Health Commissioner for the week ended September 6 shows an unusual prevalence of typhoid fever For the week the number of cases reported was 219, compared with 204 for the previous week and 119 for the week before The number of typhoid cases this year enormously exceeds the figures of those of previous years, the number for the same weeks in the last two years being 83 and 114 in 1901 and 88 and 53 in 1900 How great the increase in typhoid is this summer can best be gathered from the comparison of the figures of the last month with those of the same month of the last two years The total of the last month of this year aggregates 646 For 1901 the figure was 257 and for 1900 248 In explanation of this rather striking circumstance the health department officials say that, while there is a certain increase in the number of typhoid victims this year, a considerable portion of this number are due to the increased facilities for detecting the existence of the disease Moreover, there has been an unusual number of cases which on investigation proved to be falsely reported As yet there has been no apparent increase in the number of deaths from typhoid

OHIO.

Hospital Incorporated—Niles City Hospital has been incorporated by Drs Curtis C Williams, Henry V Ormerod, Charles T Swaney and others, with a capital stock of $10,000

Municipal Health Departments Favored.—The Columbus Academy of Medicine favors a department of health for every municipality in Ohio, and has named a committee to recommend the plan to the legislature Boards of health, as advocated by the academy, will be uniform in all cities and will be composed of five members, elected for five years one member retiring each year

Personal—Dr William H Rothert Cincinnati, has been appointed assistant surgeon, Ohio National Guard, with rank of captain——Dr Arthur E Evans, Columbus, has been elected to the chair of obstetrics in the Ohio Medical University, vice Dr James U Barnhill, promoted to the chair of surgery and clinical surgery——Dr Webb J Kelly, Piqua, has been appointed division surgeon of the Western Ohio Railway

PENNSYLVANIA

Personal—Dr M R Coates, McKeesport received severe injuries in a runaway accident recently which necessitated treatment at the city hospital——Dr A W Sherrill, Crafton has been appointed first assistant resident physician at the city home and hospitals Marshalsea

Charter Refused "Natural Healers."—The application for a charter for the Sheppard School of Natural Healing, Pittsburg, has been refused by Common Pleas Court No. 2. The institution had a capital stock of $25,000, and was formed "to conduct a place for the care of sick and disabled persons and for the inculcation of the principle of natural healing."

Marine Hospital at Pittsburg.—Bids for a site for the Marine Hospital which Congress has authorized in Pittsburg were recently opened at the Treasury in Washington. As the maximum expenditure for site and buildings is $125,000, most of the bids are too high for consideration. The specifications prescribed that the plat of ground should not be less than one acre nor more than four acres. Surgeon-General Wyman expresses his belief in the great need of such a hospital in Pittsburg, where rivermen having served two months or more may be treated at the expense of the government. Many of these men now have to be sent for treatment to the Marine Hospital at Cincinnati.

Philadelphia.

To Decline Re-election as Dean.—It is stated on good authority that Dr. John Marshall, professor of chemistry and toxicology and dean of the faculty of medicine in the University of Pennsylvania, will refuse re-election as dean for the coming year. Dr. Marshall wishes to be free to devote all his time and energy to the subjects of his department.

Typhoid Fever Increasing.—In the two weeks ended September 6, 256 new cases of typhoid fever were reported to the Bureau of Health. The number of new cases has been increasing weekly since the early part of August. An investigation made by Assistant Medical Inspector Dr. Thomas J. Beatty showed that quite a large number of cases now under treatment in the city contracted the disease while the subjects were on vacation in the country, at Atlantic City and other summer resorts.

Personal.—Dr. Hannah T. Croasdale has resigned from the Woman's Medical College of Pennsylvania, where she has been for thirty years professor of gynecology. Her successor will be Dr. Ella B. Everitt, who for the last six years has been chief resident and operating physician at the Woman's Hospital of Philadelphia. Dr. Everitt is succeeded by Dr. Alice Seabrooke, of the Methodist Hospital.——Dr. Edith W. Cadwalader, of the Woman's Hospital, will go to Paris to pursue special studies.——Dr. John Marshall is visiting Dr. George A. Piersoll, professor of anatomy in the University of Pennsylvania, at Merion, Mass.——Dr. Joseph McFarland has gone on a trip to Europe.

Hospital Bequests.—Miss Harriet S. Benson, noted for her numerous benefactions during life, left as bequests to charity much of her estate, worth perhaps more than $2,000,000. The institutions mentioned are but a small proportion of those to profit by her will. The following receive bequests of $10,000 each: The Orthopedic Hospital; the Children's Hospital; the Philadelphia Home for Infants; the Homeopathic Hospital; the Home for Incurables, and the Bethesda Children's Christian Home. Bequests of $500 each were made to the following: Pennsylvania Hospital; Philadelphia Polyclinic and College for Graduates in Medicine; Medico-Chirurgical College and Hospital; Wills Eye Hospital; Hahnemann Medical College; Women's Hospital; Gynecean Hospital; Maternity Hospital, Howard Hospital and Infirmary; Sheltering Arms; Midnight Mission; Children's Country Week Association, all of Philadelphia. Seaside Home for Invalid Women and Children's Seashore Home at Atlantic City; and Pennsylvania Training School for Feeble-Minded Children, Media, Pa.

GENERAL.

Essays on Preventive Medicine.—The Maltine Company announces that two hundred and eight essays on "Preventive Medicine" have been entered in competition for the two cash prizes.

Cholera in the Philippines continues at the rate of about ninety deaths daily. There were four cases of cholera and three deaths from that disease on the U. S. transport *Sherman* between Manila, which she left September 1 bound for San Francisco, and Nagasaki, Japan, where she arrived September 10. She has been quarantined at Nagasaki. A later cablegram announces that six more cases have developed and another death has occurred, all among enlisted men. The total cases unofficially estimated to have occurred in the islands up to September 16 are 59,759 cases and 41,804 deaths. Since September 1, 9 soldiers have been among the number dead from cholera.

Volunteer Surgeons to be Released.—A large number of volunteers are to be mustered out, as previously noted in The Journal. Among the reasons for this are the improvement in sanitary conditions, the more thorough acclimatization of the soldiers in the Philippines, and the cessation of hostilities in the islands. With the establishment of peace, about 400 outside stations are being abandoned. The principal cause of the increase of the medical staff was to provide for the maintenance of a large number of stations in the Philippines. At the same time, there are many vacancies in the regular army and examinations are being held frequently to test candidates for these positions.

Field Hospital Practice.—An important feature of the army maneuvers at Fort Riley, Kas., will be the arrangements which have been made for the medical department's equipment. A dispensary and hospital will be provided for each regiment, and a field hospital of 108 beds will be established for the command. The post hospital at Fort Riley will serve as a base hospital. A field hospital organized in accordance with the new regulations of the medical department is such that it can be readily divided into three parts of thirty-six beds each, and it is likely that in the present instance, when the period of hostilities commences at Fort Riley, this hospital will be divided between the opposing forces, one to have a hospital of thirty-six beds and the other one of seventy-two beds. Lieut.-Col. John Van R. Hoff, deputy surgeon general, will have charge of the medical department at the maneuvers.

Location and Its Bearing on Life Insurance.—In the medical section of the National Fraternal Congress at Denver, August 26, the question was discussed whether or not the geographical location of the person insured should change the rate to be charged. The basis of the question is the widely varying mortality rate in different localities. A committee's investigations were embodied in the report prepared by Dr. Ira W. Porter of Omaha. The average death rate for the orders for the last current year was 5.03. The mortality rate of the states shows Washington to have the lowest; its rate being 1.3. Nevada has the highest with a rate of 17. The rate for Colorado is 4.7. After arranging the states into groups the northwestern group which includes the states from Colorado to the north, has an average of 3.75, and the southwestern groups including those south of the previous group, has a rate of 2.3. The southeastern division including Florida, Alabama and other southeastern states, has the highest rate, it being 8.5. In closing Dr. Porter says: "The conclusions to be drawn from this paper I leave to you. I am more firmly of the opinion that location is an element of hazard just as much as is occupation, and that the applicant should pay for the risk assumed. In what manner this shall be I leave to the actuaries."

Brig.-Gen. Robert M. O'Reilly, who was appointed by the President surgeon general several weeks ago in anticipation of General Forwood's retirement, has relieved Brig.-Gen. William H. Forwood of his duties at the head of the medical department of the Army. General O'Reilly was recently chief surgeon of the Department of California. He will have until January, 1909, to serve as surgeon general. He was graduated from the medical department of the University of Pennsylvania, and entered the regular Army in August, 1862, as an acting medical cadet. He was appointed a medical cadet in 1864. In April, 1867, he was appointed assistant surgeon, with the rank of first lieutenant. He saw much field duty in the Indian country during the next six years. In the Sioux expedition of March, 1874, he was the chief surgeon. In June, 1875, he came east, serving successively at Fort McHenry, Md.; Fort Hamilton, N. Y.; Fort Ontario, N. Y.; Charleston, S. C., and Atlanta, Ga., and was with the troops in Pennsylvania and Maryland during the serious labor troubles of 1877. He was the attending physician to President and Mrs. Cleveland during a part of Mr. Cleveland's first term and throughout his second administration, coming to Washington in June, 1882, for duty in the office of the surgeon general, becoming in 1884 the attending surgeon. While assigned away from Washington he was with the troops in the field against the Sioux in South Dakota in the early winter of 1890. At the outbreak of the Spanish war he was appointed lieutenant colonel and chief surgeon of Volunteers. He was successively chief surgeon of the First Independent Division and of the Fourth Army Corps, at Tampa, Fla. He was also chief surgeon of the division of Cuba for a time.

FOREIGN.

German Physician Surgeon-General of Siamese Army.—Dr. T. Trumpp has been appointed by the King of Siam chief of the medical department of his army.

Lannelongue Prize.—Professor Lannelongue of Paris has presented 38,000 francs, about $7600, to the Paris Académie de Médecine for the endowment of a triennial prize.

Seventieth Professional Anniversary.—The friends of Dr. Jacobs of Cologne recently assembled to honor his seventieth "doctor-jubiläum" and his ninety-third birthday.

Marriage Bill in France.—A bill has been introduced into the House of Deputies in France proposing to exact from male and female candidates for matrimony medical certificates that they are fit to be parents.

Another Conviction of a Charlatan in Germany.—The Hanover courts have condemned to a fine of 100 marks or ten days' imprisonment, the charlatan Zwicker on account of unwarranted promises of complete cure of incurable diseases in his advertisements.

Increase of Insanity in London.—The lunacy statistics of the administrative county of London show an increase of 50 per cent. in the last ten years, the total number of lunatics being 21,369 in a population of 4,536,541. Drink and business and domestic troubles were accounted to be largely responsible.

Honors to the Memory of Pasteur.—A fine portrait statue of Pasteur has been erected at Dôle, his birthplace, and a committee has been appointed to raise funds to purchase the house in which he was born, as a permanent memorial. Besançon has also recently dedicated a bust of Pasteur as a memorial of the three years he spent there as pupil and then teacher in the lycee.

Art Prize for Richer.—The Paris Académie des Beaux-Arts recently conferred the Joest prize of $400 on Dr. Paul Richer, member of the Académie de Médecine, for his great literary work, "L'Art et la Médecine." Extracts from this work have been published from time to time in the "Nouvelle Iconographie de la Salpétrière," with the corresponding wealth of illustrations.

Precautions Against Cholera in Europe.—The cholera commission of Germany has been holding a special meeting at Berlin to discuss ways and means to ward off infection from the dangerous foci in Egypt and elsewhere. The Russian government has recently sent a large number of military surgeons to its eastern departments to co-operate in preventing the spread of cholera.

Foodstuffs Treated with Boric Acid Excluded from Peru.—The authorities of Peru have issued a decree forbidding the importation of foodstuffs to which boric acid has been added for a preservative. The decree was based on the testimony of the medical faculty of Lima and on the investigations of Dr. Rinehart of Kentucky, according to a communication in the *Allg. Med. Ct.-Ztg.*

New Medical Periodicals.—The publishing house of Gustav Fisher of Jena announces two new journals, the *Zeitschrift f. allg. Physiologie*, issued by Professor M. Verworn of Göttingen, and the *Archiv für Protistenkunde*, issued by Dr. F. Schaudinn of Rovigno. The price of each is 24 marks a volume. "Protistenkunde" means the science of the first forms of living matter.

Non-Conviction of a Charlatan for Fatal Practices.—The court at Flensburg recently acquitted a charlatan who had bled a pregnant woman and had thus induced fatal blood poisoning by the entire lack of aseptic precautions. His defense was that he made no charge for bleeding persons and merely did it occasionally to oblige his friends, not oftener than five or six times a year.

Fraudulent American Dental Diplomas in Germany.—The *Allg. Med. Ct.-Ztg.* states th[illegible] been instituted against 54 American [illegible] several women), now practicing in Germany, who claim to have received diplomas from the "German-American Dental College, Chicago," and the "Cosmopolitan Post-graduate Dental College." These institutions, it adds, are notorious frauds, selling their diplomas to anyone.

Deaths Abroad.—Dr. M. Skjelderup died at Christiania, Aug. 21. He was ex-professor of therapeutics and one of the founders of the local medical journal, now the *Tidsskrift f. d. Norske Laegenf.* Other deaths reported are those of Dr. von Tappeiner of Meran in his eighty-seventh year, prominent in anthropology as well as in medical research. He suggested before Koch the transmissibility of tuberculosis by inhalation.——Dr. Schlesinger of Berlin, and Dr. Pasternazki, professor of internal medicine at St. Petersburg.

Fine for a Physician in Stettin.—A physician at Stettin gave a patient an order for 1 gm. of cocain which he was to buy at the druggist's and bring the next day to the physician who was to dissolve it and inject it as a local analgesic. The patient misunderstood the directions and drank the cocain, with resulting severe intoxication, until relieved by the stomach pump. The patient sued the physician for damages, and although the latter protested that he had given most explicit directions, he was condemned to pay nearly $25, as the court decided that he had not exercised due caution in the matter.

Steffan Does Not Get Back His Fee for His Rejected Title.—The Journal mentioned at the time the circumstances connected with the refusal of Dr. Steffan, the well-known ophthalmologist of Frankfurt, to pay the customary fee of $75 when the honorary title of Sanitäte-Rath was conferred on him. He at last paid the fee, but under protest, stating that he had no wish for the title. It was later withdrawn, and he appealed to have the fee returned, especially as a recent official decree abolishes the payment of fees on the conferring of such titles, but the highest authorities have finally definitely declined to return the fee. The case has been watched with great amusement in both medical and lay circles.

Admission to the Approaching International Medical Congress.—The Paris *Semaine Medicale* observes that one does not need to be much of a prophet to foresee that the approaching International Medical Congress at Madrid is already stillborn. It is not a medical congress but a congress of physicians, druggists, dentists, veterinarians, midwives, professors of all kinds and of all branches and journalists on the lay press. The offensive regulation in regard to acceptable members has been given in full in these columns as also the amendment sent out in the last communication from the committee of organization—pages 90 and 716. The *Semaine* continues: "What physician, scientist or conscientious practitioner, seeing the dignity of the profession thus assailed, will consent to take part in such a congress? What truly high-class medical journal will open its columns to the report of such a heterogeneous collection of communications from men foreign to the profession?"

X-Ray Burn Damage Case in Germany.—The *Allg. Med. Ct.-Ztg.* gives the details of the suit brought against "Dr. Sch." by a female patient whom he treated with the Roentgen rays to destroy a beard-like growth on the chin. A burn developed in consequence involving not only the chin but the neck and part of the chest. He was condemned to damages of $75 on account of the fact that he continued the treatment after the skin showed signs of irritation by its redness. He claimed that this redness was the proper reaction to the rays, and appealed to have a truly competent expert summoned to decide the question, as for instance, Schiff or Freund from Vienna. The ordinary experts who participated in the case gave conflicting testimony as usual in this new field. He also claimed that he was not responsible for the devastation caused by the burn as it was treated by other physicians who applied ichthyol, carbolic, etc., while experience has shown that strong measures are injurious in such cases and that these *x*-ray burns should be treated with exceptional mildness.

Correspondence.

Public Health and Schools.

St. Louis, Sept. 16, 1902.

To the Editor:—Given a crowded school and a limited number of drinking cups, and we have the conditions that are sufficient to increase the danger of diseases that can be communicated from child to child, a danger which is already great from the necessary crowding together of children in schoolrooms. On the principle that prophylaxis is greater than cure, the preventive measure consists in giving each child a tin cup and in teaching him to look on it as much his own as are his school books and his slate. The cost is trifling and the safeguard great. The communion service cup has already been made the subject of suspicion as a medium and vehicle of conveying contagion. How much greater, then, is the danger to children of a common drinking cup with their extremely sensitive and responsive predisposition to external morbific influences. The eyesight of children is important, but more important the means taken to prevent their contracting diseases which either kill them or maim them in health and usefulness for after-life.

Another point that seems to invite reform is in the matter of sufficient water-closet accommodation. Children are notoriously irregular in their habits and indifferent to the calls of nature and as a rule constipation is prevalent among them. To my mind this constipation arises as much from lack of opportunity when the need arises as from the other causes that bring about the condition. Often the foundation of a lifetime of drugging and pill-taking is laid during school life.

J. R. Clemens.

Queries and Minor Notes.

THE MEDICAL COLLEGE STATISTICS FOR 1902.

Hanover, N. H., Sept. 8, 1902.

To the Editor:—Our professor of pathology has called my attention to the fact that in the summary on p. 562 of The Journal of September 6, while our laboratory facilities for work in physics, biology, chemistry and physiology are mentioned, no mention is made of laboratory facilities for work in histology, pathology and bacteriology. Doubtless in putting out such a mass of statistics some omissions are unavoidable, but the reference to certain laboratories makes the failure to name the others significant. We value our work in the laboratories not named highly. Yours truly,

William T. Smith, Dean, Dartmouth Medical College.

Note.—Our statement concerning the laboratories was prepared, submitted to the college authorities, corrected by them, returned to us and printed exactly as corrected, as the original manuscript before us shows.

Cincinnati, Ohio, Sept. 5, 1902.

To the Editor:—I would like to call your attention to the fact that there are some mistakes in the items relating to the Miami Medical College given in your issue of September 6. In giving the fee for the first year the amount should be $105, instead of $115; that for the second and third years should be $100 each, and for the fourth year, $125. The Secretary of the college is Dr. W. E. Lewis, 409 East Fifth St., and the Dean is Dr. J. C. Oliver, 628 Elm St. Yours truly, J. C. Oliver, Dean.

Note.—After a re-examination of the college catalogue for 1902-3 we would give the total fees as $115, $105, $105 and $130, for the first, second, third and fourth years respectively. Dr. Oliver errs in not noting our language: "Total fees." This term is intended to cover all the fees, including the hospital and breakage fees which he disregards. Of these two, the former is payable annually and the latter is payable once. We erred in adding the latter to each year's fees, instead of to the first year alone.

Miscellany.

Teaspoons as dose measures continue in use in spite of the fact that they vary greatly in capacity. It is not necessary to collect souvenir spoons in order to find out the great discrepancy in the size of a spoon when compared to the regulation "one fluid dram" measure. Unfortunately, some of the dose glasses are as far from the mark as any teaspoon. If physicians and pharmacists will give the subject particular attention, they can soon educate the public up to the point of using only accurately graduated medicine glasses when taking liquid remedies.—*Meyer Bros.' Druggist.*

The Metric System a Necessity.—We have pointed out, says *Meyer Bros.' Druggist*, on various occasions that the metric system would be adopted by the United States Government just as soon as our commercial relations with the world at large reached that proportion which would make the adoption of the metric system a matter of necessity. It seems that our country has about reached that point. The committee on coinage, weights and measures has decided to report favorably the Shafroth bill providing for the adoption of the metric system by the government of the United States. A lengthy argument is made in favor of the metric system, but the following paragraph shows the burden of the plea for its adoption:

> As we have only just entered upon a commercial conquest of the world, the utility of the metric system will become more and more apparent and the necessity for its adoption more urgent with each year of our growing export trade. The extension of our governmental functions to the Philippines, Cuba, and Porto Rico, brings into the circle of our commercial operations millions of people to whom the metric system is the recognized standard and to whom our own cumbersome systems of weights and measures are a strange and unknown language of trade. It seems to your committee that every argument is in favor of the unification of standards of weights and measurements throughout the world, and for us to insist upon an adherence to our own antiquated standards is not in accord with the progressive nature of our people and the progressive tendency of this age.

Membership in the County Medical Society.—A county medical society is in no sense to be compared to a social club, although certain social features properly belong to it. In a club, membership is granted or denied for personal reasons, and rightly so. . . . Membership in county medical societies, carrying with it, as it does, membership in the state medical society and giving the privilege of joining the American Medical Association, should only be denied to those who are not legally qualified to practice and to those who can be proven guilty of unprofessional conduct. There will always be in every community, medical men who are personally, for this or that reason, objectionable to some of their fellow practitioners. This is, of course, the case with all other classes of men, but no lawyer, for instance, is denied admission to the bar association of his county for purely personal reasons. In small county societies, where the individual members are brought into very close relations with each other, individual likes and dislikes are, of course, more strongly in evidence than in larger communities and some friction is inevitable, but we feel that, since very many of the prejudices and quarrels among physicians are the result of misunderstandings, the best way to promote harmony and good feeling, is to meet together occasionally for discussion of medical subjects, and for social intercourse as well, and thus get to know each other better. In this way many men have been brought to understand and to like each other who had previously been kept apart for some trivial reason which perhaps originated in an entire misunderstanding and which was readily explained away. It is never wise to be unduly sensitive and it is worse than foolish to believe all that is reported by patients, nurses or meddlesome women about either one's self or one's fellows, and it is frequently such idle and vicious tattle that is responsible for hard feeling between doctors. We believe that frequently meeting together in county medical societies will do very much to dissipate misunderstandings and to promote general professional harmony.—*St. Paul Med. Jour.*

Clippings from Lay Exchanges.

A RAPID RESURRECTION.

Evansville, Ind., April 13.—"Last night, ——, 40 years old, was brought back to life by the injection into her arm of a half-pint of salt solution. The patient was taken to a local hospital for an operation, after which the physicians discovered that her heart had ceased to beat. . . . five doctors pronounced her dead. As a last resort a vein in the right arm was opened and the salt solution injected. In three seconds the patient arose on the operating table and asked for something to eat."—*Chicago Record-Herald*, April 14, 1902.

THE ASSOCIATION SETS.

"Dr. C—— left for Omaha Tuesday to attend the State Medical Association which sets the sixth, seventh and eighth. As president of one section he is billed for a paper on gyneacology and absteterics. The Dr. takes great pleasure in such gatherings."—*Albion* (Neb.) *Argus*, May 9, 1902.

ICELANDIC CANINOPATHY.

"J—— W——, a patient at the Holy Cross Hospital, died yesterday. . . . Dr.—— finally reached the conclusion that the patient's disease was echinococcus, peculiar to Iceland, and superinduced by association with dogs."—*Salt Lake* (Utah) *Tribune*, Nov. 9, 1901.

MISSIONARIES NEEDED IN NEWPORT.

"Dr. —— of ——, Ind., died at 12:05 a. m. last Sunday, May 11, 1902, in Terre Haute, from effects of a surgical operation for fistula in ano. About nine-tenths of the surgical operations of the present day result in death."—*Newport* (Ind.) *State*, May 14, 1902.

TUBERCOLOSIS AND CONSUMPTION.

"Dr. S—— of New York has come out with a lengthy article in which he states that tight lacing causes tubercolosis and consumption. He says that with tight lacing women cannot get proper ventilation into their lungs."—*Northfield* (Minn.) *News.*

TEDIOUS DELIVERY.

"The feature of the evening was an address delivered by Dr. —— on 'Dieting Upon the So-called Dyspeptic Cases.' The address . . . engaged the rapt attention of all present during the one hour of its deliverance."—*Bel Air* (Md.) *Times,* July 20, 1901.

SUBDIVISION OF SPECIALTIES.

"Dr. —— left to-day. . . . to attend the annual meeting of the Phthalinogical and Laryngolagical Association."—*Joliet* (Ill.) *Republican,* June 15, 1902.

DID HE TAKE IT STRAIGHT?

"Dr. V—— B—— sold his shop, medicines and practice to W—— D—— and then went to Chicago to take lectures on something else."—*Barry* (Ill.) *Adage,* May 8, 1902.

HE CLINICS FOR THE ALUMNI.

"Dr. R—— is attending the clinics of the Chicago College of Dental Surgery to-day, where he clinics for the Alumni of the College. Dr. R—— is Professor of Anaesthetics in the college."—*Waukegan* (Ill.) *Gazette,* Jan. 21, 1902.

(To be continued.)

Married.

Edmund K. Perkine, M.D., to Mrs. Ida B. Prentice, both of Philadelphia, August 29.

John W. Trask, M.D., to Miss Fleta Lawrence, both of Detroit, Mich., August 23.

Walter L. Ellis, M.D., Princeton, Ind., to Miss Forum of Whitehall, Ill., August 31.

Frank R. Steelsmith, M.D., to Miss Bertha B. Tice, both of Des Moines, Iowa, September 3.

Walter S. Bebb, M.D., La Grange, Ill., to Miss Edith Wyllie of Chicago, September 10.

James Ryan Garner, M.D., to Miss Birdie Duvall Patterson, both of Atlanta, Ga., September 3.

John D. Overholzer, M.D., Milledgeville, Ill., to Miss Lizzie Garwick of Coleta, Ill., August 28.

Elmer W. Sargent, M.D., Concord, N. H., to Miss Martha E. Rolfe of Penacook, N. H., September 3.

William Preston Delapierre, M.D., Hoschton, Ga., to Miss Ruby Camp of Atlanta, Ga., September 3.

William Myron Weaver, M.D., Hartford, Conn., to Miss Julia Frances Bartlett of New York City, August 25.

Gould Shelton Higgins, M.D., Wethersfield, Conn., to Miss Marie Cunningham Bacon of Scotland, Conn., September 3.

Deaths and Obituaries.

William B. Wynne, M.D. University of Vermont, Burlington, 1857, who served through the Civil war as assistant surgeon of the Fifty-third Pennsylvania Infantry, was then transferred to the First Division, Second Corps, Army of the Potomac, promoted to surgeon of the Fourteenth Pennsylvania Infantry, and then made surgeon-in-chief of the Middle Military Division, and on the staff of General Custer, and who, after his discharge in 1865, practiced in the oil regions of Pennsylvania, and for the last 18 years in Phenixville, died at the Phenixville Hospital, August 16, after an illness of a year, aged 70.

Clayton M. Daniels, M.D. University of Buffalo, 1880, one of the most prominent physicians of Buffalo, for 17 years surgeon of the Sisters' and Emergency hospitals, for four years professor of anatomy at the Niagara University, and attending surgeon for several railways, died at his home, September 6, from blood poisoning after an illness of nine months, aged 48. He was one of the founders and an ardent advocate of the Emergency Hospital, of which he was chief surgeon at the time of his death.

Monroe T. Pultz, M.D. College of Physicians and Surgeons, New York, 1868, a prominent physician of Dutchess County, N. Y.; vice-president of the Dutchess County and Medical Association and a member of the New York State Medical Association and the American Medical Association, committed suicide at his home in Stanfordville by shooting himself through the head, while despondent over the death of his wife; he was 59 years old.

Claudius B. Webster, M.D. College of Physicians and Surgeons, New York, 1844, the oldest alumnus of Dartmouth College, United States Consul at Sheffield, Eng., for the longest consecutive term on record—sixteen years—and a surgeon during the Civil war, died at the residence of his nephew in Concord, N. H., September 8, aged 86.

Joseph Garland, M.D. Medical School of Maine, Brunswick, 1844; Jefferson Medical College, 1847, the oldest physician on Cape Ann, for more than half a century a practitioner of Gloucester, Mass., and some-time mayor of that city, died at his residence, September 4, from paralysis after an illness of three weeks, aged 80.

Reuben M. Sutphen, M.D. New York University, 1847, a practitioner of Newark, N. J., for more than 35 years, and a member of the Newark Medical Association, the Essex District Medical Society and the Medical Society of New Jersey, died at the home of his son, in Old Short Hills, N. J., September 2, aged 83.

William O. Xander, M.D. University of Pennsylvania, Philadelphia, 1895, a promising young physician of Philadelphia, was thrown from his carriage, accidentally, September 5, sustained a fracture of the skull and died at the Methodist Hospital, September 7, aged 35.

Henry P. Shattuck, M.D. Harvard University Medical School, Boston, 1866, who served as an assistant surgeon in the Civil war and was a member of the Massachusetts House of Representatives in 1873-1874, died at his home in Brooklyn, N. Y., September 6, aged 58.

Michael Bradley, M.D., U. S. Navy, retired, an assistant surgeon in the navy in the Civil war, in 1879 commissioned a medical inspector, and from 1888 to 1895 medical director of League Island Navy Yard, died at his home in Philadelphia, August 27, aged 65.

Ignatius G. Drury, M.D. University of Louisville (Ky.) 1862, was found dead in bed, from heart disease, at his home in Knottsville, Ky., September 4, aged 75. He was a member of the State, District, and Daviess County medical societies.

Christian C. Baumgartner, M.D., who graduated in medicine in 1861, but forsook that field for the pulpit after fourteen years and then returned to practice, died at his home in Elkhart, Ind., from heart disease, September 4, aged 60.

William R. Taylor, M.D. Medical College of Ohio, Cincinnati, 1889, a physician of Clark's Hill, Ind., died at St. Elizabeth's Hospital, Lafayette, Ind., from typhoid fever, August 26, after an illness of four weeks, aged 57.

George T. Scarburgh, M.D. Jefferson Medical College, Philadelphia, 1858, an old physician of Accomac Courthouse, Eastern Shore, Va., died September 3, aged 66. He was an assistant surgeon in the Confederate service.

Julia M. Patten, M.D. Northwestern University Woman's Medical School, 1880, who had practiced for fifteen years at Holyoke, Mass., died suddenly September 8, from heart disease while driving near Somers, Conn., aged 43.

George S. Graham, M.D. Jefferson Medical College, Philadelphia, formerly a practitioner of Florence, Pa., and in 1885 and 1886 a member of the state legislature, died at his home in Burgettstown, September 10, aged 62.

Azel Backus, M.D. University of Pennsylvania, Philadelphia, the oldest physician in Rochester, N. Y., who during the Civil war was provost-marshal's surgeon for the Army, died at his home, September 2, aged 75.

William J. Wentz, M.D. Jefferson Medical College, Philadelphia, 1865, died at his home in New Providence, Pa., September 5, from kidney disease, aged 64. He was a member of the American Medical Association.

Josiah G. Graves, M.D. College of Physicians and Surgeons, New York, 1857, an old practitioner of Nashua, N. H., died at his summer home, Marblehead Neck, Mass., after a long illness, August 28, aged 70.

Hollie P. Robertson, M.D. Toledo (Ohio) Medical College, 1900, accidentally shot himself while superintending the construction of his new residence at Almond, N. C., and died September 6, aged 24.

Isaac W. Church, M.D. University of Wooster, Cleveland, Ohio, 1871, *formerly* a practitioner of Locke Town and Nappanee, Ind., died at the home of his sister in Middlebury, Ind., August 25, aged 61.

John J. Schlawig, Jr., M.D. College of Physicians and Surgeons, Chicago, 1891, died at his office in Sioux City, September 8, from the effects of an overdose of chloroform, aged 35.

John B. Kearney, M.D. Bellevue Hospital Medical College, New York, 1881, died suddenly from heart disease, at his home in Oregon, Mo., September 5, aged 46.

Nelson Price, M.D., St. John, N. B., who went to South Africa with the hospital corps of the Canadian Mounted Rifles, has died from enteric fever, aged 28.

Eugene E. Storck, M.D. University of Buffalo, 1878, died at his home in Buffalo, from consumption, September 10, after an illness of seven months, aged 47.

William Lapsley, M.D. Toronto (Ont.) School of Medicine, a well-known Canadian physician, died at Wesley Hospital, Chicago, September 4, aged 69.

Caswell T. Poe, M.D. Cincinnati University, 1849, died at his home in Grand Island, Neb., September 8, after an illness of eight days, aged 72.

Robert B. Benham, M.D. Jefferson Medical College, Philadelphia, 1876, died suddenly from heart disease in Mabton, Wash., September 2.

James G. De LaFonte, M.D. Queen's College, London, Eng., 1856, died at his home in Springfield, Mo., September 5, from paralysis, aged 70.

John H. Gardiner, M.D. Rush Medical College, Chicago, 1872, died at his home in Mahomet, Ill., August 29, from paralysis.

James G. Allen, M.D. Arkansas University, Little Rock, 1891, died at his home in Bratford, Ark., September 2, aged 80.

Thomas Hickey, M.D. Jefferson Medical College, Philadelphia, 1894, died at Shamokin, Pa., August 6, from tuberculosis.

John C. McKinnon, M.D. Harvard University, Boston, 1870, died recently at his home in Antigonish, N. S., aged 54.

George Waters, M.D. Toronto (Ont.) University, 1868, died at his home in Coburg, Ont., August 3, aged 65.

John H. Harris, M.D. Bellevue Hospital Medical College, 1866, died at his home in Yarmouth, N. S., June 15.

Calvin T. Dripps, M.D. Rush Medical College, Chicago, 1880, died at his home in Staunton, Ill., August 27.

State Boards of Registration.

Texas Announcement.—The next regular examination by the Texas Board of Examiners will be in Dallas, October 7 to 10. Further information may be had of the secretary, Dr. M. M. Smith, Austin.

Virginia Examination.—Dr. R. S. Martin of Stuart, secretary of the Medical Examining Board of Virginia, reports the examination held at Richmond, June 16-19, as follows: Number of subjects, 9; total questions, 69, of which 60 were to be answered; percentage required to pass, 75; examination partly oral and partly written; number examined, 170; passed, 63; failed, 18; partial examination, 89:

Association News.

Saratoga Meeting of the Secretaries of State Medical Societies.

In response to a call issued by Dr. Geo. H. Simmons, Secretary of the American Medical Association, the secretaries of the various state societies met in the United States Hotel, Saratoga Springs, N. Y., June 10, 1902. The meeting was called to order by Dr. Geo. H. Simmons. Dr. H. A. West of Texas was elected chairman and Dr. J. L. Stewart of South Dakota was elected secretary. Dr. Foshay of Ohio made a few remarks on the object of the meeting. Dr. West spoke of the importance of the meeting and the advantages which secretaries could obtain by interchange of ideas.

Dr. J. N. McCormack, of the Committee on Organization, was invited to attend and address the meeting. He spoke of having an organization of state presidents and also a permanent organization of state secretaries. He spoke of having a national organizer who should visit state society meetings, and also visit physicians personally or call meetings by counties and induce them to come into state and national societies.

Dr. Geo. H. Gorham of Vermont spoke of organization in his state and favored a national organizer. Dr. Stewart favored a national organizer and thought one could do a great deal of good in South Dakota. Dr. Monte Griffith said that the District of Columbia was well organized and did not need the help of an organizer. Dr. Runyon of Arkansas spoke in favor of a national organizer and thought that such a man, with the aid of the new plan of organization of the American Medical Association, would bring all good men into line. Dr. McCormack thought that Pennsylvania was all right, but Dr. Stevens said that there was room for improvement and that an organizer could do good there as well as in other states.

Dr. McCormack spoke of personal work among physicians. He said that the physician should be the model man of his community and above all petty quarrels. That he should also be the cleanest man personally, morally and socially in the entire community. He said that if we want people to look up to us we must be the kind of men that they can look up to.

The meeting adjourned to meet at 8:45 a. m., Wednesday, June 11, 1902.

JUNE 11, 1902, 9:30 A. M.

The meeting was called to order, with Dr. West in the Chair. Dr. Murrey, of Key West, Fla., was admitted, as he represented the secretary from his state.

The following resolutions were passed:

Resolved, That, after careful consideration, we endorse the plan of organization recommended by the Committee on Organization of the American Medical Association, and that we strongly advise all the states that have not already adopted said plan to take measures to do so at their next regular meeting, with such modifications as circumstances may require.

Resolved, That the secretaries of the state medical societies in convention assembled do hereby express our high appreciation of the address of Dr. J. N. McCormack of Kentucky, which demonstrated to us the great benefits of a more perfect organization and the possibility of perfecting the same in every state in the Union, and that we pledge ourselves to use our best efforts to promote organization in every way within our power.

The meeting adjourned to meet at the next annual meeting of the American Medical Association, time and place to be selected by the secretary of the American Medical Association.

J. L. Stewart, Secretary.

Societies.

COMING MEETINGS.

Medical Society of Virginia, Newport News, Sept. 23-25, 1902.

American Academy of Railway Surgeons, Kansas City, Mo., Oct. 2-3, 1902.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Birmingham, Ala., Oct. 7-9, 1902.

Medical Association of District of Columbia, Washington, Oct. 7, 1902.

Idaho State Medical Society, Moscow, Oct. 9-10, 1902.

Vermont State Medical Society, Burlington, Oct. 9-10, 1902.

Mississippi Valley Medical Association, Kansas City, Mo., Oct. 15, 1902.

Military Tract Medical Society.—The annual meeting of this society will be held in Monmouth, Ill., October 16 and 17.

American Electro-Therapeutic Association.—This association, at its twelfth annual convention held at Kaaterskill, N. Y., September 4, elected Dr. Daniel R. Brower of Chicago president.

Louisville (Ky.) Society of Medicine.—The annual election of this society was held September 2, with the following result: President, Dr. William H. Coleman; vice-president, Dr. Sidney J. Meyers, and treasurer, Dr. H. Davidson.

Wayne County (Mich.) Medical Society.—The first meeting of this society since the amalgamation was held September 4 at the Hotel Normandie, Detroit. Dr. Emil Amberg read a paper on "Surgical Anatomy of the Middle Ear as a Factor for Early Interference in Tympanomastoiditis."

Henry County (Ky.) Medical Society.—This society held its annual meeting at New Castle, August 28. Dr. W. T. Coblin, Campbellsburg, was elected president; Dr. Pink H. Crutchfield, Bethlehem, vice-president; Dr. John C. Cassity, Eminence, treasurer, and Dr. Albert P. Dowden, Eminence, secretary.

Wexford County (Mich.) Medical Association.—The physicians of Wexford County met at Cadillac, September 4, and organized a county medical association, with the following officers: President, Dr. Bartlett H. McMullen, Cadillac; vice-president, Dr. Walter B. Wallace, Manton, and secretary-treasurer, Dr. G. DeVere Miller, Cadillac.

Richland County (Ohio) Medical Society.—A meeting of the physicians of Richland County was held at Mansfield, September 5, to organize a county society. The constitution and by-laws as drafted by the American Medical Association were adopted. Dr. Josiah S. Hedges was elected president; Dr. William E. Loughbridge, vice-president; Dr. John M. Burns, secretary, and Dr. Maxwell J. Davis, treasurer, all of Mansfield.

Boulder County (Colo.) Medical Society.—At a regular meeting of this society, held September 4, the constitution and by-laws made to conform to the requirements of the American Medical Association were adopted. The reorganization plan from county to national body is heartily approved by the society. The following officers were elected: President, Dr. Emley B. Queal, Boulder; vice-president, Dr. Edward B. Trovillion, Gold Hill; secretary, Dr. William J. Baird, Boulder, and treasurer, Dr. W. W. Reed, Boulder.

German Congress of Anthropology.—The thirty-third session of the Congress was held at Dortmund August 5, with 250 members in attendance, but for the first time without Virchow, the founder of the Anthropological Society. Ranke of Munich reviewed the work of Marchand on the weight of the human brain, as the most important recent research in the line of anthropology. It is based on weights of 1834 brains, and

Thiol is a basic di-thio-salicylate of bismuth; a hydrocarbon obtained in a similar manner to ichthyol. It may be applied to ulcers and burns in the form of an ointment as follows:

℞.	Thiol		
	Vaselini albi, āā	ʒi	4
	Lanolini	℥i	30

M. Ft. unguentum. Sig.: Apply locally once daily. And as a dusting powder it may be combined as follows:

℞.	Thiol	ʒii	8
	Zinci oxidi	ʒiii	12
	Amyli	℥i	30
	Pulv. talci	℥ii	60

M. Sig.: Apply locally as a dusting powder once a day and cover with absorbent cotton.

Lead carbonate is frequently used as a coating for burns or ulcers. It may be applied in the form of an ointment or mixed with olive oil or linseed oil. Care should be observed in applying this preparation to a large surface, otherwise lead poisoning may be produced by absorption. The following combination is sometimes used:

℞.	Plumbi carb.	ʒi	4
	Pulv. amyli	ʒi	4
	Ung. aq. rosæ	℥i	30
	Olei olivæ	ʒii	8

M. Sig.: Apply locally to the affected part.

Potassium permanganate is of great value in the treatment of chronic ulcers employed as follows:

℞.	Pot. permanganatis	gr. xx-lx	1.30-4
	Aq. destil.	Oi	480

M. Sig.: To be used as a wash.

It may be used in the same manner in a saturated solution, first swabbing out the slough and flooding the ulcer for ten minutes. In this strength severe pain is produced for a few minutes. The ulcer should then be dried and packed with gauze soaked in the fluid. A heavy piece of gauze soaked in the same solution may be applied over the ulcer, covered with oil silk and the bandage applied. This dressing should be changed every day.

Acetanilid may be used to an advantage in the treatment of obstinate and irritable ulcers. It may be applied in the form of an ointment as follows:

℞.	Acetanilidi	gr. xx	1|30
	Vaselini albi	℥i	30

M. Sig.: To be applied locally.

Aristol has been frequently used as a dressing. It contains about 40 per cent. of iodin and is made by adding a solution of iodin in potassium iodid to an aqueous solution of sodium hydrate containing thymol, when aristol is thrown down as a reddish-brown precipitate. According to Shoemaker aristol is remarkably efficacious in promoting rapid cicatrization. Varicose ulcers of the leg, which are of such common occurrence in old people, heal very rapidly under the application of the following:

℞.	Aristol	gr. xv-ʒss	1-2
	Vaselini	℥i	30

M. Sig.: To be applied locally.

It has also been recommended in the treatment of fissured nipples applied in the form of an ointment in strength of 15 to 20 per cent.

As an application on erethistic ulcers where a great deal of pain accompanies the ulcer orthoform is of great service as a local anodyne in combination as follows:

℞.	Orthoformi	ʒiss	6
	Ichthyol	ʒiiss	10
	Vaselini	℥ii	60

M. Sig.: Apply locally.

Unna's paste is probably one of the most efficient dressings in the treatment of eczematous and varicose ulcers of the legs. The formula is as follows:

℞.	Zinci oxidi	ʒii	60
	Glycerini	℥v	150
	Gelatin	℥ii	60
	Aquæ	℥v	150

M. Ft. unguentum. Sig.: Paint well over the ulcer and apply a thin layer of gauze over which a second layer of the ointment is painted and a bandage applied.

The foregoing paste should be properly made by dissolving the gelatin in the water gently heated. The zinc oxid should be rubbed up with the glycerin and the gelatin solution added by stirring.

The following powder is of service when a dry dressing is indicated:

℞.	Iodol	ʒv	20
	Bismuthi subiodidi	ʒi	4

M. Sig.: To be dusted on the ulcer once daily and dressed with absorbent cotton.

The following combination containing gelatin and ichthyol may be used similarly to Unna's dressing:

℞.	Ichthyol	ʒiss	6
	Gelatin	ʒiii	12
	Zinci oxidi	ʒi	4
	Glycerini	ʒiii	12
	Aq. destil.	ʒvi	24

M. Dissolve the gelatin in the water gently warmed and add the ichthyol and zinc oxid, which have been previously mixed with the glycerin. Sig.: Thoroughly cleanse the ulcer and paint it over with this solution previously warmed.

Medicolegal.

SOME LEGISLATION OF THE YEAR 1902.

Iowa—May Employ Own Physician During Quarantine.—Chapter 105 of the Laws of Iowa of 1902, superseding Section 2570 of the Code, and relating to quarantine and the expenses thereof, provides, among other things, that nothing therein contained shall be construed to prevent any person quarantined, as therein provided, from employing at his own expense the physician or nurse of his choice, and no part of the expense of the physician or nurse employed by the Board of Health shall be apportioned to him under the provisions of this Act.

Iowa—Itinerant Physician.—Chapter 109 of the Laws of Iowa of 1902 amends Section 2581 of the Code by inserting the words "by himself, agent or employe," making the same read: Every physician practicing medicine, surgery or obstetrics, or professing to treat, cure or heal diseases, ailments or injuries by any medicine, appliance or method, who "by himself, agent or employe" goes from place to place, or from house to house, or by circulars, letters or advertisements solicits persons to meet him for professional treatment at places other than his office at the place of his residence, shall be considered an itinerant physician, etc., which requires a special license.

Iowa—Location of Pest-Houses.—Chapter 108 of the Laws of Iowa of 1902, relative to the erection and maintenance of pest-houses and hospitals, provides that when a controversy arises between municipalities or between boards of health thereof, respecting the location of pest-houses or hospitals for the treatment of infectious or contagious diseases, such matter shall be referred to the president of the State Board of Health, who shall forthwith appoint a committee of three members thereof, which committee shall upon two days' notice to the parties interested, investigate the matter and make such order in the premises as the facts warrant, and such order shall be final. The health officers of the municipality which is allowed to maintain a pest-house or hospital for patients affected by infectious or contagious diseases outside the limits of said municipality, shall have exclusive jurisdiction and control of such pest-house or hospital for the enforcement of all sanitary and health regulations.

Iowa—Sale of Cocain.—Chapter 110 of the Laws of Iowa of 1902 provides, under penalty, that no one, by himself, clerk, employe or agent, shall either directly or indirectly, sell or give away any cocain, or preparation containing cocain, except on the written prescription of a registered physician for medical purposes. And no such prescription shall be refilled except on the written order of a physician. However, nothing in this Act shall be construed to prevent the sale thereof to a wholesale or retail dealer in drugs nor registered physician, or licensed dentist for use in the practice of his profession. Peace officers shall see that the provisions of this Act are faithfully executed within their respective jurisdictions, and when they are informed, or have reason to believe that this Act has been violated, and the proof thereof can be had, they shall file information to that effect against the offending party before a magistrate, who thereupon shall proceed according to law. The county attorney shall prosecute violators of this Act.

Iowa—Enforcement of Rules of State Board of Health.—Section 2572 of the Iowa Code providing that local boards of health shall obey and enforce the rules and regulations of the state board, and peace and police officers within their respective jurisdictions, when called on to do so by local boards, shall execute the orders of such board, is amended, by Chapter 107 of the Laws of Iowa of 1902, by adding thereto the following: If any local board of health shall refuse or neglect to enforce the rules and regulations of the State Board of Health, the State Board of Health may enforce its rules and regulations within the territorial jurisdiction of such local board, and for that purpose shall have and may exercise all of the powers given by statute to local boards of health; and the peace and police officers of the state, when called on by the State Board of Health to enforce its rules and regulations, shall execute the orders of such board. All expenses incurred by the State Board of Health in determining whether its rules and regulations are enforced by a local board of health, and in enforcing the same when a local board has refused or neglected to do so, shall be paid in the same manner as is now provided for the payment of the expenses of enforcing such rules and regulations by local boards of health.

Maryland—Tuberculosis Commission.—Chapter 451 of the Laws of Maryland of 1902 authorizes the governor of the state to appoint a commission, to be known as the "Tuberculosis Commission," to consist of five persons, three of whom shall be physicians, whose duty it shall be to investigate the prevalence, distribution and causes of human tuberculosis in the state, and to determine its relations to the public health and welfare, and to devise ways and means for restricting and controlling said disease. The members of the commission shall serve without pay, except expenses actually incurred, and shall continue in office for a term of two years from the date of their appointment. They shall report the results of their investigations not later than Jan. 1, 1904. All hospitals, dispensaries and other institutions having medical officers, and supported in whole or in part by public funds of the state of Maryland, or of any city or county in the state, shall cause to be made on blanks furnished by the tuberculosis commission, records of such facts as may be available, for the use and purposes of said commission, concerning every case of tuberculosis coming under the care of such institution. The records so obtained shall be and remain the property of the institution where they are made; provided only, that the tuberculosis commission shall have free access to and use of such records during the period for which this Act shall remain operative.

1. **Organacidia Gastrica.**—This is, according to Knapp, the most frequent and important disease of the stomach. He recognizes three forms, organacidia gastrica simplex, gastrosia fungosa and zymosis gastrica. The first of these is due to the presence of organic acids caused by the ingestion of too much acid foods such as pickles, etc., and is relieved by an emetic or cathartic. The most frequent disease of the three is gastrosia fungosa, due to the presence of mold in the stomach. Knapp describes the presence of this by the appearances under the microscope, and remarks on the comparatively slight mention in literature. It is introduced through the diet. Just how the molds lodge there does not seem to be so definitely decided. He thinks that the fungus growth is very much influenced by saccharin matter in the chyme. The symptoms are various, according to the quantity and the degree of concentration of the organic acids. In the milder cases the symptoms may be interpreted by the patient as hunger, or increased desire to eat. The symptoms may vary from simple uneasiness to severe pain and cramps, and every gradation between these. The pains either appear before or after meals, and when they assume the character of cramps they come after eating, and at various hours according to the special conditions in the case. The presence or absence of HCl has its influence; the earlier this is secreted and the larger quantity, the later will the pains appear. The summary of the symptoms are: Heartburn, rawness or pain, spasms or cramps, in the region of the

pylorus and posteriorly on the left side at about the ninth dorsal vertebra, burning sensation in the epigastrium, rawness and burning behind and along the sternum and between the shoulder blades, a choking sensation, dryness in the throat, thirst, polyuria, excessive perspiration, sour taste, regurgitation of sour masses, vomiting, and, as a rule, headache, which is most often of the frontal type. The clinical symptoms must be confirmed by an examination of Ewald's test meal, and the quantity and quality of chyme. This is of a green color due to mold, and has a sweet odor caused by succinic acid. The prognosis is good in uncomplicated cases. In complicated cases it will depend upon the nature and extent of the complication. If long continued it may have for its sequel inflammation of the pyloric region and insufficiency. Varicose veins may thus cause rupture, and the dietetic treatment is avoidance of anything that may carry mold into the stomach, and having food freshly cooked. Knapp usually gives HCl at meals, and a mixture of equal parts of sulphuric and phosphoric acids 10 to 20 minutes after meals, according to the existing conditions. Fifteen drops of this acid mixture in a glassful of water, preferably warm. The dilute nitric acid is also good, but needs watching. Some cases seem to need arsenic as a later treatment. Zymosis gastrica is due to the presence of yeast cells and is caused by ingestion of food containing yeast. The microscopic test is the presence of yeast cell chains, and the chemical test will be for acetic and butyric acids. The prognosis in recent cases is even better than in the former condition, but complications are more serious. The treatment is mainly the same as that in the disease already mentioned. The diet must be more guarded. Stale bread must be prohibited, fruits that contain yeast, soda water, cabbages, turnips, radishes, raw onions, beans, unless stripped of their outer coverings, peas only when split, and acid foods. Coffee and tea must also be excluded. Only a moderate amount of milk should be allowed. The mechanical treatment is the same as that in the former disease—gastric lavage. The complications mentioned are ulcerations, and in children laryngismus and pharyngeal inflammations. The influence on the intestines can not be favorable. The esophagus may also suffer.

3. **The Health of School Girls.**—Newton thinks that girls suffer greater handicaps in school life than boys, and are more apt to work beyond their strength and suffer from effects of school strain. He thinks we should begin the physical education of women earlier and make it more thorough, and dress them differently if they wish to have an equal chance with men as workers.

4. **Prostatic Gonococcal Auto-Reinfections of the Urethra.**—The summary of Townsend is given as follows: "1. Early and vigorous efforts should be made to prevent gonorrheal prostatitis. 2. Once established, all care should be taken to prevent it from becoming follicular and chronic. 3. Auto-reinfections of the urethra from chronic prostatitis can be differentiated from acute infections. 4. An opinion on the probabilities of future recrudescences should be very guarded. 5. Each prostatic massage should be immediately followed by thorough irrigation of both portions of the urethra, to prevent recurrent acute urethritis. 6. Omission of this irrigation is sometimes permissible for diagnostic purposes."

6. **Vaginal Suturing of the Round Ligaments.**—Vineberg reports later results of his formerly reported cases, and also those of several later ones. He thinks that his method of operating is a proved success, but emphasizes the great care required not to wound the anterior wall of the uterus in bringing it into the vaginal incision. He criticises the very roundabout methods adopted by some operators for the relief of retroversion for the sake of being original. He asks why they try to perform all kinds of fantastic tricks with the round ligaments, when the simplest and most reasonable thing to do is to suture them to the vaginal wall.

7. **Porto Rico.**—Coley speaks of Porto Rico as a health resort and gives advice as to its climate. The presence of tuberculosis among the natives does not contraindicate its being a health resort, for the natives have been living under most unsanitary conditions. The single feature of the excessive humidity must be considered by tourists, and there is vast room for improvement in accommodations. Visitors in Porto Rico, as in all other tropical climates, must pay strict observation to the simple rules of hygiene and diet.

8. **Tubercular Cystitis.**—Bissell describes the symptoms of tubercular cystitis, and calls attention particularly to the signs of pain, tenesmus, frequency of urination and hemorrhage. Later, pus and ulcerated tissue may appear in the discharge. He thinks the frequent voidance of clear urine without pain and without apparent cause, with a few drops of bright red blood at the end, or less frequently at the beginning, is almost a sure sign of beginning tubercular cystitis. We should look into the history of the patient, making a thorough examination in every respect. The following is a good rule in routine practice: "Given a patient with slight infiltration of the apex of one lung, or a suspicious epididymitis, a renal tuberculosis, a tubercular peritonitis or a lymphatic infiltration, even without the finding of the bacillus or any other sign of consumption, who develops vesical symptoms, it is better to consider it a case of tubercular cystitis than to remain in doubt until the contrary is proven." The history of a trauma or injury, a previous attack of acute or chronic urethritis, overdistension of the bladder, instrumentation, irritant injection, may also help. The pulse is also noticed; it is usually more frequent. Albumin is also usually present to some degree. The greatest difficulty is in diagnosing this condition from stone, or more particularly, differentiating stone from tubercular cystitis. He advises against early operative treatment before trial of rest and elimination of the cause and building-up of the resistance of the system generally.

9. **Nephroptosis.**—Goelet thinks that temporary fixation of the kidney in a proper position for a short time after exciting the necessary degree of irritation to induce plastic inflammation, is usually sufficient to induce permanent fixation, therefore temporary sutures inserted so they will not cut out, and tied on the skin surface, are usually sufficient. His method is described by him as follows: "A vertical incision is made along the outer border of the erector spinæ from just below the last rib downward through the skin and fat down to the superficial layer of fascia; this is divided with scissors, the underlying muscles are separated in the direction of their fibers by means of blunt hooks and are held apart by broad retractors. The fatty capsule surrounding the kidney, which is exposed after dividing the deep layer of fascia, is drawn down and opened well up and well over toward the spine to avoid opening the peritoneum or wounding the intestine which bulges up into the wound. The kidney is then separated from its fatty investment all around and that part of the fatty capsule covering its posterior face is removed completely. It is important to separate the kidney completely from its attachment to the intestine upon its anterior face to obviate dragging upon it from that source. The redundancy of the fatty capsule on this side is also removed, taking care not to encroach upon the intestine or peritoneum. The suture material employed for the temporary sutures is silkworm gut rendered pliable by a method that I have described elsewhere. The needle used is very small, so as to cause as little injury as possible to the fibrous capsule. Two sutures are inserted, the upper one at about the center of the kidney and the other at about the junction of the middle and lower third. The lower suture is inserted first from above downward under the fibrous capsule only for a distance of about half an inch from its entrance to its exit; then it is inserted transversely about the same distance, and again from below upward at an obtuse angle to the transverse insertion. Thus this suture has three insertions under the fibrous capsule only. The upper suture is inserted from above downward and from below upward, leaving the suture exposed upon the surface transversely for a distance of three-quarters of an inch. The ends of these sutures are carried through the structures of the back and brought out on the surface at the upper angle of the wound just below the lower border of the last rib. They are tied across the line of incision over a fold of several layers of gauze, which obviates cutting of the skin by the sutures and loosening of the loop.

When these sutures are both tied, the upper pole of the kidney is drawn up into its original position under the ribs and its lower half is brought into intimate contact with the muscles exposed in the wound. The kidney, which before could be seen to move up and down with respiration, is now seen to be immovably fixed. A strip of gauze is packed under and about the lower pole of the kidney and the end is brought out at the lower angle of the wound for drainage. This furnishes additional support to the kidney, lessening the strain on the sutures while it remains, and excites plastic inflammation. Iodoform gauze (5 per cent.) is used, because it is somewhat more irritating than the plain gauze, but it is not wise to use a higher percentage of iodoform, because of the susceptibility of some patients. In one of my cases iodoform poisoning resulted from using 10 per cent. gauze freshly prepared with alcohol and ether. The gauze is removed always on the second or third day following the operation. In closing the wound, a continuous suture of plain catgut is used for approximating the superficial fascia, and interrupted adhesive strips upon the skin surface. The patient is kept in bed for three weeks. During the first week she is kept constantly upon her back, being turned upon the side only to renew the dressings. The sustaining sutures are not removed until the day before she gets up. Primary union is the rule, and the resulting scar is not disfiguring. It is advisable to have these patients wear a snugly-fitting elastic abdominal belt upon getting up and for several months after, as most of them have lax abdominal walls, which, if not supported, deprive the kidney of the normal support of the abdominal organs."

10. **Uremia.**—This condition, which Grandin prefers to call mixed toxemia, is considered here as a post-operative sequel or as a complication of pregnancy or the puerperal state. The prophylactic treatment, he says, consists in relieving strain on the emunctories and securing free action of the liver and the sweat-glands. He believes in an absolute milk diet associated with some form of readily assimilated iron, and advises regular Turkish baths when there is no heart complication, and a drug which favors the action of the liver, his preference being elaterium in small and repeated doses. Plenty of water should also be ingested. In acute cases all drugs which tend to whip the kidneys should be avoided. He would use the nitrites, and the best form, he thinks, is nitroglycerin hypodermically. He pushes this fearlessly, to the extent of 1/20 of a grain, repeated every 15 to 20 minutes. To promote liver action he uses elaterium in eighth-grain doses at intervals, and with these drugs he also used digitalis to tone up the left heart. High hot saline injections of gallons of hot water thrown in and allowed to come out are useful. This procedure should be kept up for hours if necessary. When toxemia is active, chloroform is one of the sheet anchors. For a bounding pulse he prefers bleeding to the use of veratrum. He is opposed to opium. The only condition requiring surgery is when the phenomena ensue as a complication of pregnancy, and the rapid evacuation of the uterus in addition to the other methods described, is then advisable. He would allow the woman to bleed some if the condition of the pulse suggests plethora.

13.—See JOURNAL of May 24, xxxviii, p. 1393.

14. **Pulmonary Valve Affections.**—Satterthwaite first notes the rarity of these lesions in adults, and reports six personal observations. He remarks that the more common congenital type is easily recognized by the cyanosis, clubbed fingers and toes and abnormal chest development, etc. In the acquired type the most important physical signs are: "1. Displacement of the apex. 2. Diastolic thrill in the second or third left space (in 20 per cent., Barie), from the edge of the sternum to a distance of one inch to the left of it, conducted down to the left edge of the sternum (Boyd). 3. Double murmur (in about 25 per cent.). 4. Diastolic bruit intensified by inspiration. 5. Implication of the lungs. 6. Murmur intensified in the sitting position. 7. When a long breath is taken the vesicular murmur is jerky. 8. Hemoptysis. 9. Dyspnea. 10. Usually, but not always, hypertrophy of the right ventricle. 11. Epigastric pulsation. The pulse has no distinctive character. Often there will be no bruit at all; we must, however, discriminate against aortic disease (insufficiency) by the absence of hypertrophy of the left ventricle by the Corrigan pulse. The murmur should be lower than an aortic." The diagnosis would be more frequent, he thinks, if physicians were more systematic in their examination. The prognosis is unfavorable in congenital cases, somewhat less so in acquired cases, as compensatory right hypertrophy may ensue, but is never very good. The patients usually succumb before middle age. Congenital pulmonary stenosis as a single lesion is excessively rare, but Satterthwaite reports a case and also one of apparent temporary stenosis from extra-cardiac pressure, relieved by evacuation of an abscess. He reviews the symptoms of these conditions more at length, also the apparent causes, imperfect development in the congenital form, and antecedent infections, especially rheumatism or specific disease in the acquired cases.

15. **Heart Disease.**—The points specially emphasized by Snively are: "1. Each patient showing a heart lesion must be a study unto himself. 2. No heart medicine is needed unless the myocardium is unable to do its work in a physiological way. 3. The heart muscle should demand more consideration than the heart murmur. 4. Rest is one of our best therapeutic agents. 5. We should try by every possible means to prevent myocarditis in all diseases where this condition is apt to rise. 6. After any severe disease process we should insist upon the patient resting in bed long enough to allow the myocardium to be restored. 7. We should improve the general nutrition of our patients and restore the blood to a normal standard by the use of blood tonics. 8. We should investigate the kidneys in all cases showing signs of cardiac incompetency. 9. Physical exercise, light gymnastics and properly selected diet are valuable aids in the treatment of cardiac disease."

17. **Tricuspid Diseases.**—The symptoms of tricuspid insufficiency are reviewed by Satterthwaite. They are seldom recognized during life, notwithstanding their prominence. The most significant one is a systolic murmur over the lower half of the sternum and ensiform cartilage, next epigastric pulsation, faintness of the second pulmonary sound, and of less importance, the jugular pulse. Simple fulness of the jugulars is also a noteworthy sign. The prognosis is generally bad. Tricuspid stenosis is also described and cases reported. It occurs chiefly in women and he says that given a woman under forty, with a diastolic murmur in the tricuspid area, where the pitch, quality or other characters distinguish it from the mitral murmur and with 1, a co-existing mitral stenosis; 2, an enlarged and dilated right auricle; 3, palpitation, cyanosis, dyspnea and edema; 4, the epigastric pulse, and 5, a previous history of rheumatism, it will be safe to make a diagnosis of tricuspid stenosis.

19. **Nasal Obstruction.**—This, especially when from septal deflection, is, according to Shields, a not uncommon cause of laryngitis; it causes acrid secretions which fall back and irritate the larynx. Mouth breathing may also play its part, especially when the obstruction is from hypertrophic rhinitis. Many cases of supposed laryngitis are, however, in his opinion, only reflexes from enlarged tonsils, and are improperly treated by local laryngeal applications when attention to the tonsils would suffice. The causes of septal deflections are also considered. He gives the greatest importance to trauma, and after this to adenoids, and race mixture. The operative procedures are described; for septal straightening he prefers Gleason's or Hajek's method. The crushing operations and splints are not considered favorably, as he thinks they do not insure against relapse.

21. **Pernicious Anemia.**—Billings finishes his article, which is a thorough discussion of the spinal and medullary changes in this condition, with the following conclusions: "1. That there is a well-established relation of diffuse cord degeneration with pernicious anemia. 2. It seems highly probable that the hemolysis and the cord changes are due to the same toxin. 3. While the source of the toxin is unknown, the fact that gastro-intestinal disturbance is so common in the disease would lead one to suppose that it is of intestinal origin. 4. The diffuse

degenerations of the spinal cord which occur in conditions without pernicious anemia do not appear to differ essentially from those of pernicious anemia. 5. It is possible that a common blood-circulating poison exists which may expend its force upon the blood in one individual, upon the nervous apparatus in another, and coincidently upon the blood and spinal cord in others."

27. **The Biologic Blood Test.**—Patek and Bennett review the history of this method of differentiation and report their own successful results in a murder case. Their method was essentially that of Uhlenhuth and they consider their results sufficiently positive, though they were not admitted in evidence on account of the delayed collection of the materials submitted to them.

29. **Typhoid Perforation.**—Seven cases, three of them successful, are reported by Hays. He calls attention to the distinction of the perforation symptoms from those of the following peritonitis, especially the local pain, collapse, etc., and thinks that ordinarily the diagnosis ought not to be difficult. The operation should be early to obtain a large percentage of recoveries.

32. **Crural Thrombosis.**—Schenck, from an analysis of the cases occurring in the gynecologic department of the Johns Hopkins Hospital, comes to the following conclusions: "Thrombosis of the crural veins is more common after pelvic operations than is generally recognized. It occurs more frequently in those cases in which large tumors, springing from the pelvic organs, have been removed. It rarely follows extrapelvic operations. In this series it has been infrequent after infected cases. The anemia and cachexia in consequence of new growths seem to be factors in its causation. Constipation and the use of enemata play a doubtful part in the etiology. Traumatism at the time of the operation should be borne in mind and deep retractors used with extreme care. Infection is undoubtedly of great importance, but its frequency is difficult to decide. This complication often occurs when least expected and usually late in convalescence. Albumin in the urine is more frequent in these cases than in those running an uninterrupted course. The pulse curve of Singer does not always occur. The results of rest and elevation for the full length of time are excellent. When the time is lessened, swelling and pain persist, and the danger of pulmonary embolus is increased."

34. **The Age of Consent.**—The laws of the different states as to this point are reviewed. Dyer holds that the age of consent should be raised to a point of years when some actual discretion may obtain. There are, he thinks, few females who fully appreciate their sex relation at eighteen, and the ages of consent in some states, Alabama and North Carolina for example, are ridiculously low.

35. **Electricity in Constipation.**—The utility of electricity for the relief of habitual constipation is discussed and cases reported by Cohn. He uses the static, sinusoidal, faradic and galvanic currents, with the former as his first choice. He sums up as follows: "Taking into consideration the fact that, of the twelve cases reported, 75 per cent. showed a complete cure, I have come to the following conclusions: 1. Electricity should not be employed as a last desperate chance after all other means have failed, but should be given a front rank in the treatment of this disease; 2, especially the static currents, with their powerful vibratory effects, should be employed more frequently than has been done heretofore; 3, the reduction of abdominal circumference by use of these currents is a proof of their tonic influence upon the abdominal muscles; 4, the most powerful means of obtaining this tonic condition is the administration of the swelling, or undulating current."

39-40. **Sigmoidopexy.**—The case reported by Jacoby was one of long standing and severe rectal prolapse, as shown by the illustrations. It was completely relieved by a McBurney incision of the left side, incision of the peritoneum and the sigmoid drawn until all the slack had been taken up and sutured to the abdominal wall with a kangaroo tendon suture carried under the anterior longitudinal band, then carried obliquely across, after which it was again passed under the band. Thus there existed two free ends opposite each other, which were carried through the *peritoneum*, *transversalis*, and internal oblique muscles on each side, respectively, giving an indirect figure eight when the two ends were tied. They were tied so that the opening was nearly closed and the bowel held firmly against the parietal peritoneum and abdominal wall. The remainder of the opening was closed with another kangaroo tendon, and the skin incision brought together with interrupted silkworm-gut sutures. The patient was kept on liquid nourishment for a little over a week and then put on a light diet, which was quickly changed to the full diet. He asked for discharge twenty days after operation. Jacoby thinks the figure eight suture that is employed is worthy of consideration because it brings into close and continuous contact the two serous surfaces, as well as the abdominal wall and intestine, and is better able to sustain the weight and tension.

43. **Intracranial Tension.**—Cushing's article is an elaborate report of experimental data and a discussion of the results. In conclusion he says: "From this rather superficial review of the alterations in the cerebral circulation as they are influenced by varying degrees of compression, some effects stand out with especial prominence. In the first place, the venous stasis, which becomes apparent on but a moderate increase of the tension, fortunately gives early evidence of itself in the eye-grounds except in those cases of local compression, in posterior basic meninges, for example, so remotely situated that the compression effects are not readily transmitted as far as the cavernous sinus and ophthalmic veins. Furthermore, local pathologic processes, such as are confined to the hemispheres, may be responsible for local circulatory disturbances sufficient to cause a cessation of function of a large part of the forebrain without leading in any way to a corresponding implication of the medulla. When, however, the local process is in the near proximity of, or, if remote, when its effects are so far reaching that the vital centers of the bulb are compromised, the one symptom which with regularity is called forth, and which betokens a serious alteration in the local circulation, is a persisting rise in blood-pressure, which may or may not be associated with a pronounced vagus pulse, with rhythmic alterations in blood-pressure and with a retardation of periodicities of the respiration approaching a Cheyne-Stokes type. The first and minor symptoms of compression are found in association with varying degrees of intracranial venous stasis, the major symptoms of 'Hirndruck,' with an approaching capillary anemia of the medulla."

44. **Thermic Fever.**—This article, based on 92 cases of thermic fever occurring in the experience of the writers at the Pennsylvania Hospital during the hot weather of July, 1901, includes only those showing a temperature of 100 F. and over on admission and not including the many cases of mere heat exhaustion. The conditions as regards convulsions, mental state, pupils, knee-jerk, urine, etc., are noted in a number of cases, though complete observations were not made in all. The previous habits of the patient seem to have an important bearing on the results. In the severe cases 50 per cent. of those where data were obtained gave an alcoholic history. The blood was examined in a certain number of cases both as regards the appearance and the blood count. They found an absence of high constant specific gravity and increase in the number of red cells which was rather surprising. The number of leucocytes varied. In some cases a leucocytosis chiefly in the polymorphonuclears was observed. They believe, however, that injection of large quantities of normal salt solution saves some patients. Treatment in the mild cases was simple; ice pack, aromatic spirits of ammonia and alcohol, and occasionally a cold bath. In the severer cases stimulants were used and an ice cap and the cold bath, or in obstinate or very severe forms the patients were rubbed with ice. Bleeding was not advised as a routine measure, but it was used in eight severe cases, of which several died. The use of normal saline solution was employed on theoretic grounds, and was found to be of value. Hypodermoclysis was employed in five cases, all severe, but it occupied too much time to be perfectly satisfactory. The injection into a vein was more applicable. The authors think

valuable results might follow the further study of diseases of the eye-ground, of the specific gravity of the blood, and its spectroscopic examination, frequent estimation of the leucocytes and more complete study of the toxicity of blood serum. They also believe that injection of normal salt solution in large quantities into the body has beneficial results, though they do not show exactly how it acts.

48. **Benign Cystic Epithelioma.**—Besides reporting cases Hartzell discusses others in the literature and remarks in conclusion that there is apparently more or less confusion as to the exact relationship of the different types. He thinks that these represent three affections, presenting lesions which can only be distinguished from one another with the aid of the microscope, but which are quite distinct in their nature and origin: "1, benign cystic epithelioma, in which the lesions are usually, but not always, situated upon the face, and have their origin in the basal layer of the epidermis and the external root-sheath of the hair; 2, cystadenoma, in which the eruption occurs upon the trunk, the tumors starting in the sweat-gland apparatus; and 3, hemangio-endothelioma likewise situated upon the trunk, but originating in a proliferation of the endothelium of the blood vessels."

49. **Post-Operative Non-Septic Leucocytosis.**—From a study of a number of operations with careful attention to the blood count, King draws the following conclusions: "1. An increase of from 5000 to 10,000 leucocytes per cubic millimeter following operation in from six to thirty-six or even forty-eight hours is a normal post-operative condition, provided it be not sustained. 2. Probably the maximum leucocytosis in the majority of cases occurs within the first twelve hours after operation, and is very transient. 3. The leucocytosis in the normal reparative process bears but slight relation to the pulse and temperature. 4. A post-operative leucocytosis of 10,000 or more above the individual normal, sustained for more than a few hours, may be looked upon with suspicion. 5. The apparent increase in number of erythrocytes following operation is not caused by an actual increase of red cells in the circulating blood."

50. **Entrance of Air into the Veins.**—The conclusions of Goodridge's experimental study are given as follows: "1. That entrance of air into the veins, even in small amounts, is to be dreaded, as it may result in death. 2. That death is due to gaseous distention of the right heart or to air emboli in the coronary vessels, and not to primary respiratory paralysis. 3. That combined treatment by aspiration and infusion we may expect to be attended with good results. In conclusion, I would say that I believe the statement 'that large quantities of air may be introduced into the veins without unfavorable result' to be pernicious teaching and not supported by fact." He remarks as regards the application of his experiments to the human subject that in operating in the region known as the danger zone, none but the prone position be permitted, for should one of the veins be injured the semi-prone or sitting posture predisposes to the entrance of air into the veins. If any dissection is necessary it should be performed with a blunt instrument, never with a scalpel. Special care should be used if the operation be for the removal of cancer or tuberculous glands which are more or less intimately connected with the adjacent structures. If warned by the hissing sound accompanying entrance of air into the vein, the finger should be pushed into the point to prevent further admission of air and the wound cavity should be filled with salt solution and the chest compressed forcibly. If bubbles are seen in the fluid contained they are due to air coming out. If, however, the heart become tumultuous and if the respirations become labored and the inspirations forced a needle should be inserted into the fourth left interspace one inch from the left border of the sternum. It should be directed upward and backward obliquely and the right ventricle will be entered; aspiration should be continued until the blood comes out unmixed with air. Then a normal salt solution at a temperature of 115 to 120 should be injected until an amount has been introduced equal to the quantity taken out. The most convenient point for this infusion is the median basilic vein.

53. **Treatment of Pneumonia.**—The present status of the treatment of pneumonia is summed up by Wilcox as follows: "1. Continuous, persistent, and generous administration of creosote carbonate. 2. Careful adjustment of mechanical conditions. 3. Thorough evacuation of toxins by all possible ways. 4. Temporary supplemental oxygen by inhalation. 5. Liquid diet until physical signs disappear. To be avoided are antipyretics, opiates, ill-advised external applications and slowly-acting heart remedies, as digitalis."

60. **Rectal Valves.**—Cooke reports here the opinions of a number of prominent surgeons with whom he has corresponded in regard to their views as to the existence of Houston's rectal valves, including among them Drs. Gant, Beach, Pennington, Howard A. Kelly, and Douglas, who all strongly hold to their existence and importance. He reports a case of operation and concludes that these structures are definite anatomical entities and should be recognized as such as much as the appendix vermiformis.

65. **Flat-Foot.**—Young discusses the diagnosis of flat-foot and the differentiation between rheumatism and other conditions which may suggest it, also its treatment. He recommends a method of measurement to indicate the condition in flat-foot, and gives the angular measure and also mentions the use of the inclined mirror in diagnosis. In the milder cases the restoration of the arch may be accomplished by the use of a pad of gauze held in place by adhesive plaster and by a bandage, or for permanent use a plate or steel spring covered with hard rubber. Exercise and massage also form an important part of the treatment, and should be done under the supervision of a physician. In the moderate degree of flat-foot, besides the measures already described, forcible correction under ether has been most satisfactory. If tenotomy of the tendo Achillis is required it should be performed. For forcible correction a pad should be held in position in the sole of the foot by plaster casts and worn several weeks, the treatment continued and ankle braces employed after its removal. In the severe forms operative measures should be employed, including procedures on the muscles and skin intended to shorten the arch of the foot by cicatricial contraction, and shortening or elongation of the tendons, as necessary. Only in exceptional cases will the removal of the astragalus be required.

66. **Pes Equinovarus.**—Davis relies on manual manipulations in preference to operation and thinks the latter will rarely be necessary if the first are thoroughly attended to. If the practitioner would begin this treatment in the earlier stages there would be far less old incorrigible conditions requiring operation.

67. **Talipes Equinovarus.**—Mann holds that no case of congenital flat-foot should be operated on until the child has learned to walk, which usually occurs from the twelfth to the twentieth month. With skilful manipulation and, if necessary, retentive apparatus, many cures can be effected when there is a slight deformity. Severe cases, however, require, besides the operation, mechanical treatment both previous and subsequent to it. The risk of operating in feeble children is to be considered, while mechanical treatment judiciously selected will never cause death. After the child can walk its body weight very materially contributes to the retention of the foot in the corrected position. Properly directed muscular action also aids in a cure. In operations done too early, except with the utmost care, relapses are liable to occur.

69. **Exophthalmic Goiter.**—Halstead holds to the hyperthyroidization theory of exophthalmic goiter and pleads that where a fair trial of the medical treatment has been made and the patient not too reduced surgical treatment is indicated. It is positively indicated where the goiter is large and causes marked pressure symptoms, especially where there is great dyspnea and asphyxiation is threatened. In very severe cases no prolonged operation can be done and only tracheotomy for temporary relief be borne. Another positive indication is where the degree of exophthalmus is such as to endanger their eye. Operations on the gland, however, frequently do not immediately influence the exophthalmus and sometimes do not aid at all. For such cases excision, preferably bilateral, of

the cervical sympathetic seems to be the best method of relief. The surgical treatment, as a rule, is more useful in cases of rapid development than in the chronic form. The operative measures are ligation of the thyroid arteries, exothyropexy, enucleation of nodular growths, and partial or unilateral excision. None of these excepting the latter is considered specially advisable by the author. The operations on the cervical sympathetic are simple section, partial resection, total bilateral resection and stretching. The latter can be left out of consideration. Partial resection gives on the whole more favorable statistics than simple section. Bilateral section seems to have given a fair amount of recoveries; according to Jaboulay, 58.9 per cent. recovered and 29.4 per cent. were greatly improved.

70. **Spinal Cord Degeneration.**—Pickett reports a case which seems to support the conclusion that we have in subacute degeneration of the cord two processes, one systematic, the other diffuse, and it is also a slight rebuttal of the view that the subacute combined degeneration of Russell, Batten and Collier is never associated with pernicious anemia.

73. **Drainage in Peritonitis.**—Pritchard protests against the use of drainage in diffuse peritonitis. He thinks we do not sufficiently rely on the peritoneum and that if we did some cases would be saved that otherwise die.

81. **Extra-Neural Disease.**—This designation is given by Hughes to diseases of the nervous system arising in other parts of the body, such as the nervous complications of diphtheria, malaria, syphilis, etc. He discusses the theories of Lugaro, Marinesco, Robertson and others in regard to the changes which occur in the neuron, chromatolysis, etc.

84. **Regicides.**—The article of Spitzka's is continued and is largely polemic, combating Talbot's views.

87. **Dipsomania.**—Kiernan reports a case of some forensic interest in which a dipsomaniac was convicted of murder on a second trial in which the case rather went by default. After his removal to the penitentiary his insanity developed so rapidly that in two months he was transferred to the criminal insane asylum and later pardoned, to be sent to an eastern insane asylum, where he now is, having delusions and other paranoiac symptoms.

88. **Locomotor Ataxia.**—Pope advises a generous diet, change of occupation, so as to avoid arm or leg strain, worry, care, etc., general hygienic measures, and for the drug treatment the only remedy he has found useful is nitrate of silver in 1/6 to 1/4 gr. doses three times daily one or two hours after meals. Iron, arsenic, quinin, cannabis indica, and glycerinated phosphates can be used for their tonic effects. Strychnia should be generally avoided. He has little faith in serum-therapy. Morphin may be used for the crises and other systemic treatment where indicated. Hydrotherapy is advised and the details given. He employs half baths, douches, etc. Electricity has been found useful in his hands, especially static electricity applied to the spine, extremities, etc., the sparks being as heavy as the patient can bear. Especial care should be given to the anesthetic regions, the soles of the feet, hips, etc. Lately he has been substituting high tension currents for the insulation and head shower and finds it has a marked influence in improving the general nutrition, removing the lightning pains and promoting a feeling of well-being. Next to the static current he thinks the galvanic, with the strength of 10 to 30 milliamperes, from the nape of the neck to the feet or labile to spine followed by a stronger current from a large pad over the lumbar region, or a current from the abdomen to the nape of the neck or lumbar region. He does not explain the *rationale* of the action of electricity and thinks it more or less empiric, but believes that it has decidedly good effects. He believes in massage and knows of no one agent that satisfies the patient as well as this, and in a few cases he has found suspension, though generally disused, still of value. Gymnastic exercises under proper supervision are of value, giving care, however, not to fatigue. He gives details as to these and says in conclusion that the disorder can not be treated by the general practitioner owing to the character of the apparatus, time, etc. No case should be considered hopeless, but every case will require close attention and individual study and the utmost patience and care on the part of both physician and patient.

90. **Epilepsy.**—Hansom believes that epilepsy can be prevented in many cases by proper care in childhood and puberty. Especial attention should be given to rickets, ascribed by Ohlmacher as the cause of epilepsy in many cases. The child that has inherited an unstable nervous system may contract epilepsy from an injury that a normal child would pass unscathed, and while traumatic causes may not always be prevented, much can be done to improve the resistance and to prevent the development of rickets and kindred disorders of assimilation in predisposed cases.

91. **Pneumonia of Infancy.**—Lapsley calls attention particularly to bronchial pneumonia of infancy, noticing the symptoms, physical signs, prognosis, etc. He protests against the use of the coal-tar antipyretics and would rely on sponging or warm baths, and aconite. He finds the latter drug useful in all forms of fever. The cough mixtures do not play much part in his treatment. Apomorphin and emetin will prove, he thinks, to be useful expectorants, especially adapted to the respiratory affections of childhood. Dry heat is best for local applications. Alcoholic stimulants are detrimental.

100. **Asphyxia in the Newborn.**—The most reliable sign of asphyxia before birth is in the fetal heart-tone, changes in frequency and quality. A steady slowing to 100 per minute, and certainly if below this, points to impending danger, and after this an increase to 160 or more, usually occurring after the diminution has been pronounced, implies death from vagus paralysis. If the quickening is primary it should have the same significance as slowing. Next in importance is the passage of fresh meconium with the liquid amnii. The discharge of meconium is analogous to the involuntary bowel movements that occur in other asphyxias, as drowning and strangling. Still another sign showing that asphyxia has already become serious, is feeling, seeing or hearing respiratory movements made by the child before complete birth. The prophylaxis is important. The waters should not be ruptured unnecessarily as the child is generally safe in an intact sac. Ergot should not be given during labor. No attempts should be made to hasten birth, especially in breech presentations. The fetal heart-tones should be carefully studied, especially toward the end of the second stage. The physician should be prepared to treat the accident. If the danger should be diagnosed *in utero* labor should be expedited as far as possible for the safety of the mother. If the child should die during its delivery leave the rest to nature, or, if operation is necessary, do embryotomy. After the child is born one must determine instantly whether the asphyxia is mild or severe. The child may be in a condition of apnea which may resemble mild asphyxiation, this condition being especially common in Cesarean sections. In mild asphyxia the child is rigid, blue, with turgid lips, slight exophthalmos, its pharynx and trachea are full of mucus, so that when it gasps no air can get into the lungs. The throat reacts to the finger. In severe asphyxia the extremities hang down, the surface is pale, the jaw falls, or is jerked by an occasional gasp, the throat does not react to the finger, the heart beats faintly, or is only perceptible to the ear. Anemia of the fetus and compression or hemorrhage into the brain present symptoms similar to severe asphyxia, but the treatment is the same. Morphin given the mother, especially in eclampsia, will sometimes produce narcosis in the child, which may be fatal. The three great principles governing the treatment of asphyxia, according to De Lee, are: 1, maintain the body heat; 2, free the air passages from obstruction; 3, stimulate respiration, or supply air to the lungs for oxygenation of the blood. He gives details as to these and describes the apparatus for mouth insufflation and the methods of artificial respiration. One's duty is not completed in having brought an asphyxiated child to crying. It may develop a secondary asphyxia due to atelectasis pulmonum, or there may be some pulmonary circulatory trouble in addition. When the child is partially revived one may try to expand the lungs by forced insufflations, but it should be carefully performed. There should not be too active or too persistent efforts.

102. **Treatment of Obesity.**—This fourth section of Von Noorden's article deals first with the treatment of obesity when complicated by kidney disease and he considers it fully as dangerous for patients with atrophic kidneys as for those with cardiac disease. He says many nephritic patients become too stout through improper diet and show all the signs of secondary cardiac disturbance. He prescribes in such cases a mixed diet poor in heat units, reduction of fluid taken, and advises cold rubbings; later a bath cure reducing the flesh and relieving the troublesome symptoms. In obesity complicated by chronic bronchitis there is little benefit until the superfluous fat is disposed of. In the obesity complicated by chronic articular rheumatism a marked loss of weight and removal of corpulence is an especial gain in many cases; thereby the overburdened joints are lightened and work is done along the same lines as the orthopedists follow when they make their sensible supporting apparatus bear a part of the pressure. In gout one is hard pressed as to diet. He believes that lean meat may be given, but care should be taken that plenty of green vegetables and fruit are added to the diet. There are frequently accompanying disturbances which demand a reduction cure far more than does the uric acid diathesis itself, such as kidney disease, arteriosclerosis, cardiac weakness, etc. He often thinks it would be better in these cases to speak of the misuse of alcohol as being the cause of the diseased condition instead of talking euphemistically of gout. There are many other diseases which impede locomotion besides rheumatism and gout, as the hemiplegias, etc. In these cases the reduction of superfluous fat is an advantage and is an important and urgent therapeutic problem whenever there is a prospect of helping patients by lessening the body weight. Massage and gymnastics are often brilliantly effectual. The favorable influence of reduction cures in certain forms of ischias and other neuralgias which occasionally occur in obese people, is especially to be emphasized. He has also cured a number of cases of the supraorbital and occipital variety of neuralgia by means of reduction cures, also some brachial neuralgias with anginic pains. It is impossible to say whether the reduction will prove useful or not in these cases, but success is frequent enough in his experience to justify the trial. In hysteria the conditions are difficult. Generally the patients are in a poorly nourished condition, but obese cases are not exactly rare, and it is especially those patients who develop obesity through rich diet and muscular laziness that the reduction cure begun under proper direction and carried out with increasing demands on the energy, is often the beginning of a new life with reawakening of strength and self-confidence. Such cures can only be successfully conducted in institutions. He believes that in diabetes mellitus the reduction cures are not entirely contraindicated, though diabetics bear a long-continued loss of body weight just as badly as they do a rapid one. Careful intermittent methods are chiefly to be recommended and the reduction of weight should be carried no further than absolutely demanded. In tuberculous patients we have sometimes an exaggeration of nutrition and he warns against overdoing the overfeeding in these cases. Such exaggerations are unfortunately frequent and treatment directed against the tuberculosis incapacitates the patient, because of the obesity which has ensued. He has followed up several such cases and he thinks they are not specially proof against relapses of the pulmonary conditions. They are often considered brilliant examples of success in institutions, but when they get out the downward course begins very soon. To the objection that the dangers of obesity are much less than those of pulmonary tuberculosis he answers that that is true, but one must ask whether it is necessary to drive away one enemy by courting another. In pulmonary tuberculosis it is not only unnecessary, but reprehensible, to try to attain more than a certain optimum of general condition.

103. **Puerperal Sepsis.**—The more closely the obstetrician follows aseptic methods the less frequently will the patient need the services of the surgeon subsequently. There are many conditions in which infection may cause a condition of ill health and we must not consider merely the prevention of death, says Montgomery, but the return of our patient to her normal condition and the preservation of her functions. There are two kinds of infection in childbirth—the putrefactive and the septic. The former is characterized by elevation of temperature and chills three days to a week following delivery; it is due to putrefaction of a blood clot, a portion of retained placenta or of membrane. This condition is associated with putrid or offensive lochia. It rapidly improves with the removal of decomposing tissue and the irrigation of the uterine cavity. The septic form is earlier and more insidious in its onset. The lochia are not necessarily offensive. The disease expresses itself as endometritis, salpingitis, oöphoritis, cellulitis, or peritonitis. The uterus is enlarged, sensitive to pressure, and the general condition of the patient is usually bad. There is a high continued temperature with resulting chills, profuse perspiration, and associated pain and tenderness. Secondary abscesses or pus collections may occur. The natural tendency of the surgeon is to explore and scrape the uterine cavity, but this is of doubtful service and may only open a new avenue for infection. Digital exploration and manipulation of the cavity, associated with irrigation, is of value in removing the loose debris and decomposing infected clots. It should be done with hot normal salt solution in preference to more active germicides, but followed by an iodoform gauze pack to keep the uterine walls separate and careful search should be made for any inflammatory exudate, and when it is found an incision should be made through the vaginal vault and the mass broken up and the cavity packed with iodoform gauze. Localized pockets of pus should be considered indications for an immediate operation, which may involve the uterine wall, the ovary, tube or peritoneum, and require the removal of the uterus or adnexa. Hysterectomy has been advocated and there are those who would do it in the majority of cases, but it is not only considered unnecessary by Montgomery, but frequently of no avail. Considering the rapid invasions by micro-organisms of all the tissues, it is useless. In the early stages the elimination of poison is promoted by the employment of intravenous injections of normal salt solution, and in the later stages it is a valuable means of support.

104. **Craniotomy.**—Krusen notes the unfavorable opinions as to the performance of craniotomy, but concludes that the life of the mother must be the first consideration. There are frequent conditions where it is justifiable. There is little doubt but that Cesarean section and symphysiotomy, except by an experienced physician with competent assistants, would sacrifice two lives instead of one. Circumstances alter cases.

126. **Alcoholic Intoxication and Hemolysis.**—From an experimental study on rabbits, Abbott and Bergey conclude: "1. The daily administration of alcohol per os to rabbits brings about a reduction in their circulating blood of the hemolytic complement. 2. Slight alterations in the normal alkalinity of the blood serum have no demonstrable influence on the (hemolytic) complement of the blood of alcoholized rabbits. 3. The diminished reactivating power of the blood of alcoholized rabbits is not due to the presence of small amounts of alcohol as such in the blood. 4. The administration of alcohol to rabbits induces not only a marked reduction in the complement content of their blood, but may cause, at the same time, a reduction in the specific hemolytic receptor in the blood of rabbits artificially immunized against an alien blood. 5. The diminished complement content of the blood of alcoholized rabbits renders the animal more susceptible to the toxic action by an alien blood."

132. **Serum Diagnosis.**—Sailer reviews in this article—which probably will be followed by others—the reaction between pathogenic micro-organisms and the blood serum of infected animals, noticing the Widal reaction. the reactions of the allied colon group bacilli and other micro-organisms of this group such as *Bacillus mesentericus*, *Bacillus febris gastrica*, and the bacillus of psittacosis and the bacilli of Sanarelli and Havelburg. He thinks the dysentery bacillus is also a member of the colon group, but the agglutinating reaction of some of these mentioned is not yet definitely decided. The plague bacillus agglutination has been of some value, but difficulties are

experienced on account of a sort of spontaneous agglutination which occurs. Little practical work has been done with that of cholera, probably because cholera is not epidemic among Western nations as in former years. Considerable experiment has been made for the agglutinating reaction of the tubercle bacilli that can be used clinically and Sailer gives the results. It seems hardly yet satisfactory for diagnostic purposes; it is of value only when positive, and its absence does not exclude tuberculosis. Other microbes mentioned are those of pneumonia, Malta fever, tetanus, etc. The mechanism of agglutination is not yet satisfactorily explained. The theories and researches are briefly noted. As regards the hypothetic substance by which agglutination is brought about, especially the so-called agglutinin, it has never yet been isolated. Too little is known about it to draw any conclusions excepting that in its reaction it seems to appear more resistant to ferments and that two substances are necessary in order to manifest its action. Sailer thinks it is well with our present knowledge to refrain from giving it any name that presupposes a separate identity.

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures and single case reports are omitted unless of exceptional general interest.

British Medical Journal (London), August 30.

1 On Direct Endoscopy of the Upper Air-Passages and Esophagus; Its Diagnostic and Therapeutic Value in the Search and Removal of Foreign Bodies. G. Killian, M.D.
2 A Case of Papillomatous Excrescences, Ozænic Incrustations, or Chalky Deposits, or Other Lesion Low Down in the Trachea. E. Law, M.D.
3 A Discussion on the Diagnosis and Treatment of Foreign Bodies in the Upper Air-Passages and Gullet. J. MacIntyre, W. Downie, W. T. Thomas, and Dr. Wild.
4 *A Simplified Method of Operating for Deflection of the Cartilaginous Septum. D. Grant.
5 Chronic Laryngitis; Correlation of Diagnosis and Treatment. N. C. Haring.
6 *The Connection of the Isolated Respiratory Fibers of the Recurrent with the Sympathetic and Cardiac Nerves. A. Onodi.
7 A Discussion on the Ultimate Results of Surgical Operations upon the Frontal Sinus and Maxillary Antrum. M. Lermoyez, H. Tilley, and Five Others.
8 On the Operative Cure of Laryngeal Papillomata. G. MacDonald.
9 *Bromide of Ethyl Anesthesia in Operations in the Throat. A. B. Kelly.
10 Moure's Operation for Deflected Septum. L. H. Pegler.
11 The Present State of the "Ozæna" Question. L. Grunwald.
12 A Discussion on the Etiology and Diagnosis of Ethmoidal and Sphenoidal Suppurations. L. Grunwald, H. L. Lack, and Thirteen Others.
13 Address by the President, Section of Otology. (Wm. Milligan, M.D.) The Study, Teaching and Prevention of Diseases of the Ear.
14 A Discussion on the Aims and Limitations of Intranasal and Surgical Procedures in the Treatment of Chronic Non-Suppurative Middle-Ear Disease. P. McBride, U. Pritchard, and Sixteen Others.
15 Remarks on Cholesteatoma of the Middle Ear. D. Grant.
16 On the Relation between the Formation of the Auricle of Anthropoid Monkeys and Certain Congenital Malformations of Human Auricle. F. Rohrer.
17 The Provision in London for the Education of the Deaf. A. Thorne.
18 The Treatment of Deafness of Middle-Ear Origin. C. Watson.
19 Remarks on the Anatomy of the Temporal Bone, with Lantern Illustrations. R. C. Elsworth.
20 Apparatus for Intratympanic Hot-Air Treatment of Certain Forms of Catarrh of the Middle Ear. Adolph Bronner.

Indian Medical Gazette (Calcutta), August.

21 The Postmortem Appearances in Cases of Asphyxia Caused by Drowning. Lieut.-Col. J. B. Gibbons.
22 Return of Sudden Deaths Requiring Coroner's Inquests for Five Years (from 1896 to 1900) in the City of Calcutta, with Remarks. Major C. R. M. Green.
23 Analysis of the Postmortem Examinations in the Murshidabad District During the Past Five Years. Lieut.-Col. T. G. Grainger.
24 Dilation of the Pupil in Chlorodyne Poisoning. A. Powell.
25 The Plague Commission on Haffkine's Anti-Plague Inoculation. N. H. Choksy.
26 Prevalence of Stone Amongst the Rice-Eating Population of Lower Bengal. Jadob Kisto Sen.

Hospitalstidende (Copenhagen), July 30 to August 20.

27 (No. 31.) *Fixation and Staining of Organized Urinary Sediments. P. Liebmann.—Om Fixering og Farvning af det organiserede Urinbundfald.
28 (No. 32.) Two Unusual Cases of Resection of the Intestines. S. Boysen.—Om to Tarmresektioner.
29 (No. 33.) Improved Hemoglobinometer. A. A. Meislin (Copenhagen).—Et nyt Haemoglobinometer.
30 (No. 34.) Experiences with Manipulative Reposition of Congenital Dislocation of the Hip-Joint. C. Lange.—Meddelelse om Behandlung af medfodt Hoftluxation ved ublodig Reposition efter Lorenz's Metode.

Annales de Dermatologie (Paris), July.

31 *Des altérations oculaires dans le xeroderma pigmentosum. A. Monthus.
32 Cas d'hémato-lymphangiome kystique superficiel développé sur la cicatrice résultant de l'extirpation d'un lymphangiome caverneux sous-cutané. U. Mantegazza.
33 *Results of Treatment of Lupus with Radium Rays. Danlos.—Lupus traité par le radium.
34 *Note sur l'emploi de l'adrénaline en photothérapie. De Beurmann.
35 *Traitement du prurigo de Hebra. De Beurmann.
36 Elephantiasis probablement d'origine syphilitique. Balzer.
37 Des accidents dus aux injections de cyanure de mercure dans le traitement de la syphilis. Barthélemy.

Revue de Chirurgie (Paris), August.

38 Fractures du tarse postérieur. E Destot.
39 *De l'actinomycose ano-rectale. L. Thevenot.
40 *Operative Reposition of the Head of the Femur. G. Gayet.—De la reposition sanglante de la tête fémorale dans les luxations irréductibles de la hanche, en particulier dans les luxations path. (Concluded from July number.)

Boas' Archiv f. Verdauungskrankheiten (Berlin), viii, 1 to 3.

41 (Von Leyden No.) *Intestinal Dyspepsia. Knud Faber (Copenhagen).—Ueber Darmdyspepsie.
42 *Occult Gastric Hemorrhages. J. Boas and A. Kochmann.—Weitere Beiträge zur Lehre von den occulten Magenblutungen.
43 Beiträge zur Antiperistaltik des Darms. J. C. Hemmeter (Baltimore).
44 *Ueber Heterochylie. G. Korn.
45 *Frequency and Heredity of Gastro-Intestinal Findings in Families. F. A. R. Jung (Washington).—Die Häufigkeit und Erblichkeit von Magen-Darmbefunden in Familien.
46 Hyperacidität. (Superaciditat, Hyperchlorhydria, Superaciditas chlorhydrica.) Eine klinische Studie. H. Illoway (New York).
47 Zucker (sugar), als solcher, in der Diät der Dyspeptiker. W. G. Morgan (New York).
48 (No. 3.) Ein Oesophagoscop. J. Schreiber (Königsberg).
49 Ueber Syphilis der Leber (Liver). Max Einhorn (New York).
50 Exaggeration of Reflex Spasmodic Effort to Vomit by Nasal Affections. Treitel.—Ueber die Steigerung des Würgreflexes durch Nasenleiden.

Centralblatt f. Chirurgie (Leipsic), August 9 to 23.

51 (No. 32.) *Puncture of Foreign Bodies. G. Perthes.—Ueber Fremdkörperpunktion.
52 (No. 33.) Rhinoplastik. Dreesmann.
53 (No. 34.) Zur Aetiologie der cong. Hüftgelenksluxation (Luxation of Hip-Joint). O. Bender.

Centralblatt f. Gynaekologie (Leipsic), August 9 to 23.

54 (No. 32.) Disinfectants for Obstetric Nurses. F. Ahlfeld.—Erganzungsblatt 3 und 8 zum Preussischen Hebammen-Lehrbuch.
55 Zur Verletzung der Vagina beim Coitus. Hermes.
56 *Complication of Pregnancy by Carcinoma of Rectum. Z. Endelmann.—Beitrag zum geburtshilflichen Verfahren bei Complication der Schwangerschaft durch Mastdarmkrebs.
57 (No. 33.) *Sterile Yeast for Vaginal Use. W. Albert.—Sterile Dauerhefe und ihre vaginale Verwerthung.
58 (No. 34.) Ein neues Speculum. A. Theilhaber. (Munich).
59 Was ist intraabdomineller Druck? O. Hagen-Torn.

Deutsche Med. Wochenschrift (Berlin and Leipsic), August 14.

60 *Technic and Results of Resection of the Ankle. F. König.—Methodik und Erfolge der Fussgelenksresektion.
61 *Bone Plastic Closure of Defects in the Skull. E. Hoffmann.—Ueber Verschluss von Defekten am knochernen Schädel durch der Nachbarschaft entnommene Knochenplättchen.
62 *Ueber einen Fall von Tumor der Cauda equina. F. Volhard.
63 Erythema simplex marginatum; 6 Fälle. L. Feilchenfeld.
64 Injury from "Praservesalz" (Sodium Sulphate). Kionka.—Ibid. Byk.
65 Favorable Report on Bismuthose. W. Lissauer.—Bismutose bei Diarröen kleiner Kinder; 30 Fälle.

August 21.

66 Determining the Outlines of the Heart with Actinoscopy. E. Grunmach and A. Wiedemann.—Ueber die aktinoskopische Methode zur exakten Bestimmung der Herzgrenzen.
67 Beiträge zur Frage der gegenwärtigen Verbreitung der Malaria in Nordwestdeutschland. P. Mühlens. (Concluded from No. 33.)
68 Sternum, Brust-Aorta und Wirbelsäule (Spine) im Roentgen-Bild. Max Levy-Dorn.
69 *Simultaneous Erysipelas and Scarlet Fever. P. Haller.—Rose und Scharlach, gleichzeitig bei derselben Person.
70 Medico-historische Miscellenen. T. Distel.
71 Beitrag zur Pneumonie-Statistik. E. Müller.
72 Ein einfacher Apparat zur Colpeurynter-Massage. Holz.
73 Electric Light Bath. Axmann.—Zum elek. Luftbad.

Klinisch-Therapeutische Wochenschrift (Vienna), August.

74 (Nos. 31 and 32.) *Thiocol and Sirolin. S. Drago.—Klin. exp. Untersuchungen über die Wirkung des Thiocols und des Sirolins.
75 Gastrische Crisen als erstes Symptom der Tabes Dorsalis. M. Lauterbach.
76 (No. 33.) Two Cases of Recovery After Putrid Affections of the Lungs. A. Weber.—Lungenabszess nach Fremdkörper; Lungenbrand nach Hufschlag gegen den Rücken.
77 *Ueber die Wirkung des Antistreptococcen-Serums. Tavel. (Commenced in No. 28.)

Muenchener Med. Wochenschrift, August 12.

78 *Study of Secretion of Hydrochloric Acid. M. Cloetta.—Zur Kenntniss der Salzsäuresekretion.
79 Ueber die Erzeugung hämolytischer Amboceptoren durch Serum-*Injektion.* P. T. Mueller.

80 *Zur Behandlung der sogen. "plastischen Induration" der Corpora cavernosa Penis. E. Galewsky and W. Hübener.

81 *Obstetrics in Case of Contracted Pelvis. Krönig.—Geburtsleitung beim engen Becken.

82 Ueber ein neues Abführmittel, "Purgatin." K. v. Hösslin.

83 * Infectious Diseases. G. Kös- Beziehungen der Chorea minor

84 Turpentine in Typhlitis. M. Mayer.—Erfahrungen über die Anwendung von Terpentinöl und verwandten Mitteln bei Blinddarmentzündung.

85 Fatal Hemorrhage in Bursa Omentalis Simulating Acute Intestinal Occlusion. K. Grassmann.—Tödtliche Blutung in die B. o.

86 Zur Toxikologie des Phosphors. K. Stich.

87 Zur Cystoskopischen Technik. F. Schlagintweit.

88 Zum Schwinden der Patellar-Reflexe bei Pneumonie. H. Lüthje.

89 Martial's Satires on the Profession. T. W.—Ein alter Aerztefeind.

Janus (Amsterdam), August.

90 The Neux Family in Surgery. P. Dorveaux.—La rasse des Neux, maitres chirurgiens de Paris.

91 Pathologisches aus Alt-Peru. R. Lehmann-Nitsche.

92 Studies in History of Medicine in Russia. Lachtin (Moscow).—Studien über die Geschichte der Medicin. (Commenced in No. 7.)

Giornale della Accademia di Medicina (Turin), June-July.

93 Sopra un caso di Leucanemia. G. Mattirolo.

94 Su la sutura zygomatico-maxillaris. B. Nicola.

95 Experimental Study of Intoxication with Carbon Monoxid. C. Foa —Ricerche sul sangue avvelenato con ossido di carbonio

96 Ricerche sull'azione chimico-fisiologica dei nucleoistoni e dei nucleoproteidi. A. Herlitzka.

97 Sul momento di rotazione del muscolo flessore superficiale del dito medio rispetto all' articolazione interfalangea. Z Treves.

98 Sulle alterazione istologiche della cheratosi pilare. S. Giovanni.

99 Gastrophilus Equi. E. Perroncito.

100 Coccidium jalinum ed il microsporidium polyedricum Bolle nel uomo (in Man). E. Perroncito.

101 Contributo allo studio dell' immunizzazione per l'arsenico. L Scofone and A. Brinda.

102 L'acido fosfocarnico nella sostanza cerebrale. A. Panella

Medicinskoe Obozryenie (Moscow), lvii, 3 to 8.

104 (No 3) *Contusions of the Kidneys. Sarytcheff.—O podkozhnykh povrezhdeniyakh potchki

105 K etiologii aneurism aorty. Segaloff.

106 (No 4) Patologo-anatomie pri tetaniya. Tchernysheff.

107 Value of Suprarenal Extract in Rhino-laryngology. Radtzikh Ekstrakt nadpotchetchnikov v rino laringologii.

108 (No. 5) Operative Treatment of Rupture of the Uterus During Delivery. Uspenski.—O chir. lyetchenii razryvov matki vo vremya rodov

109 Phototherapy. Tzyekhanski.—Svyetoletchenie

110 Theoretic Foundation for Phototherapy Spetoff.—Teoretitcheskiya osnovaniya lyetcheniya svyetom.

111 Stain for Milk and Blood. Vysotzki.—K okraskye mokroty i krovi.

112 (No. 6) *Cause and Treatment of Alveolar Pyorrhea. Znamenski —Alveolyarnaya piorreya.

113 Tuberculosis of Bladder and Prostate. Cohn.—O bugortchatkye motchevova puzyrya i predstatelnoi zhelezy.

114 (No 7) Cancer of the Pancreas. Bazhenoff.—O rakovom novoobrazovanii v podzheludotchnoi zhelezye.

115 (No. 8) Two Cases of Cholesteatoma in the Middle Ear. M. M. Resser —O cholesteatomakh srednova ukha.

116 Differentiation of Inflammation in Antrum of Highmore with Stein's Needle. Dempel.—O raspoznavanii Highmoritov pri pomoshtchi iglii Steina

117 Two Cases of Elephantiasis Due to Syphilis Pokrovsky.—Dva slutchaya slonovosti v zavisimosti ot syphilisa.

Rousskii Vratch (St. Petersburg), May to August.

118 (No 20) Study of Development of Throat Based on Case of Congenital Anomaly. N. A. Batueff.—Articulatio hyothyroidea anomala cong.

119 *New Sign of Tetany. A. I. Solovieff.—Phrenicus-phaenomenon.

120 (No. 21.) *Stab Wounds of the Abdomen. B K. Finkelstein.—O pronikaiushtchikh kolotoryezanykh ranakh bryushnoi polosti. (Commenced in No. 18.)

121 (No 22.) Study of Ovarian Cysto-Adenomata. D. D. Popoff.—Proiskhozhdenie sosotchkovykh kistoadenom i novye dannya v polzu paraophoralnova utcheniya. (Commenced in No. 21.)

122 *Differential Diagnosis of Appendicitis in Women. M. I. Rostovtzeff.—*Peritiphlit u zhenshtchin.* (Commenced in No. 20.)

123 Action of Toxins on Unicellular Organisms. B. V. G. Korentchevski.—Dyeistvie yadov na odnoklyetotchnykh zhevotnykh (Commenced in No. 21.)

124 (No. 23.) Chronic Prostatitis. C. Posner.—Raspoznavanie etc. chron. vospaleniya predstatelnoi zhelezy.

125 *Suprapubic Lithotomy in Children. P. Tikhoff.—O vysokom kamnisyetchenii v dyetskom vozrastye. (Concluded from No. 22.)

126 Leprosy in Astrachan. V. A. Virshillo.—Prokaza.

127 (N a Metabolism of Alcoholics. A. V. Pel. veshtchestv u alkoholikov.

128 (Test for Uric Acid. A. Y. Kalatchnikoff.

129 *Malaria in Turkestan. S. A. Mark.—Iz nablyudenii nad malariei v Turkestan. (Concluded from No. 21.)

130 (No. 26.) Syphilis of the Heart with Marked Dilatation of Pulmonary Artery. K. E. Wagner.—Slutchai siphilisa serdtza. (Concluded from No. 25.)

131 (No. 27.) Diphtheria and Diphtheria Bacilli in Scarlet Fever. I. A. Shabad.—Diphtheriya i diphth. palotchka pri skarlatinye.

132 Prophylaxis of Syphilis. Z. Y. Eltzina.—K voprosu o rassherenii myer borby s siphilisom.

133 Cadaveric Rigidity of Dead Fetus in Uterus. L. A. Gusakoff.—O trupnom okotchenyenii unershikh utrobnykh mladentzev.

134 (No. 29.) Influence of Toxins of Diphtheria and Tetanus on the Elements of the Blood. G. G. Kurkharzhevski.—O vliyanii diphtheriinova i tet. tokcinob.

135 Transplantation of the Cornea. G. I. Suroff.—K voprosu o peresadkye govoritzy.

136 Present Status of the Question of Bovine and Human Tuberculosis. H. H. N. N. Mari.—Sovremennoi sostoyanie voprosa o cootnoshenii bugortchatki tchelovyeka i zhevotnykh. (Concluded from No. 27.)

137 (No. 30.) *Operation for Epispadia. A. A. Muratoff.—K voprosu ob obrazovanii muzhskoi uretry y bolnoi epispadiei, soedinnoi s rasshtcheplenlem lonnova soedineniya.

138 Experiments with Toxin of Glanders.—A. M. Maksutoff.—Malleo-toksina.

139 Casuistic of Extragenital Syphilis. M. A. Tchlenoff.—K kazuistikye vnyepolovova syphilisa.

140 (No. 31.) *Pathogenesis and Treatment of Eclampsia. V. V. Stroganoff.—O pathogenezye i lyetchenii eklampsii. (Commenced in No. 27.)

141 *Acetonuria in Gynecologic Affections. M. P. Krivoshein.—K voprosu ob acetonurii pri zabolyevaniyakh zhenskova polovova apparata.

142 Experimental Study of Death After Injection of Foreign Blood. L A. Tarasevitch.—O smerti immunisirovannykh zhevotnykh.

143 Nineteen Cases of Inguinal Hernia Operated on According to Roux. V. I. Hedroitz.—19 slutchaev korennoi operatzie bedrennoi gryzhi po sposobu prof. Roux. (Commenced in No. 28.)

144 (No. 32.) *Intrarectal Urethral Plastics in Gynecologic Practice. V. S. Gruzdeff.—*Uretroplastika po ideye Subbotina v gyn. praktikye.*

145 Quantitative Determination of Alexins in Human Serum. G. A. Guseff.—K voprosu o kol. opredyelenii aleksinov v syvorotkakh lyudei.

146 *Pathology and Treatment of Progressive Deafness. M. V. B. Berezovski.—K voprosu o pat. i therapii narostayushtchei glukhoty. (Commenced in No. 30.)

4. **Septal Deflection.**—The method here suggested by Grant is a combination of portions of two other methods and consists in: 1. Cocainizing both sides of the septum. 2. Straightening and transfixing with the needle. 3. Administering nitrous oxid gas. 4. Cutting through the cartilage by means of Moure's shears, horizontally below the deflection, then obliquely in front of it and above it, parallel to the ridge of the nose, the incisions not meeting below and in front. 5. Manipulating the cartilage at the incisions so as to encourage overriding. When the deflection is accompanied by any considerable degree of thickening this should be shaved off beforehand, preferably at an interval of a couple of weeks, though it may be done at the time.

6. **The Laryngeal and Cardiac Nerves.**—Onodi has investigated the course and connections of the cardiac fibers in the sympathetic and finds an extraordinarily intimate relation which he describes as follows: "The connection of the superior laryngeal nerve with the upper cervical ganglion of the sympathetic and with the rami cardiaci superiores, which arise from the latter, is known, as is also the connection of the superior laryngeal nerve with the lower cervical ganglion of the sympathetic; the connection of the external branch of the superior laryngeal being much closer with the upper cervical ganglion of the sympathetic and the superior cardiac cervical. The external branch of the upper laryngeal nerve sends off a direct cardiac branch of connections to the upper cervical ganglion of the sympathetic and to the upper cardiac nerve. These anatomic conditions form in man an exact analogue to the depressor nerve found in animals. In regard to the inferior laryngeal we know its connections with the upper cervical ganglion of the sympathetic and with the superior cardiac nerve. Of great significance is the observation of Lenhossek, according to which the inferior laryngeal nerve arises from a ganglion, whilst the ganglion stands in connection with the pneumogastric by means of a thin root. The lower laryngeal is connected with the lower cervical ganglion of the sympathetic, and further, with the cardiac branches, which take their origin from the middle and lower cervical sympathetic. . . . It is known that in the trunks of the sympathetic besides the vasomotor and trophic, there are cerebrospinal, sensitive, and motor fibers. My investigations have shown that the cerebrospinal nerve fibers of the rami communicantes run in the trunk of the sympathetic according to a well-defined system. In the

upper part of the thorax and in the neck the larger part of the cerebrospinal fibers of the sympathetic run upwards and only a smaller part downwards, whilst in the rest of the thorax and in the abdomen just the reverse is the case. The sympathetic constitutes the morphological basis in the known connections for the course of the fibers and their intercommunication, as they are of different origin and different destination. Physiology has until now shown the presence of the depressor fibers and the cardiac branches originating from the upper laryngeal nerve, and my experiments have shown that in the dog the irritation of the sympathetic trunk between the lower cervical and first thoracic ganglion, as also of the communicating branches of the brachial plexus, will produce a retraction of the vocal cords of the same side. Beyond these observations the morphologic facts mentioned have received no pathologic or physiologic explanation. I may in particular draw attention to the intimate connection before mentioned which exists between the isolated respiratory nerve fibers of the lower laryngeal nerve and the sympathetic and the cardiac branches. The morphologic foundation is laid in the before-mentioned single facts, showing an exchange of nerve fibers of different origin and destination, but the isolation of these fibers and the investigation of their destinations still forms a subject the difficult solution of which is reserved for future physiologic and pathologic inquiry."

9. **Ethyl Bromid.**—This anesthetic has been used by Kelly 1200 times in tonsillotomy and operations for adenoids, polyps, etc., almost all in young persons or children. He insists on attention to the respiration during the administration, not prolonging the operation by repeating the dose over twice or thrice, and the use of a pure article. Its advantages are enumerated by him as follows: "No special apparatus is needed for its administration, narcosis is rapidly produced, the vapor does not irritate the respiratory mucous membrane, the upright position of the patient is permissible, there is quick return to consciousness, the after-effects (vomiting excepted) are unimportant or nil, and the danger is insignificant. . . . Another advantage which will commend itself to those who can not always obtain the services of a skilled anesthetist is that the administration can be superintended by the operator, who, sitting facing the patient, is in the best position to note the progress of the narcosis. As a time-saving agent bromid of ethyl is invaluable in dispensary practice. I have often operated on six or seven patients in forty or fifty minutes, and with organized assistance a dozen cases might be undertaken in an hour, as is accomplished by De Roaldes." Its disadvantages are the frequent impurities and the instability of the drug, the persistence of muscle tonus and the rather frequent after-vomiting. In adults the occasional after-excitement is also a disadvantage. Kelly says, however: "By virtue of its safety and convenience bromid of ethyl is entitled to a place among the anesthetics in daily use. Its position is between nitrous oxid and chloroform, ether, etc. Although handier than nitrous oxid, the latter, on account of its almost absolute safety, should be preferred when very brief anesthesia will suffice. On the other hand, chloroform, ether or one of the various mixed anesthetics should be resorted to when prolonged narcosis is necessary. A single administration of bromid of ethyl gives anesthesia lasting on an average a minute and a half, and this in conjunction with other qualities of the drug render it, I believe, the best anesthetic we at present possess for the removal of tonsils and adenoids."

27. **Fixing and Staining Sediment of Urine.**—Liebmann recommends a mixture of 2 gm. methylene blue dissolved in 100 gm. of a 10 per cent. solution of formalin. Two to four drops are dropped into the centrifugalizer tube, on top of the sediment, and left a few minutes. The tube is then filled up with water and left a while for the salts to dissolve, then centrifugalized again, when the formed elements are ready for the microscope. The results are exceptionally fine and durable.

31. **Ocular Alterations in Xeroderma Pigmentosum.**—Monthus mentions that about a hundred cases of xeroderma pigmentosum are on record. The frequency of the development of the lesions in the region of the eye attracts attention. These ocular lesions range from pigmented patches, dystrophic lesions and telangiectasia to benign and malignant tumors. The first manifestations of the affection may appear in the region of the eye, and malignant evolution is particularly rapid in this locality. In two cases recently observed by him, the xerodermic alterations included tumors of the lid and cornea, ectropion and xerodermic lesions of the conjunctiva in one case and in the other both lids were affected, with pannus of the right eye and epithelial tumor in the other. The patients were sisters, 15 and 13 years old. He describes both cases in detail. Treatment can be only prophylactic and symptomatic. Prompt and total extirpation is indicated in case of neoplasm of the lid, conjunctiva or cornea. Panas has demonstrated that ablation of the tumor and cauterization of its point of implantation will usually suffice, without necessity for enucleation of the eyeball.

33. **Results of Treatment of Lupus with Radium Rays.**—Danlos has treated five cases of lupus with the rays generated by radium. The results were remarkably favorable and there is evidently a future for this method of treating lupus when radium becomes less rare and expensive than at present. The plate of the metal was applied directly to the skin and one case of old inveterate verrucose lupus was completely transformed after nine applications. The verrucose protuberances have entirely disappeared without leaving a trace and have been replaced by a smooth cicatrix of good appearance. The radium was applied seven times for twenty-four hours at each sitting. It was applied once for 72 hours at one point and again for 120 hours at another and both these points developed a typical *x*-ray ulceration which has persisted for six months, with lancinating pains. The skin of the parts treated also became so stiff that flexion of the joints of two fingers has become impossible. The radium was estimated at 19,000 units of activity. In another case radium of the same strength was applied once for 36 hours to symmetrical lupus of the cheeks on a man 50 years old. The patch treated was modified by the application in striking contrast to the rest of the lesion around. Under the radium there is now a smooth, superficial, thin cicatrix while elsewhere the lupus exhibits the usual reticulated, swollen aspect. Another patient developed an ulceration which healed after a comparatively short time under the application of plantain leaves which also proved beneficial in another case. In still another patient the contrast is equally striking between the smooth white uniform cicatrix on the small patch covered by the plate of radium and the cheloid roughnesses around it. Danlos' first attempts with radium of weak power had the same prompt curative effect, but recurrence soon followed, while with sheets of 2500 and 19,000 power there has been no recurrence to date, more than a year in some cases. Curie states that radium of 1,500,000 power is obtainable. Brief applications of about 19,000 seem most promising. The rays emitted by the radium are evidently a combination of cathode and *x*-rays. As the cathode rays can be deflected by a magnet, it may be possible to eliminate them, if they prove to be the cause of the ulcerations. Brocq endorsed Danlos' communications as a great advance in the treatment of lupus. The results are cosmetically as favorable as those obtained by phototherapy or scarifications while the course of treatment is very much shorter than the former.

34. **Adrenalin in Phototherapy.**—De Beurmann has found that the application of a 1 per 1000 solution of adrenalin allowed the application of phototherapy without the necessity of a compressor to expel the blood from the part. The sitting lasted an hour and the blood did not return to the part during this time.

35. **Treatment of Hebra's Prurigo.**—De Beurmann has had a patient under observation for seven years, a typical case of this affection. He recently commenced treating him after the failure of all other measures by the daily and permanent application of a salve made of 12 parts camphor, 15 parts tar, 8 parts sulphur, 3 parts chaulmugra oil and 62 parts vaselin. The improvement has been astonishing, the skin has become flexible and the patient is freed from his discomfort.

39. **Ano-Rectal Actinomycosis.**—Thevenot reviews 15 cases of ano-rectal actinomycosis. Three of the patients are temporarily cured; 7 have died and 1 has been under treatment for three years. None was permanently cured. He warns against prolonged surgical procedures, curetting, scraping, etc., in deep, extensive actinomycosis with cavitation. Intervention should be limited to opening the abscesses; anything further merely whips up an otherwise torpid process and hastens the fatal termination. Death is due to the protracted suppuration and also probably in part to some specific intoxication from the ray fungus.

40. **Operative Reposition of the Head of the Femur.**—Gayet tabulates the details of 29 cases of reposition of traumatic luxations and describes 7 others of pathologic luxations including one in his own experience. Operative reposition of old and irreducible luxations he considers an excellent method of treatment which has established its usefulness and should take rank as the classic method of treating such cases. It is not in itself a serious intervention while the results far surpass those obtained by other means. Restoration of function is sometimes ideal, almost always with mobility allowing a nearly normal gait. It prevents shortening of the limb or remedies it if existent. External incision along the trochanter is generally ample, contrary to the general opinion. The same rules apply to pathologic luxations consecutive to acute diseases, the lesions in them resemble remarkably those of traumatic lesions. On the other hand, in the luxation of hip disease, operative reposition is rarely indicated on account of the general condition, the alteration of the bones and the danger of rearousing a slumbering process, but it may prove useful in a few special cases. He describes the technic, etc.

41. **Intestinal Dyspepsia.**—Faber believes that a certain form of well-developed and persisting dyspepsia originates in disturbances in the intestines, although the symptoms are usually attributed to the stomach. He describes three cases in which there had been constipation for some months, either neglected or treated with laxatives. It was followed in time by symptoms of dyspepsia, cardialgia, eructations, anorexia, nausea and vomiting, with severe nervous symptoms, headache, depression, insomnia, and in one case vertigo. These symptoms had lasted for several months to eight years. Efforts to treat the stomach were abandoned as the motor and chemical functions were found to be normal, and the patients were placed on a diet rich in cellulose with small doses of castor oil at bedtime. The rapid and complete abolition of all the symptoms confirms the assumption that the dyspepsia was exclusively intestinal. Fat heavy foods induced cardialgia in these cases as in gastritis. In 2 other cases the symptoms were practically the same, but there were also indications of hyperacidity, which vanished with the other symptoms when the intestinal functions were regulated. The hyperacidity he believes was due to reflex action from the deranged intestines. This assumption is confirmed by the fact that the same clinical picture is observed in cases of tape-worm, which causes the same symptoms above described. The burning, gnawing feeling of hunger localized in the stomach and developing a few hours after a meal, supposed to be characteristic of hyperacidity, is also characteristic of the presence of tenia. It vanishes completely with the expulsion of the worm. He examined the gastric secretion in 11 cases of patients with tenia saginata. In 5 the secretion was normal, in 6 it was excessive. In 4 of the latter the expulsion of the worm restored conditions to normal. The other 2 were probably not long enough under observation for the drop in the secretion to be noted. The hyperchlorhydria in case of a tenia is evidently due to the mechanical irritation of the large creature in the intestines, as he noticed in several instances that it diminished remarkably after the expulsion of a large portion of the worm, although the head remained. It increased again parallel with the continued growth of the worm. He has repeatedly noted that administration of filicis in such cases, to expel the parasite, has no effect *per se* on the secretion in the stomach. The gastric symptoms in all these cases should not be ascribed to the stomach any more than every case of headache and vertigo should be ascribed to a cerebral affection. He adds that fully one-half of all cases of dyspepsia are intestinal. In Denmark all obscure cases are diagnosed as catarrh or ulcer of the stomach; in other countries they are referred to nervous dyspepsia or neurasthenia. The physician should inspect the stool of his patient or instruct him how to examine them for indications of constipation, erosions, etc. An actual gastric affection must be excluded before incriminating the intestines exclusively. Pains in the stomach immediately after a meal are more suggestive of ulcer, while those induced by the intestine can be in the same place and fully as severe, but they do not occur until several hours afterward, as a rule. The localized pain in the latter case is lower down. The physician should seek to discover and remedy the primary cause for the constipation. If one can not be found he should be guarded in his prognosis. Faber has a number of times observed obstinate constipation as the initial and for a long time the only symptom of a carcinoma of the stomach. Nerve strain is a frequent cause of constipation and the dyspeptic symptoms develop more readily in such subjects. Milk and milk dishes and laxatives should be avoided. The patient should be warned to guard against recurrence of the constipation and especially hard, knobby stools. He should resume at once the small doses of castor oil on retiring, supplemented, possibly, by a daily enema of oil or water, and eat stewed fruits and Graham bread, etc. The intelligence of the patient is, therefore, an important factor in the permanent cure. A milk diet is a valuable guide as it aggravates intestinal dyspepsia, while it benefits gastric affections.

42. **"Occult" Gastric Hemorrhages.**—The Journal published (Vol. xxxvi, p. 1670) Boas' communication in regard to the presence of minute admixtures of blood with the stomach contents or feces, only to be detected with the Weber test for blood. He never found the blood in cases of gastritis anacida or subacida, nor with hyperacidity, hypersecretion or benign ectasia. On the other hand, these "occult hemorrhages" were occasionally detected in cases of ulcer of the stomach and consecutive stenosis of the pylorus, and they were found constantly in all cases of gastritis with stenosis and of carcinoma of the stomach. Further experience with 257 cases investigated has demonstrated that occult hemorrhages are extremely important as an aid for the diagnosis of carcinoma in dubious cases. He affirms that the constant absence of minute hemorrhages in the stomach or stools, with more or less normal motor function and absence of hydrochloric acid findings, can be accepted as evidence against a carcinoma, and may differentiate a chronic anacid ulcerative gastritis or other lesion which may otherwise present the same clinical picture. The discovery of these occult hemorrhages may also serve to warn of impending serious hemorrhage which may be averted by appropriate treatment. They occur in three conditions, in cases of ulcer, of carcinoma and of severe, non-malignant motor disturbances, both periodical and permanent. The greater the motor function the less the hemorrhages as a rule. Error from hemorrhage due to the introduction of the sound or other cause can be avoided by investigating the feces.

44. **Heterochylia.**—This is the term applied by Hemmeter to the suddenly varying condition of the gastric secretion, from normal acidity to hyper- or an-acidity, which occurs principally in nervous dyspepsia. Korn reports 12 cases observed at Boas' clinic. The variations in the secretion were of purely nervous origin in 11, although some of them were cases of gastritis or ulcer. In one the history was that of hyperchlorhydria, but repeated investigation after a test breakfast revealed anacidity. Einhorn has observed six similar cases. Korn suggests that possibly hyperchlorhydria was actually the rule, but that dread of the sound or other cause may have exerted an inhibiting influence on the secretion of hydrochloric acid. In case of its absence and suspicion of carcinoma, discovery of occult hemorrhages may decide the diagnosis.

45. **Frequency and Heredity of Gastrointestinal Findings in Families.**—Jung reviews 597 cases of gastrointestinal cases in his experience. Hyperchlorhydria was evident in about a third, and gastroptosis and enteroptosis (in women) in

about one-fourth; in men, about 3 per cent. Atony was noted in 10.7 per cent. He had occasion to examine more than one member in 40 families and in 65 per cent. the affection was duplicated. Out of 27 families with enteroptosis, repeated cases occurred in 48 per cent. Out of 25 families with superacidity, repeated cases occurred in 40 per cent. Out of 19 with subacidity, repeated cases occurred in 2 per cent., while in 19 families with normal acidity, it was found normal in 31.5 per cent. Thus an average of 23 families had duplicate cases of their characteristic gastric analysis. The average frequency of duplicate cases of all the affections mentioned was 34.5 per cent.

48. **Improved Esophagoscope.**—Schreiber illustrates the esophagoscope with which he has been very successful in the last few years. He inserts it with the patient seated and obviates the usual difficulty of obstruction of the view by mucus or other substances in the esophagus, by aspirating them through a small supplementary tube attached to the outside of the esophagoscope. By this means no time is wasted and he can proceed leisurely with his inspection of the walls. He uses a tube 10 to 15 mm. in diameter for adults.

51. **Puncture of Foreign Bodies.**—Perthes expresses surprise that no one has previously called attention to the valuable information to be derived in locating a foreign body by sticking a needle into it. He uses a lance-shaped needle about the size of a Pravaz, and after inspection with the fluoroscope, he inserts the needle until it touches the foreign body, and then leaves it as a guide for the operation. As soon as the shadow of the needle and of the foreign body remain in contact when the screen is moved around, there can be no further question as to the location of the foreign body and the needle leads directly to it.

56. **Pregnancy Complicated by Carcinoma of the Rectum.**—Endelmann was able to collect only 13 cases of this combination. In 7 the child was extracted by Cesarean section. The carcinoma tissue is very friable and 2 cases are known in which the soft parts involved in the encroachment of the neoplasm in the vagina were extensively lacerated during the extraction of the fetus, although very little force was used. Cesarean section is therefore preferable in some cases as easier and less dangerous than vaginal delivery. When the carcinoma is operable it should be removed as soon as possible. Petersen has reported a case in which the neoplasm was removed by resection of 14 cm. of the rectum after six months of pregnancy. Abortion followed the fourth day and death the fifth. The operative wound was infected in this case. Small tumors situated low down can probably be removed without danger or trouble. Under other circumstances it is advisable to terminate the pregnancy regardless of its duration, before undertaking the removal of the neoplasm. The hyperemia of the organs in the small pelvis would certainly favor hemorrhage more than in non-pregnant subjects, while the fetus would be compromised by so severe an operation as removal of a carcinoma. He induced abortion in a case of this kind at the seventh month. The patient was a iii-para, 32 years old. The child died an hour after colpeurynter delivery. After complete recovery, nearly two months later, the carcinoma in the rectum was removed according to Rehn's vaginal method and the patient made an uneventful recovery. Three similar cases have been published.

57. **Sterile Yeast for Vaginal Disinfection.**—Albert reiterates his former assertions in regard to the great value of yeast as a "physiologic disinfectant for the vagina." Obstinate vaginal discharges and erosions of the portio diminished at once and were completely cured in the course of five or six injections in nearly every case. The vagina restored to normal conditions, it is easy to cure the entire genital catarrhal affection by cauterizing the interior of the uterus throughout with a 30 to 50 per cent. solution of formalin. His experience has been extensive with this method of treating genital catarrh and he has always found it extremely satisfactory. He also uses yeast to disinfect the vagina preparatory to operations on the genital organs or a laparotomy. It is injected and left for twelve hours and rinsed out immediately before the operation. This spares the patient the ordinary preparatory measures which are always more or less annoying. It also saves the epithelium of the vagina from the injury of the vigorous disinfecting measures otherwise in vogue, and reduces the danger of hemorrhage as there is none of the usual resulting hyperemia of the parts. The subject must recline while the yeast is working, and for this reason it is usually preferable to make the injection at night. He prefers the "sterile Dauerhefe" or permanent yeast put up by Anton Schroder, Landwehrstrasse 45, Munich, for less than 75 cents per 100 c.c. Albert reports that 62 women prepared for laparotomy and 53 for operations on the vagina were disinfected with this yeast and the results were strikingly favorable, especially in case of colporrhaphy.

60. **Technic and Results of Resection of the Ankle.**—König refers to a work recently published in Langenbeck's *Archiv* by one of his former assistants, Mass of New York, reporting the results of 200 operations on the foot and ankle. In 80 the intervention was along the lines advocated by König, and in the 44 followed for several years the patients can all walk, with a usable foot. He thinks that such favorable results are conclusive testimony in regard to the value of his method of intervention. By far the largest majority of the bone foci occur in the astragalus and most of these are located in or near the head. Synovial tuberculosis also usually develops on the anterior aspect of the joint. For these reasons he makes two long incisions on the lateral front aspect of the ankle, 2 to 2.5 cm. long, extending nearly to the margin of the internal and external malleoli and downward to the scaphoid on one side and to the sinus tarsi on the other. This allows ample access to the astragalus and it can be entirely removed if necessary and the adjoining bones scraped or slices chiseled off. He drives the chisel entirely through the bone before separating the slice to be taken off. This is much easier in diseased bones than on the cadaver. Tuberculous lesions in the adjoining tendon sheaths are easily removed by this method. After the resection the wound is sutured, leaving a short drain or scrap of gauze on each side and the foot is then placed at a right angle and wrapped in a bandage that soon stiffens (Moospappen) forming a shoe which is left for two or three weeks. After the drains are removed, a plaster cast is applied and left as long as possible.

61. **Bone Plastic Closure of Defects in the Skull.**—Hoffmann has used his method a number of times in the clinic and thoroughly tested it on animals. The soft parts are pushed back from the edge of the defect on one or more sides, including the periosteum, exposing the bone for 2 or 3 cm. A piece 1 to 4 cm. square is then chiseled out and applied to the defect with the outer, smooth side in. If there are fragments of bone left from the traumatism or other cause of the defect they can be utilized if sure of asepsis, otherwise not, as plenty of aseptic bone material is at hand around the lesion. The soft parts are replaced and oiled silk applied. The smoothness of the side of the bone turned toward the dura and its shape are important factors in the smooth healing. He describes a case of old traumatism of the skull in a boy, treated by this method, with complete success.

62. **Differentiation of Tumor in Cauda Equina.**—Volhard remarks that only one case is on record of a successfully diagnosed and operated tumor in the cauda equina. The symptoms were two years of pain strictly localized in the middle of the sacrum, with pain on pressure, the rectus femoris on both sides weak and emaciated, transient paresis of bladder and intestines, diminished tendon reflexes and sexual functions, tendency to decubitus on one side, lumbar kyphosis, slight motor disturbances, sensibility intact. Laquer diagnosed a neoplasm in the sacral canal compressing the cauda, and Rehn found on operating a cavernous lymphangioma extending from the middle of the sacrum into the spinal canal and compressing both cauda equina and dura. The symptoms in the present case commenced with disturbances in micturition and sexual functions, dilatation of the bladder and secondary pyelitis, with secondary dyspeptic disturbances, dryness of the skin and mucous membranes, slight loss in sensibility, motor disturbances in the

left sciatic domain, abolition of reflexes except knee-jerk and cremasteric reflex and lax paralysis. The onset of the trouble was very slow and gradual. A benign neoformation of the cauda equina close to the conus was diagnosed and operation decided on, but the patient postponed it a few days while he attended to some business. When he returned fresh acute nephritis had developed and intervention was no longer possible, and he died with symptoms of uremia. The autopsy disclosed as anticipated a glioma close below the conus, compressing the roots of the cauda against the lumbar vertebræ. Volhard gives in elaborate tabulated form a comparison of the symptoms of this portion of the spine.

69. **Erysipelas and Scarlet Fever in a Single Subject.**—Haller assumes that the erysipelas and scarlet fever in the case observed could not have been both caused by the streptococcus. He thinks it is absurd to suppose that part of the streptococci could have devoted themselves to inducing scarlet fever and part to the erysipelas. He observes that the two diseases seemed to have a reciprocal attenuating action on each other, which corroborates the assumption that an intercurrent erysipelas may have a favorable influence on another disease.

74. **Thiocol and Sirolin.**—Thiocol is a derivate of guaiacol, and sirolin is its syrup preparation. It possesses the properties of guaiacol without its disagreeable by-effects. It is a soluble powder, the ortho-guaiacol sulphate of potassium, and clinical experience is demonstrating its great value in the treatment of tuberculosis. Drago, besides testing it in the clinic, has been conducting experimental research with it on dogs. The results demonstrated that thiocol increases the number of red corpuscles and the proportion of hemoglobin. The leucocytes increase at the expense of the polynuclears. The thiocol further enhances the alkalinity of the blood, the serum albumin progressively increases in amount and it has an unmistakably favorable influence on the organic chemistry in general.

77. **Action of Antistreptococcus Serum.**—Tavel reports the course of 46 cases of various affections treated with antistreptococcus serum produced at the Institute for Research on Infectious Diseases, at Berne, of which he is director. He immunized the horses by injections of cultures derived from severe infections in man, phlegmons, otitis media, ostitis nasi, puerperal fever, gangrenous erysipelas, appendicitis, etc. He used new cultures without passages through animals, which Marmorek considers indispensable, but which he thinks are not logical. The serum was applied in 11 cases of puerperal fever, 12 of erysipelas, 8 of pneumonia, 1 of appendicitis, 4 of staphylococcus infection, etc., a total of 46 cases. He attributes the recovery in many cases to the prompt use of the serum which proved eminently beneficial in some but was absolutely ineffective in others of the same disease. The effect was marked in a case of recurring erysipelas which had led to elephantiasis of the thigh and scrotum. The attacks recurred at times nearly every week, accompanied by high fever, the affection dating from 1892. Serum treatment was instituted in 1900, and 10 c.c. of the serum were injected as a prophylactic measure every fortnight and the dose repeated when symptoms of recurrence developed. The recurring attacks became gradually more and more attenuated and the intervals longer, the general health much better. There has been no recurrence since December, 1901, and the general health is highly satisfactory. The effect of the serum was remarkable also in some cases of meningitis, but it failed in another case complicated with erysipelas. In 3 cases of old streptomycosis of the lungs, the effect of the serum was promptly beneficial, and it proved brilliantly successful in 2 cases of phlegmon. 1 of an appendicular abscess, and 1 of metastatic infection after an angina, with rheumatism, endocarditis and nephritis. No remedies in the latter case had accomplished any results, but the temperature began to decline at once after serum treatment was commenced and subsided to normal after the third injection. Another case of puerperal metastatic infection was notably improved. Tavel's experience indicates that the streptococcus serum has a favorable influence even on staphylococcus infection. The variability in its action is still a mystery. Is it due to a lack of cytases, of leucocytes or merely to a lack of amboceptors which it may be possible for us to supply?

78. **Effect of Milk or Meat Diet on Secretion of Hydrochloric Acid.**—Cloetta describes the results of experiments on a litter of puppies fed exclusively on milk with a little iron, or exclusively on raw meat. The milk dogs seemed to thrive a little better than the others. They were all tested for hydrochloric acid at regular intervals and the findings were constant, that there was complete absence of the acid in the milk dogs while the others showed constantly about 2.5 per 1000 free hydrochloric acid after a test meal. They were shot when eleven months old and the gastric mucosa carefully examined. No anatomic differences could be detected between the stomachs of the dogs that had never secreted hydrochloric acid and those with copious secretion. The practical results of these experiments are the assumption that milk diet will have a tendency to diminish an excessive secretion of hydrochloric acid in man, but that it is hopeless to expect an anatomic regeneration of the hyperfunctioning mucosa, as the anatomic conditions are the same with or without acid production.

80. **Treatment of Plastic Induration of Corpora Cavernosa Penis.**—Galezewsky was consulted by a patient who complained of pains from an induration in the corpora cavernosa, so severe during erection that he was almost impelled to suicide. He had acquired syphilis in youth and was 47 years old at the time. Specific and local treatment proved ineffectual, and in spite of the danger of further trouble from cicatricial contraction, the lump was removed through a longitudinal incision, and the defect obliterated by lengthwise catgut stitches, over which the skin was sutured with silk. The patient was freed from all his pain and disturbances and the effect has been unimpaired for almost three years. The cause was probably some slight traumatism, as a similar induration started at the point where compression was applied to the organ for twenty-five to thirty minutes during the operation. It soon subsided spontaneously or in consequence of the sitz baths ordered.

81. **Delivery with Narrow Pelvis.**—Krönig compares the results attained at various French and German lying-in hospitals, and shows from the figures that prophylactic version, premature artificial delivery and the high application of the forceps have failed to show as good results as have been obtained without them. Many cases triumphantly reported as successes of premature delivery or prophylactic version might have terminated in spontaneous delivery, as others under exactly similar circumstances proceeded under expectant treatment to a spontaneous termination. The size of the pelvis is not everything—the comparative size of the fetal head must be taken into account. He believes that the best results will be attained when the obstetrician is content to wait and watch the course of events without interference. When expectant treatment has terminated in the absolute conviction that the disproportion between the fetal head and the size of the parts prevents normal delivery, then he should choose the mode of intervention as indicated, bearing in mind that symphysiotomy almost invariably leaves an elastic cicatrix which enables the parts to stretch in future childbirths and thus prevents further trouble from this source. The chief drawback is that the operation does not guarantee a living child as it is merely a preparation for natural delivery, while with Cesarean section the child is extracted at once.

82. **Purgatin.**—Hösslin corroborates the favorable reports on purgatin that have been published from the clinics of Ewald, Stadelmann and Ebstein. He found it a mild purgative which does not act for twenty-four hours or more, but then seems to empty the bowels completely, softening all the scybala. No by-effects were noted in any case in his experience.

83. **Etiologic Relations Between Chorea and Infectious Diseases.**—Koster found in 90 out of 121 cases of chorea minor, that is, 74.3 per cent., that there was a preceding history of some infectious disease or affection or traces of such in the tonsils and heart. Five of the other patients were hysterics and 3 over 35 years of age scarcely belong to the

domain of chorea minor. It dated from a fright in 9 others. These and the others were all of pronounced neuropathic tendency. Chorea is evidently due, he thinks, to an individual predisposition. A slight cause, trauma, fright or mild infectious disease, even a catarrhal fever, follicular tonsillitis, bronchitis or rheumatic affection may induce it in the predisposed. He seldom if ever encountered it in children from well-to-do families.

104. **Contusion of the Kidneys.**—Sarytcheff states that 18 cases of subcutaneous injury of the kidney have been published by Russian surgeons and he has had an experience of 5. One patient fell from a height on an iron fence, striking on his left side, and one was injured in a fight. Both were drunk at the time. A third fell on a wooden fence. They were treated merely symptomatically, with repose, applications of ice, ergot, codein, morphin and Haller's elixir, with clinical recovery and dismissal the seventh to the thirty-sixth day. The fourth patient fell from a platform and was unconscious for two hours. She was a healthy ii-para. The injury to the kidney was so severe in this case that after the soundness of the other kidney had been determined by cryoscopy, the injured organ was partially resected. The fifth patient was also a woman, 27 years of age, and sustained the contusion by falling from a ladder. An operation was indicated, but she refused to permit it and left the hospital in eleven days with still persisting hematuria. The symptoms in all these cases were pain in the region of the injured kidney and hematuria. There was no rigidity of the abdominal wall which has sometimes been observed. He remarks that rising temperature at first does not necessarily mean suppuration in or around the organ. The diagnosis of injury of the kidney was confirmed by the cystoscope. He recommends a prompt exploratory incision as a harmless means of determining the extent of the injury. Progressive anemia in such cases indicates that one or more blood vessels have been injured, and swelling suggests the development of a pseudo-hydronephroma or hematoma. All his patients recovered. He gives a cut of the microscopic findings in the one kidney that was removed. There was no subcutaneous hemorrhage in any of his cases and shock was noted only in two. The hematuria did not cease in one of the cases treated symptomatically until the twenty-seventh day after the injury. He recommends his practice of partial instead of complete nephrectomy, leaving a portion at least until the other kidney has acquired compensating power.

112. **Cause and Treatment of Alveolar Pyorrhea.**—Znamenski gives a number of illustrations of various phases of the anatomic process in alveolar pyorrhea, to sustain his assertion that the lesion in the bone in these cases is essentially an ostitis rareficiens. Different general pathologic processes, constitutional diseases and disorders may lead to atrophy of the alveoli. In mild cases when only a portion of the bone is involved and the marrow is still intact, ordinary hygienic and disinfecting measures suffice, but in the severer cases the bone must be scraped and a general tonic or specific general treatment instituted. He recommends as a prophylactic measure the chewing of the crust of hard bread or similar substances, as a gymnastic exercise for the bones, gums and teeth.

119. **Phrenic Phenomenon, New Symptom in Tetany.**—Solovieff has observed in two patients a hitherto undescribed symptom in tetany. His attention was attracted to it by complaints of palpitation and it was noticed that the lower interspaces on the left side were drawn in rhythmically, corresponding to the heart-beats. Radioscopy revealed that the left half of the diaphragm contracted simultaneously with each heart-beat while the right half was passive and moved only as pulled by the contraction of the left side. The resulting symptoms and slight bruit were observed in a second patient on the third day after admission to the hospital, but they vanished again by the following day. The patients were youths, 16 to 18 years old.

120. **Stab Wounds of the Abdomen.**—Finkelstein proclaims that the prognosis of a simple stab wound of the abdomen is very favorable. In 132 cases in his experience 70.4 per cent. of the patients recovered with no symptoms indicating injury of an internal organ. In Hoxie's experience, 53.2 per cent. of 47 cases, and in Tanzcher's, 59 per cent. of 46 recovered without complications. In Finkelstein's 39 complicated cases the intestines were injured in 15, the liver in 13, stomach in 6, mesentery in 3 and the spleen in one, while in another several organs were injured. When the condition of the internal organs can not be decided by a laparotomy, the prognosis should be guarded, as symptoms of peritonitis may not appear until the fifth to sixth day, especially in case of injury of the stomach. When the diaphragm was injured some viscus was also injured in 25 per cent. of the cases. The danger of consecutive hernia should be averted in such circumstances by suturing the wound if in the left side of the diaphragm. The left half of the liver was involved in 77 per cent. of all cases of injury of this organ. Hemorrhage was copious in 84 per cent., but in 16 per cent. the lesion occurred without causing symptoms. There was no escape of bile after tamponing in 64 per cent. Out of the 13 patients whose liver was injured, 5 died. He considers the tampon the quickest and most reliable means of arresting hemorrhage, but he finds on reviewing the communications of 17 authors on the subject that suturing was found effective in deep and copiously bleeding wounds of any part of the liver. It increases the possibility of suppuration, however, and must be supplemented occasionally by tamponing to arrest escape of bile. In case of injury of the stomach, the first days may elapse with no indications that an internal organ has been injured. When the operation is not undertaken until after the appearance of symptoms of peritonitis, the prognosis is unfavorable. The posterior wall of the stomach was injured in 16 per cent. and should be inspected at every laparotomy done for a stab wound of the abdomen. In 6.6 per cent. of the cases in which the intestines were injured there were no indications of the lesion during the first days. Peritonitis usually developed symptoms in twenty to twenty-four hours. Only one patient recovered out of 7 operated on after the signs of peritonitis were observed, and only 6 out of the total of 14 cases of intestinal complications operated on. The proportion of recoveries after injury of the large intestine was much larger than when the small intestine was involved. Only one recovered out of the 3 with injury of the mesentery. It caused profuse hemorrhage in each case. The general mortality of his 132 cases was 18 per cent., while for the uncomplicated cases it was only 5.3 per cent. and for the complicated, 53.8 per cent. Death was due to shock in 3; in one of these the stomach was wounded and in the others there was no complication. Prompt laparotomy is indicated, without waiting for the development of symptoms. Finkelstein describes a number of his cases with details.

122. **Appendicitis in Women.**—An appendicitis may simulate or mask a salpingitis, etc., or vice versa, but as the indications are the same for each, differentiation before operating is not very important. But during the operation disastrous results may follow if an inflamed appendix or tube is overlooked and left while operating on another lesion. He describes several puzzling cases and states that cases of appendicitis are on record in which the pain was referred to the left side, while salpingitis may occur exclusively on the right side. He gives a cut of an enormously swollen tube on the right side, simulating appendicitis, while the appendix crowded up beyond it was intact. General peritonitis due to appendicitis was invariably fatal in his experience, irrespective of surgical intervention, while a number of cases of general peritonitis originating in the genital organs, terminated favorably. The pain is located higher up, usually, in appendicitis than in salpingitis, and the onset is more sudden and severe. The resulting diffuse peritonitis is naturally more serious.

125. **Suprapubic Lithotomy in Children.**—Tikhoff gives the details of a dozen cases of urinary calculi in children which he operated on. Four were 2 years old, and 4 between 10 and 14. He proclaims that the Razumovski method is peculiarly applicable in these cases. The chief feature of the method is the fastening of the bladder to the anterior abdominal wall.

This not only favors cicatrization but aids in hermetically closing the wound in the bladder. The absence of buried sutures prevents the future development of stones around a suture. The cystopexy enables the wound in the bladder to heal completely in seven or eight days, free from oozing of urine with all its consequences. It shortens the post-operative period even in cases in which the suture was not complete, and it also enables the wound to be opened again if necessary. No special instruments are needed for it. Razumovsky has formulated the indications for this intervention in adults and they apply equally well to children. The only contraindications are an extremely poor general condition and severe nephritis. Tikhoff concludes by reiterating that the Razumovsky method is a most valuable acquisition for the surgical treatment of urinary stone affections in young and old.

129. **Malaria in Turkestan.**—Mark's extensive experience with malaria in various districts of Turkestan showed that the cases of tropical or meridian fever were eight times more frequent in the southern, tropical portions than in the hill country with a temperate climate. He believes that there are three kinds of malarial parasites which form two groups, those which can develop only in a tropical environment and those which grow in a temperate climate, the tertian and quartan. The type of malaria prevalent in a locality therefore depends on the climate of the place. Tuberculosis assumes a more rapid course under the influence of malaria. He reviews the recent literature on the subject of malaria and describes a number of exceptional cases of malaria from his experience with 161 patients.

137. **Operation for Epispadia.**—Four large cuts give a better idea of the operation performed by Muratoff than any verbal description and we refer those interested to the original. The task was to form a male urethra out of the well-developed labia of an apparent female. The patient had always been troubled with incontinence of urine. One of the steps of the operation was to form a flap out of the upper portion of the hymen.

140. **Pathogenesis and Treatment of Eclampsia.**—The Journal has frequently quoted Stroganoff's views in regard to the infectious character of eclampsia, xxxi, p. 1190, and elsewhere. He now presents arguments against the uremic theory and the theory of infection from the fetus, among them the fact that out of 126 cases of eclampsia in his experience in the last five years he has observed 10 cases occurring in the early months of pregnancy in which, after the cessation of the eclamptic seizures, the pregnancy continued to a normal termination. This could scarcely occur if the eclampsia were due to toxins generated by the fetus. Another argument is that the eclampsia which occurs in the first months of pregnancy affords usually the worst prognosis. He has lost only 8 out of the total of 126 cases, and in all but 2 of these fatal cases the eclampsia had developed before the patients were received in the maternity. He concludes with the statement that time has confirmed the efficacy of preventive measures as for any infectious disease, and of his method of treatment with administration of oxygen during the convulsions, controlling them with morphin and chloral, saline infusion and hastening delivery when convulsions do not yield to treatment. (See The Journal, xxxiv, p. 735, and xxxviii, p. 670.)

141. **Acetonuria in Gynecologic Affections.**—Krivoshein does not formulate any absolute conclusions from his researches on this subject as they are not sufficiently extensive. But he calls attention to the fact that fibromatosis evidently induces an acute deviation from normal in the oxidation processes, as established by the constant finding of acetonuria in this affection.

144. **Application to Gynecology of Intrarectal Urethral Plastics.**—Subbotin's method of treating exstrophy of the bladder by constructing a new bladder and urethra, with a sphincter, out of the rectum, was described and illustrated in The Journal of Jan. 18, 1902, p. 211. The permanent results in the two cases reported have been most excellent. Gruzdeff now announces that the operation is also applicable to certain gynecologic affections and describes a case of extensive vesicovaginal fistula with complete destruction of the urethra, which he succeeded in curing by this means. He slightly modified the technic described by Subbotin and commends this new operation to the serious attention of gynecologists as well as of surgeons in general. He describes his case and operation in detail, but without illustrations.

146. **Value of Strychnin in Treatment of Progressive Deafness.**—Berezovski announces that the subcutaneous administration of strychnin practically cured two patients with progressive deafness and annoying subjective sounds in the ears. It also attenuated or completely banished the sounds in 17 out of 22 other cases of various forms of aural affections. He remarks that he has never known in his own experience nor heard from others nor been able to find in literature a single instance of complete cure of progressive deafness by any means. Consequently he believes that the cure of the two cases he reports, even if they were only 2 out of 2000 instead of being 2 out of 2, should suggest further trials in this line. He has found strychnin useful also in amblyopia and other affections of the eyes. He injects the strychnin in the usual hypodermic dose. Other methods of administration proved ineffectual.

New Patents.

Patents of interest to physicians, etc., Aug. 19 and 26, 1902.

707089. Corn pad. Ira Duckworth, Fort Smith, Ark.

707508. Electric roller for massage and therapeutic purposes. John W. Gibbs, New York.

707423. Obtaining albuminous substances. Adolf Jolles, Vienna, Austria-Hungary.

707438. Medical electrode. George G. Marshall, Wallingford, Vt.

707445. Inhaler. John H. McCulloch, Newville, Pa.

707258. Leg-improver. Harry A. Rhonemus, Springfield, Ohio.

707282. Nebulizer. Charles Truax, Chicago.

707187. Rotary bake-oven. Frank H. Van Houten, Fishkill-on-the-Hudson, N. Y.

707562. Electrotherapeutic battery. Thomas J. Dunn, Jersey City, N. J.

707619. Hernial truss. Joseph H. McKague, Columbus Heights, Minn.

707623. Elastic anesthetic apparatus. Herman Nieriker, Zurich, Switzerland.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A Text-Book of Medicine. Begun by the Late Charles Hilton Fagge, M.D., F.R.C.P., Sometime Physician to Guy's Hospital, Completed After His Death and Since Revised or Rewritten by Philip Henry Pye-Smith, M.D., F.R.S., Fellow of the Royal College of Physicians. Fourth Edition in Two Volumes. Vol. II. Cloth. Pp. 1050. Price, $6.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

A Treatise on the Diseases of the Throat, Nose and the Associated Affections of the Ear. By Charles P. Grayson, M.D., Lecturer on and Instructor in Laryngology in the Medical Department, University of Pennsylvania. In One Octavo Volume of 540 Pages, with 129 Engravings, and 8 Colored Plates. Cloth $3.50 net. Lea Brothers & Co.: Philadelphia and New York. 1902.

Psychopathological Researches. Studies in Mental Dissociation with Text Figures and Ten Plates. By Boris Sidis, M.A., Ph.D., Director of the Psychopathological Laboratory. Published under the Auspices of the Trustees of the Psychopathic Hospital, Department of the New York Infirmary for Women and Children. Cloth. Pp. 329. Price, $3.00 net. New York: G. E. Stechert. 1902.

Manual of Bacteriology. Clinical and Applied. With an Appendix on Bacterial Remedies, etc. By Richard T. Hewlett, M.D., M.R.C.P., D.P.H. (Lond), Professor of General Pathology and Bacteriology, King's College, London. Second Edition. Cloth. Pp. 533. Price, $4.00. Philadelphia: P. Blakiston's Son & Co. 1902.

Jahresbericht über die Fortschritte in der Lehre von den Pathogen Mikroorganismen unfassend Bacterien, Pilze und Protozoën unter Mitwirkung von Fachgenossen bearbeiter von Dr. med. P. von Baumgarten un Dr. med. F. Tangl. Sechzehnter Jahrgang 1900. Paper. Pp. 812. Leipzig: Verlag von S. Hirzel. 1902.

Transactions of the Medical Association of the State of Missouri At Its Forty-Fifth Annual Session, held at St. Joseph, Mo., May 20, 21 and 22; 1902. Cloth. Pp. 269. St. Louis: Nixon-Jones Printing Co. 1902.

Transactions of the Thirty-second Annual Session of the Medical Society of Virginia, held in Lynchburg, Va., Nov. 5-7, 1901. Cloth. Pp. 330. Richmond, Va.: Williams Printing Co. 1902.

Transactions of the Arkansas Medical Society. Twenty-seventh Annual Session, held at Little Rock, Ark., May 13, 14 and 15, 1902. Paper. Pp. 201. Little Rock, Ark.: Tunnah & Pittard. 1902.

Die Roentgenstrahlen im Dienste der Chirurgie. Von Dr. Carl Beck, Professor der Chirurgie, New York. Book I and II. Cloth. Pp. 138. Verlagsbuchhandlung Seitz & Schauer. 1902.

Transactions of the Florida Medical Association. For the Year 1902. Held at Tampa, Fla., April 9, 10 and 11, 1902. Paper. Pp. 127. Jacksonville, Fla.: Garrett Printing Co. 1902.

Dr. Prassitele Piccinini. Farmacoterapia con formulario. Un volume di pag. viii-382, elegantemente legato in tela. Ulrico Hoepli. Milano. (L. 3,50.)

Proceedings of the Orleans Parish Medical Society. Issued June, July 1, 1902. Paper. Pp. 17 and 18, respectively. Published Monthly by the Society.

Army List and Directory. Officers of the Army of the United States. Aug. 20, 1902. Paper. Pp. 72. Washington: Government Printing Office.

Transactions of the Sixty-ninth Annual Session of the Medical Society of the State of Tennessee. Memphis, 1902. Cloth. Pp. 306.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Aug. 28 to Sept. 3, 1902, inclusive:

W. Edson Apple, captain, asst.-surgeon, U. S. Vols., honorably discharged from the service of the United States, to take effect Oct. 10, 1902, his services being no longer required.

Alexander P. Bacon, contract dental surgeon, U. S. A., now at Fort Clark, Tex., is relieved from duty in the Department of Texas and will proceed to Fort Yates, N. D., for temporary duty at that post.

William B. Block, captain and asst.-surgeon, U. S. Vols., as Captain Apple, above.

Henry L. Brown, contract surgeon, U. S. A., member of a board at Fort Sheridan, Ill., to examine candidates properly ordered before it as to their fitness for appointment as chaplains in the U. S. A.

Frederick J. Combe, major and surgeon, U. S. Vols., as Captain Apple, above.

Charles M. Drake, major and surgeon, U. S. Vols., now on leave of absence at Atlanta, Ga., as Captain Apple, above.

Vernon K. Earthman, major and surgeon, U. S. Vols., now on leave of absence at Murfreesboro, Tenn., as Captain Apple, above.

James D. Glennan, major and surgeon, U. S. A., on being relieved from duty at the U. S. Military Academy, West Point, N. Y., will proceed to Fort Douglas, Utah, to relieve Major Henry F. Hoyt, surgeon, Vols., U. S. A.

William C. Gorgas, major and surgeon, U. S. A., is relieved from duty at Havana, Cuba, to take effect Sept. 30, 1902, and will then repair to Washington, D. C., and report to the Surgeon-General for instructions.

Henry F. Hoyt, major and surgeon, U. S. Vols., as Major Combe, above.

Francis J. Ives, major and surgeon, U. S. A., as Surgeon Brown, above.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a board at San Francisco, to examine officers of the Army for promotion.

Damaso T. Laine, major and surgeon, U. S. Vols., as Major Combe, above.

Louis M. Maus, lieut.-col., deputy surgeon-general, U. S. A., on his arrival at San Francisco, will proceed to West Point, N. Y., for duty at the U. S. Military Academy, to relieve Major James D. Glennan, surgeon, U. S. A.

Donald P. McCord, captain, asst.-surgeon, U. S. Vols., honorably discharged from the service of the United States, to take effect Sept. 30, 1902; leave of absence granted until that date.

T. C. McSwain, contract surgeon, U. S. A., leave of absence granted to include Sept. 30, 1902.

Charles B. Mittelstaedt, contract surgeon, U. S. A., detailed a member of an examining board at Fort Ethan Allen, Vt., vice Lieutenant Charles F. Morse, asst.-surgeon, U. S. A., relieved.

George J. Newgarden, captain, asst.-surgeon, U. S. A., relieved from further treatment at the Army and Navy General Hospital, Hot Springs, Ark., and will go to his proper station at Fort Mason, Cal.

William F. de Niederman, major and surgeon, U. S. Vols., as Major Combe, above.

George L. Painter, captain, asst.-surgeon, U. S. Vols., as Captain Apple, above.

Harper Peddicord, contract surgeon, U. S. A., now at Columbus Barracks, Ohio, will report for duty at that post.

Thomas L. Rhoades, lieutenant and asst.-surgeon, U. S. A., as Major Kilbourne, above.

D. M. Roberts, contract surgeon, U. S. A., leave of absence from the Department of Texas extended one month.

Charles A. Sturtevant, contract surgeon, U. S. A., is relieved from duty at Fort Slocum, N. Y., and assigned to duty at Madison Barracks, N. Y.

Ralph L. Taylor, contract surgeon, U. S. A., former orders which directed him to repair to Washington, D. C., amended so as to direct him to report to the commanding general, Department of California, for assignment to duty as transport surgeon on the transport *Warren*, to relieve Captain Donald McCord, asst.-surgeon, Vols., U. S. A.

Edwin P. Tignor, contract dental surgeon, U. S. A., leave of absence from the Department of the Missouri extended ten days.

William L. Whittington, major and surgeon, U. S. Vols., now at St. Joseph, Mo., as Captain Apple, above.

Robert E. Williams, captain, asst.-surgeon, U. S. Vols., as Captain Apple, above.

The officers of Volunteers, U. S. A., honorably discharged as above ordered are directed to proceed to their homes on receipt by them of their orders.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy, week ending Sept. 6, 1902.

Surgeon N. H. Drake, detached from the Mare Island Navy Yard and ordered to the *Solace*.

Surgeon W. R. DuBose, detached from the *Solace*, on reporting of relief, and ordered home and to wait orders.

Asst.-Surgeon W. H. Ulsh, ordered to the Washington Navy Yard for examination, and thence home and to wait orders.

Medical Director R. A. Marmion, detached from duty as president of the medical examining boards, Washington, D. C., and ordered to duty as president of the naval medical examining board and to duty in charge of the Naval Museum of Hygiene and Medical School, Washington, D. C.

Medical Director G. P. Bradley, on completion of duty as a member of the board for the examination of midshipmen, detached from the Naval Museum of Hygiene, Washington, D. C., and ordered to duty as a member of the medical examining board and naval retiring board, Washington, D. C.

Surgeon R. M. Kennedy, detached from the *Franklin*, and ordered to the torpedo station, Newport, R. I.

Asst.-Surgeon J. J. Snyder, detached from the torpedo station, Newport, R. I., on reporting of relief, and ordered to the naval hospital, Philadelphia.

Surgeon E. O. Huntington, order of August 15, modified; detached from the naval hospital, New York, and ordered home in obedience to order referred to.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Sept. 6, 1902:

SMALLPOX—UNITED STATES.

California: Los Angeles, Aug. 16-23, 1 case; Sacramento, Aug. 16-23, 2 cases.

Colorado: Denver, Aug. 16-23, 2 cases.

Illinois: Belleville, Aug. 23-30, 1 case.

Indiana: Indianapolis, Aug. 23-30, 3 cases.

Iowa: Ottumwa, Aug. 2-30, 2 cases.

Kansas: Wichita, Aug. 23-30, 3 cases.

Maine: Portland, Aug. 23-30, 1 case.

Massachusetts: Boston, Aug. 23-30, 5 cases; Brockton, Aug. 23-30, 3 cases; Lawrence, Aug 23-30, 1 death; Somerville, Aug. 23-30, 2 cases.

Missouri: St. Joseph, Aug 23-30, 9 cases; St. Louis, Aug. 24-31, 12 cases.

Montana: Helena, Aug. 1-31, 1 case.

Nebraska: Omaha, Aug. 23-30, 2 cases.

New Hampshire: Manchester, Aug. 23-30, 1 case.

New Jersey: Camden, Aug. 23-30, 7 cases; Newark, Aug. 23-30, 4 cases, 1 death.

New York: New York, Aug. 23-30, 6 cases, 1 death.

Ohio: Cincinnati, Aug. 22-29, 2 cases; Cleveland, Aug. 23-30, 76 cases, 6 deaths; Hamilton, Aug. 23-30, 3 cases; Middletown, July 12-Aug. 9, 11 cases.

Pennsylvania: Erie, Aug. 23-30, 1 case; Johnstown, Aug 23-30, 12 cases, 1 death; McKeesport, Aug. 23-30, 2 cases, 2 deaths; Philadelphia, Aug. 23-30, 4 cases, 1 death; Pittsburg, Aug. 23-30, 12 cases, 5 deaths.

Wisconsin: Green Bay, Aug. 23-31, 3 cases; Janesville, Aug. 23-30, 1 case; Milwaukee, Aug. 23-30, 1 case.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, June 1-30, 3 deaths.

Austria: Prague, Aug. 2-16, 1 case; Trieste, Aug. 8-16, 1 case.

Barbados: *July 13-Aug. 12, 47 cases.*

China: Hong Kong, July 12-19, 1 death.

France: Paris, Aug. 2-16, 2 deaths.

Great Britain: Dundee, Aug. 8-16, 1 case; Glasgow, Aug. 16-23, 1 case; London, Aug. 8-16, 24 cases, 5 deaths.

India: Bombay, July 29-Aug. 5, 5 cases, 5 deaths.

Italy: Palermo, Aug. 2-9, 5 cases, 2 deaths.

Netherlands: Rotterdam, Aug. 16-23, 1 case.

Russia: Moscow, Aug. 2-9, 1 case; Odessa, Aug. 8-16, 2 cases, 1 death; St. Petersburg, Aug. 2-9, 4 cases.

Spain: Corunna, Aug. 8-16, 20 deaths.

Uruguay: Montevideo, July 9-23, 43 cases, 2 deaths.

YELLOW FEVER.

Columbia: Panama, Aug. 18-25, 1 case.

Costa Rica: Port Limon, Aug. 7-14, 1 case, 1 death.

Ecuador: Guayaquil, Aug. 8-16, 5 cases, 2 deaths—imported.

Mexico: Coatzacoalcos, Aug. 16-23, 5 cases, 1 death; Vera Cruz, Aug. 16-30, 33 cases, 4 deaths.

PLAGUE.

China: Hong Kong, July 12-19, 21 cases, 20 deaths.

Egypt: Alexandria, Apr. 14-Aug. 13, 72 cases, 35 deaths.

India: Bombay, July 29-Aug. 5, 32 deaths; Calcutta, July 26-Aug. 2, 11 deaths; Karachi, July 27-Aug. 3, 12 cases, 5 deaths.

Madagascar: Tamatave, July 6-22, 18 cases, 14 deaths.

CHOLERA—INSULAR.

Philippine Islands: Cebu, July 9-20, 90 cases, 52 deaths.

CHOLERA—FOREIGN.

China: Hong Kong, July 12-19, 6 cases, 5 deaths.

Egypt: Alexandria, Aug. 5-13, 8 cases, 7 deaths; Cairo, July 22-Aug. 13, 556 cases, 490 deaths; Assiout Province, including Moucha, July 15-Aug. 13, 536 cases, 434 deaths; Behera Province, Aug. 12-13, 13 cases, 4 deaths; Beni Souef, Aug. 11, 1 case; Charkieh Province, July 12-13, 6 cases, 5 deaths; Galloubieh Province, Aug. 6-13, 20 cases, 11 deaths; *Gharbieh Province*, Aug. 13, 1 death; Guizeh Province, July 25-Aug. 13, 159 cases, 93 deaths; Menoufieh Province, Aug. 9-13, 6 cases, 6 deaths; Minieh Province, Aug. 9-13, 24 cases, 13 deaths.

India: Bombay, July 29-Aug. 5, 1 death; Calcutta, July 26-Aug. 2, 22 deaths; Karachi, July 27-Aug. 3, 21 cases, 21 deaths.

Japan: Osaka, and Hiogo, July 26-Aug. 9, 2 cases, 1 death.

Korea: Chenampo, Aug. 21, severe; North Korea, Aug. 21, severe.

Vol. XXXIX. CHICAGO, ILLINOIS, SEPTEMBER 27, 1902. No. 13.

Address.

HOSPITALS FOR THE NEUROPATHIC AND PSYCHOPATHIC.*

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON NERVOUS AND MENTAL DISEASES, AT THE FIFTY-THIRD ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, AT SARATOGA SPRINGS, N. Y., JUNE 10-13, 1902.

RICHARD DEWEY, A.M., M.D.
WAUWATOSA, WIS.

The development of institutions for nervous and mental maladies forms no exception to the rule that increased complexity (and perplexity) follows the process of finer adaptation to the requirements of advancing medical science and social evolution. Change and growth are so rapid that the conservatism which necessarily characterizes all institutions, keeps them lagging behind in the advances of the day in the art and science of both neurology and psychiatry.

It is not necessary to prove in this audience that there is in our own time a very great increase of nervous diseases, both in variety of forms and in the number of sufferers. The same is also true of mental diseases, and hence the subject of provision for patients of this class is a pressing one in all our communities. In this paper I seek to consider only hospital treatment largely for recent and curable cases. Thus far it has been principally only where mental integrity was impaired that separate provision has been made; as in the separate institutions for insane, the feeble-minded and the epileptic, and even these classes were, in the first instance, separated from the community only because they were a menace or an annoyance in the commonwealth, and not for their own welfare or for curative treatment. Considering for a moment the case of the psychopathic, the mere utterance of a few words will illustrate to you the history of provision for mental maladies. The terms "demoniac," "lunatic," "insane" and "psychopathic" correspond to the "jail, "asylum," the "hospital," and now, I may add (to coin a word), the "psychiatrium," or the "psychopathic hospital," which is growing up before our eyes. The word "Bethlem" is a history in itself. The "Bethlem Royal Hospital" in London began to receive the insane in the fifteenth century, and from that time until the beginning of the nineteenth it was a place of horrors and suffering inconceivable. Until a comparatively recent time it was visited by the public as a show or "menagerie," and, like the latter, was subject to a "stirring up of the animals" in their cages and a rattling of their chains for the amusement of the crowd. Even to-day something of this idea survives in the unenlightened mind. Though the day of the cell and manacle has passed by, and any physical restraint is now rather the exception than the rule, yet even fairly intelligent persons are heard to ask, when visiting an asylum, that they may be shown those who are, as they imagine, "chained" or caged up in their cells, and they sometimes seem incredulous when told there are no such. The difference between "Bethlehem," our Lord's birthplace, and "bedlam," the dwelling, or rather prison, of the "bedlamites," is no greater than that between the ideas of the masses and those which we, as specialists in the healing art, have learned to entertain.

Along with the most benevolent intentions, the masses, even of the medical profession, have but the faintest notion of what is required for the care of nervous or mental disease, and these latter for the very good reason that no adequate study or teaching of these maladies has obtained, or perhaps was possible until within recent years, and we have a work to do which is primarily educational, both for the public and for the masses, even of our own profession.

Taking now the matter of provision for the mental maladies as illustrating the process of development, it may be truly said, that it is only within 20 or 30 years that any conception has existed of the varying requirements of this class. Twenty years ago I published a paper in the *American Journal of Insanity* on "Differentiation in Institutions for the Insane," in which I urged that the epileptic, the criminal and the alcoholic cases required separate provision and removal from the general insane hospitals, so that the curable cases could be better cared for and the work better organized. At that time a single institution existed in our country for the criminal insane; there was none for the epileptic then, nor for many years after, and the cases of alcoholic and drug inebriety could only be cared for by being committed as insane to some public asylum (except the handful of such cases as could command private care), and when we consider, even to-day, how true it still is that these classes are unprovided for, we see how much there is still to be accomplished. Since then, and within very recent years, there has grown up a strong interest in and demand for special and separate care for the acute and curable insane, thanks to the efforts of enthusiasts for humanity and progress in the medico-psychologic and the neurologic associations of our own and other countries. Criminal asylums have been erected in many states, epileptic colonies and hospitals are rapidly springing up, a beginning has been made in the public care of the inebriate. The provision of convalescent homes for nervous and mental maladies has also been eloquently urged and brought to the attention of the profession and the public. Great improvements have been made in plan and construction of instiuttonsi by segregation in separate, suitable buildings admitting of better classification. Detention hospitals have been provided in most of the larger cities where acute cases could receive prompt, suitable and often beneficial treatment, pending further disposition of their cases. But, however much is done, we see still more to do and the constant necessity of better adaptation of means to ends.

Now, considering separate provision for purely nervous diseases, we see, on looking over the ground, that anything of the kind has scarcely an existence, if we except the private sanitariums, hospitals and nervine homes that have been provided for the well-to-do, and one of the saddest pages in contemporary medical history is that which tells of the great number of patients who are poor or slenderly provided with this world's goods, for whom there is no care or treatment available; "who have not where to lay their head"; who can not recover at home and will not go to a public asylum or hospital, and cannot afford the expense of private care.

Taking these private institutions and examining into the forms of nervous and mental disease there represented, we see that the neuropathic and the psychopathic are commingled in all of them in a manner that goes to show one of two things—either the two classes belong together to a great extent or else their separate needs are largely ignored. The consideration of the neuroses as distinguished from psychoses shows that the former have largely a psychopathic element in them.

Take hysteria, one of the most frequent. We are at once confronted with the fact that this neurosis is also a psychosis. The mental functions are almost universally affected in hysteria, and, in fact, many writers classify hysteria among the mental diseases. Next, neurasthenia presents itself, and we need only ask ourselves as to the mental state found in neurasthenia to recognize that a large number of cases exhibit decided mental aberration—melancholia is a most common accompaniment of neurasthenia. "Nervous prostration" is often only a polite misnomer for insanity. Another large class of neurasthenics in whom the phobias and obsessions are found, forms really a group of cases of mild delusional insanity. So-called hypochondria is often a mild insanity. Harmless paranoiacs are generally classed among nervous invalids and not with the insane. If they are well-to-do they go to a private sanitarium; if indigent, to the public asylum. Chorea is very generally accompanied by mental changes, as has been recently pointed out by Moyer.

The large class of persons addicted to drugs and alcohol forms an important group, and here we have patients in whom very often, in the practical sense, insanity exists when the culmination of the drug or alcohol habit renders medical care and treatment necessary.

Take now the extensive class of organic diseases affecting the brain or spine, or periphery, in which we do not ordinarily say the patient is insane—hemiplegia, paraplegia, brain tumors, neuritis. It is indisputable that in a large majority of these the mind is disordered and functional or organic insanity exists.

The toxemias, which produce neuroses, syphilis, metallic poisoning, uremic poisoning, the neural complications of heart and kidney disease and arterial disease are accompanied by psychic complications almost invariably. Again, autotoxic diseases from deranged metabolism affecting the nervous system very generally affect the mind.

Finally, consider epilepsy. So far as its objective effects and symptoms are concerned they consist largely in insanity. Most of such individuals, whenever they are sick at all, are sick mentally, but are practically sane in the interval.

The treatment of very many of these neurotic cases needs to be the same as of the psychoses, and a hospital suitable for the one would be suitable for the other. On the other hand, it seems to me that if the attempt were made to create a purely neuropathic hospital and admit to it only those who were strictly mentally sound, the positions of the physicians and nurses would be sinecures. At the same time, if all who were admitted sought the benefits of the establishment because it was supposed that insane cases were not there received, it would be a growing enterprise and require to rapidly increase its capacity, so great is the prejudice aroused by the name "insanity," though the same condition under the name of "nervousness" would arouse no apprehension.

And here I may be pardoned for a few words as to the conception of insanity generally held. What is insanity? I do not ask this question with a view of adding to the numerous remarkable definitions already published. I simply inquire what the word insanity means to the general mind, both lay and professional, and I answer; that while you and I know that the hysteric, the neurasthenic, the hemiplegic, the toxic and many other cases are insane in the sense that they are mentally diseased and psychopathic, they are not insane in the sense in which the general public, or even the medical profession at large, understands insanity.

Insanity to these means a wild, hallucinatory state; it means noise, violence, suicide, homicide, destructiveness, untidiness—everything that is repellant, everything that is irrational. While at the same time it is a fact that a third of the population of any institution for the insane are persons quite free from these characteristics and who would be suitable inmates of any hospital or nervine home, so far as their appearance, conduct or demeanor go, on the other hand, the delirium of fever or toxis, the harmless fancies of hysteria, the states marked by obsessions and phobias, and the melancholia of the neurasthenic and the hypochondriac, and the emotional weakness of the hemiplegic, are not insanity to the average mind. Nevertheless, these are in their essence to the neuropathologist the same as "mania," "melancholia" and "dementia," and the various forms of universally recognized lunacy. We know that there are those among the insane who are far more rational than others, who are simply classed as "neurotic," and *vice versa.*

This word insanity I devoutly believe is a source of unending confusion and error, and it would be well if it could become obsolete like its predecessor, "lunacy." Insanity means something entirely different to different people who use it. It is unforunate in its etymology and in the fact that more than any other word in common use it is understood so diversely by diverse persons. Its derivation is the latin *sanus,* which means healthy. *Insanus,* or "insane," means etymologically nothing more than "unhealthy." Further, its technical meaning is absolutely different from its meaning in general acceptance.

When a mother, whose gentle daughter has hysterical paralysis, or one whose gifted son is a harmless paranoiac, or a wife whose hemiplegic husband, still brilliant but blurred and emotional, asks: "Is he (or she) insane?" I answer, "No," with the mental reservation, "not as you or the world understands insanity," or I say, "It is a mild psychosis." Fine susceptibilities are not wounded by the word "psychosis." Again, the most palpable case of insanity, one which would be admitted as such by all the rest of the world, is not recognized as such by those nearest and dearest to the patient. The late Dr. Worcester, that keen observer, relates, in one of his observations, how a relative of a patient with most pronounced insanity, when the various convincing evidences were recounted, replied, "I know his mind is not right, but is he insane?" All this is a digression, but helps to illustrate the difficulty of separating the neuropathic and the psychopathic, and of reaching an agreement as to what insanity means and as to who is insane. And another illustration of the way in which insanity means one thing to the medical man and another to the world at large is found in the legal cases where insanity enters in as a question. The vagaries of courts and juries in criminal trials where the plea is insanity are only too familiar. The palpably insane are constantly punished as responsible and the sane criminal often escapes by means of the "insanity dodge." A recent striking illustration is given by Dr. Thayer, in his account of five palpably insane and irresponsible persons found guilty of murder in Maine in recent years and punished like fully responsible persons.

The repugnance to insanity grows in part out of the lingering prejudice surviving from the dark ages, when it was regarded as possession by the devil, and hence a disgrace to all concerned. It is also in other cases felt to be a disgrace because it is supposed to grow out of evil habits, or does, in reality, spring from such habits; but pneumonia, rheumatism, paralysis, Bright's disease, heart disease, which grow out of evil habits precisely as much, are not felt to be a disgrace. The fact of heredity in the general mind also increases the disgrace of insanity, and yet other diseases equally hereditary and equally disgraceful—that is, not at all—like arterio-sclerosis, consumption, gout, are not thought disgraceful and may even be pointed to with pride. Conditions precisely the same as those of insanity exist in other diseases, but are regarded in a wholly different manner. Fevers, surgical operations and the like, occur where the patient is as repulsive and as hard to care for as any insane case, and as disordered mentally, but these are looked upon only with commiseration and sympathy. Repulsive and helpless states growing out of delirium of fever, filthy and offensive conditions occurring in surgical or gynecologic states arouse no horror. The helpless victim of senile dementia need not be considered more repugnant than the swaddled infant. and yet is very differently regarded. Even violent and destructive acts growing out of crime, homicide or suicide, from unrequited affection or violent passion, are thought to be interesting and to have a certain sentimental attractiveness; while the same thing precisely supposed to spring from insanity is repellant to the last degree. This is largely due, as above stated, to the survival from earlier times of the feeling of disgrace attending insanity as a diabolical infliction or a punishment from heaven for exceptional guilt, when it is, in fact, only a disease like any other, differing solely in the fact that it invades brain tissue.

All of the above seems to me to be an argument for the disuse of the word "insanity," and for substituting the more accurate term "psychosis," as is generally done by continental writers, and I firmly believe we shall see a gradual but complete change in this respect.

Returning now to the question of neuropathic and psychopathic hospitals, I would say that as the matter presents itself to my mind, it is not by attempting to erect absolutely separate institutions and dividing, so to speak, the "sheep from the goats" (i. e., all the insane from all who are not so) that the best success may be attained. Such a division is in practice impossible. A hard and fast line cannot be drawn. Persons truly insane, as we understand the word, will always be euphemistically classed as "neuropathic" so long as the term "insanity" is in use, and others who are only neuropathic will be found among the insane as a result of chance, or choice, or necessity. In the public hospitals for insane, although the law erects a barrier and all who enter must be legally declared insane, we find the hysterical, the neurasthenic, the "habit" cases, the paralytic, the epileptic and scores of patients who are not so insane as the paranoiacs, melancholiacs, the paretics and the maniacs, who are numerous in our sanitariums and general hospitals.

There are certain exceptional cases of psychosis, or neurosis, which are harmful to others or for their own welfare, ought to be separated from association with fellow invalids—some temporarily, some permanently. They need special and segregated care, whether neuropathic or psychopathic. Such are all noisy, violent, destructive patients; also such as have an injurious moral influence; such as are repulsive in conduct or appearance. Some individuals of these classes are insane, some are primarily neuropathic and psychopathic at once, and one problem connected with their care is the fact that the objectionable conditions are often fleeting or paroxysmal and require changes of environment accordingly; so that their care is not suitably disposed of by simple incarceration, but requires changes in surroundings and treatment.

It has been taken for granted that association of nervous people with one another was necessarily injurious, and still more, that association with the insane would be disastrous. This is true if we take insanity in its popular meaning, but experience shows practically helpful and beneficial association daily going on, both in the wards of the insane hospital and the precincts of the neuropathic hospital or sanitarium. Even the administering of the rest cure has been claimed to require a private house other than the patient's home for best results, but that part of it carried on with the patient in room and bed would seem to be as well provided for in any well-arranged sanitarium or hospital as in a private house, and it is even possible, and in some cases certain, that the continuation of the treatment after the patient is up, may be more helpful for the associations and the social contact of other patients, provided these are suitably regulated. It is to be wished that more information were available on this point. A comparative study of cases of neurasthenia treated in institutions and in private houses would be valuable, particularly if embracing a long term of years and showing the subsequent history of each case.

As the matter presents itself to my mind, a public neuropathic or psychopathic hospital can be so arranged as to give suitable environment and association (or isolation where required) to the vast majority of both classes, without prejudice to either. I am now speaking only of public provision and discussing essentials and not the preferences or luxuries in which persons of abundant means can indulge.

The psychopathic hospital should be situated in the country, convenient to a good-sized city. In this view I differ from those who advocate a location in the city. Of course. rest treatment and care in bed are equally well in the city, but there is scarcely a psychopathic case able to be out of bed which will not be better for access to lawn and park and for the quiet of the country and for a place to go other than the city street. Of course, all details of sanitary location and construction are taken for granted. The territory should be ample, not less than an acre for each patient accommodated, so that agriculture could be carried on, and the grounds should be attractive. The capacity might vary from 50 to 150. There should be from four to eight buildings for classifying patients. It might be an independent institution or an annex to a larger hospital; the former being the preferable arrangement. One of the buildings should be so widely separated from the others and so arranged internally that the turbulent, noisy and destructive cases or stadia of insanity or delirium could there be cared for without disturbance or annoyance to those in other buildings. This latter building should be surrounded by trees and hedge-rows and have access to a thickly wooded grove. The internal arrangements should be such that patients who were temporarily noisy, violent and destructive would not annoy their neighbors. Where it were possible to have an additional building specially arranged for three to eight turbulent patients of each sex this would be an advantage. Even if these latter were not absolutely separated in another building, such patients could be well cared for without disturbing others, in specially constructed rooms with thick walls, lined with canvas padding, removable for renovation, with separate and specially arranged bathroom and plumbing and with double doors and windows opening on an inner court, and in which thorough ventilation could be secured by suitably located and protected electric fans.

It may be said that all of this turbulent, violent and noisy class should be in an absolutely separated institution, and such an arrangement would have its advantages. It would have, also, its disadvantage, that these violent conditions are often temporary, passing away in hours or days, and when they were over, a transfer would be necessary, and sometimes frequent transfers which would be much more difficult in case it were necessary to go back and forth to another and separate establishment. The epileptic, the periodic maniac, the alcoholic, the violent hysteric, and many nervous invalids not insane as ordinarily understood, would need such accommodation temporarily, hence I advocate the separate or turbulent ward as a part of the psychopathic hospital, knowing it is capable of being arranged so as to be no disadvantage to the other departments, and would be as useful for certain of the neuropathic as for the other class of cases.

I will not speak of the ordinary conveniences and well-known provisions required for nervous and mental cases, such as means of recreation and employment. means of hydrotherapeutic and electric treatment, a well-equipped laboratory, etc., or of a competent, adequate and skillfull medical and nursing staff. Each 25 patients of this class would well employ the energies of an enthusiastic and well-qualified physician, and to every five patients there should be, if possible, an average of one nurse. Some patients, of course, require one, or even two, constant nurses, others are able to do a good deal for themselves.

The other buildings comprising the psychopathic and neuropathic hospital need to be arranged only like any pleasant, comfortable dwelling. Twelve to thirty patients should be the limit in any one building. Some of the buildings should have only one sex; others both sexes in separate wings or floors. One building should be for those needing quiet and solitude. One for those who need sociability, music, games, etc. Congeniality and compatibility should be studied most sedulously, both of patients and nurses. I think one building with means of pleasant but complete isolation should be provided for those who constantly talk about and dwell upon their symptoms or vagaries or are mischievous and annoying to their fellow patients, thereby educating them in self-control and effecting a double benefit.

There is one important consideration in the organization of such an institution which relates to the question of commitment or manner of admission. If the psychopathic hospital, or "psychiatrium," were a public or a state institution, a large part of the neuropathic and most of the psychopathic might go voluntarily, as to any hospital, or in the same manner as to the public sanatoria for the tuberculous, or eye and ear diseases. Voluntary committment should be universally provided for, as is now done by statute in many states. In any case, where the patient's mental condition rendered action necessary irrespective of his will or perhaps in opposition to his wishes, or in cases where involuntary detention might become necessary in the patient's best interest during a state of delirium or irresponsibility, strict safeguards would be necessary to prevent any interference with personal liberty. A law establishing a psychopathic hospital might provide for "close" and "open" wards, and require a legal determination of the mental state, and an order of court for all persons received in the "close" ward or building, and, of course, all such institutions should be subject to visit and inspection systematically by the charity or insanity commissioners. A systematic inspection by sworn medical officers of the state who had expert knowledge of mental diseases might cover this ground. Of course, some difficulties would grow out of having persons, both psychopathic and mentally more or less normal, cared for in one establishment, but none which might not be met by well-considered provisions of the law. Heretofore all persons in the eye of the law regarded as insane have been supposed to be separated from other invalids, but the "eye of the law" has often been blind or affected with strabismus. Everyone familiar with the situation knows that taking institutions for so-called nervous troubles on one side and institutions for the insane on the other, there is in both a heterogeneous association of persons, both sane and insane, according to the point of view. The patients find themselves in one class or the other as a result of a thousand circumstances or chances; their financial circumstances, their own or their relative's willingness or unwillingness to have the official brand of insanity affixed, the emergencies arising from their condition. etc. In general, however, it may be said that of two persons exactly alike in condition, one well-to-do and the other poor, the former would escape a legal commitment and go to a private hospital or sanitarium, while the poor person would be subjected to judicial proceedings and placed in the asylum for the insane—a fact which, considering the superstition and prejudice existing in the public mind, would be a misfortune and a hindrance in the ordinary relations of life in a business and social way, and, although insanity by any other name is just as painful a circumstance, yet it would mean something less serious or detrimental to have gone to the "psychiatrium,' or even to have entered the "close" wards of such an establishment as is here in mind.

Regarding the nurses and attendants for the psychopathic hospital, it may be said that they should be trained or undergraduate nurses, and the standard of care should be such as the nearest and dearest friends of the patient would approve of and give if they were by the patient's side, provided, however, that such nearest and dearest ones were possessed of the wisdom and the harmlessness the scripture tells us of. Here, however, is a source of difficulty. We know but too well that friends and members of the families of those who are nervous and insane are often not judicious and are themselves apt to be unwise and mistaken in their views as to what is best for the welfare of the patient. Out of this fact grows the ancient superstition that friends and members of the family should always be separated from the psychopathic and often from the neuropathic patient. This also accounts for the opinion of attendants and physicians often expressed that the visits of friends do harm. The visits occasionally may be harmful, but there is a strong prejudice also in the minds of attendants and physicians on this subject. If a patient, who is subject continually to violent paroxysms, is visited by a friend and a paroxysm occurs after the visit. it is apt to be attributed to the visit. Sometimes it would have occurred irrespective of visits of friends; again the friends and relatives, lacking all thorough or trained knowledge of what is needful, are apt to form erroneous opinions, and trouble and inconvenience, and sometimes harm to the patient, grows out of this fact. The only remedy, however, is greater freedom and a gradual process of education of the laity. Certainly exclusion and a repellant attitude toward friends leads only to doubt and suspicion and defeats its own object.

Regarding the expense of construction of such hospitals, it is to be recognized that they would be somewhat more elaborate and expensive than the average public institution for the insane, but probably no more so than the average general hospital. It would probably cost about $1,000 per capita to erect them suitably, exclusive of the ground required.

I will endeavor to summarize my remarks by the following statements:

1. It is evident that there is great need of special hospitals where the neuropathic and psychopathic can receive treatment with the aid of all the advancement and skill of the present time. The neuropathic are, to a great extent. also psychopathic, but not insane as the word is ordinarily understood, although technically there is no difference between the psychoses of the neuropathic and what is medically termed "insanity," the difference being one of degree rather than of kind.

2. It is difficult or impossible in practice to place all the neuropathic in one group or location and all the psychopathic in another. They are inextricably comingled, the same persons frequently passing from one class to the other or belonging in both at once. The delirious, the maniacal, the epileptic, the frenzied. the auto- or hetero-intoxicated person of to-day is the quiet. rational. sane person of to-morrow, and many of the neuropathic are affected with psychoses.

3. If the turbulent, maniacal and otherwise objectionable patients are provided for in a wholly separate department, it is possible, where two separate institutions can not be afforded or maintained, to provide suitably for both neuro- and psycho-pathic on the same premises in detached buildings arranged for suitable classification. Constructive and administrative arrangements that are perfectly feasible would enable objectionable patients to be so located and so changed from time to time that appropriate surroundings will be provided for all.

4. The hospitals required may be either additions to existing institutions or separate establishments. The circumstances must differ in every community, and great flexibility will be necessary in the various arrangements according to members of different classes, location, means available, etc.

5. The word "insanity" has outlived its usefulness; it has no power as a definition in a technical sense, either medically or legally, and its popular use is confused and unsatisfactory. Etymologically the word is an absurdity. No acceptable definition of insanity has ever been formulated. "Psychosis" is a preferable term.

6. The legal questions relating to commitment to these hospitals would need legislative adjustment. Admission could be largely voluntary as to any hospital. Voluntary commitment as provided for legally now in many states of the Union would remove the difficulty in a large number of cases. It is understood no one should be under involuntary confinement without legal warrant, and suitable safeguards should be provided.

ABSCESS OF THE LUNG FOLLOWING ACUTE LOBAR PNEUMONIA.*

FLOYD W. McRAE, M.D.

ATLANTA, GA.

A decided impetus was given to the surgery of the lung in America by the paper of Bull in 1882 and the Address on Surgery by Murphy[1] of Chicago. This has been especially true of the surgical treatment of pulmonary abscess following pneumonia. When I selected this subject for my paper I was not aware that Eisendrath of Chicago was collecting statistics and working along the same lines. When, however, I began looking up the literature on the subject I found his most classical review[2] of "The Surgery of Pulmonary Abscess, Gangrene and Bronchiectases Following Pneumonia." The subject has been so carefully canvassed by him and the ground so thoroughly covered that I have been unable to find a single case of abscess of the lung not reported by him. I have therefore made free use of the material which he has collected and put in such excellent shape. In preparing the tables which follow this paper I have used his tables, simply eliminating the cases of gangrene, bronchiectases, probable tubercular abscess and abscesses following septic and traumatic pneumonia. I wish here to publicly acknowledge my indebtedness to Dr. Eisendrath and express my hearty appreciation of his painstaking, valuable work.

After eliminating the cases which I consider do not properly belong under the title of this paper, I find that he has collected in all 73 cases of "acute," "simple chronic" and "chronic putrid" pulmonary abscess, which, with my two cases, reported further on, make a total of 75.

The diagnosis of pulmonary abscess where the cavity is not surrounded by normal lung tissue should not be difficult. The history of an antecedent pneumonia with subsidence of the acute symptoms, followed by septic temperature with sudden expectoration of quantities of pus, then defervescence; more or less continuous purulent expectoration with exacerbations when the escape of pus is temporarily arrested, should lead one to strongly suspect this condition. The most valuable physical signs are dulness on percussion, large mucous râles and a metallic element in the sounds on auscultation and deep percussion. Bacteriologic examinations of the expectoration, revealing the pneumococcus and the pus-producing organisms with absence of the tubercle bacilli, in conjunction with the history and physical signs, make the diagnosis conclusive.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and [illegible] and approved for publication by the Executive Com[illegible] Walker, A. J. Ochsner and DeForest Willard.

[1] The Journal A. M. A., 1898.

[2] Philadelphia Medical Journal, Nov. 9,

The prognosis in cases of pulmonary abscess, that have persisted without marked improvement for more than four weeks, is so unfavorable under medical treatment that surgical intervention should be advised, when warranted by the patient's general condition. Cases not surgically treated grow more or less progressively worse until exhaustion or some intercurrent disease gives a happy release from suffering. The results of surgical treatment are most gratifying and growing progressively better as the operations are done earlier, more carefully and thoroughly.

My first case illustrates beautifully the immediate and continuous relief that may be obtained and the absolute restoration to health. My second case was a striking illustration of what the human organism can endure without great impairment of the vital organs and still retain its capacity to return to the normal when relieved of its burden. My experience in these two cases leads me to advocate opening the abscesses as low as possible, and in old cases much more extensive removal of ribs and diseased tissue. I should have done this in my second case except for the patient's miserable condition. He seemed almost moribund before completely under the anesthetic, and almost collapsed before I had completed even the simple operation of resection of short portions of two ribs. I believe this patient will also soon be restored to good health and the small existing sinus obliterated.

Later: Sinus closed; cure complete.

The following remarks on the pathology of pulmonary abscess, the physical signs prior to operation and the present condition of my two patients are by Dr. H. F. Harris, professor of pathology, Atlanta College of Physicians and Surgeons:

Abscess of the lung occasionally follows pneumonia, but it can not be said that it is a frequent sequel of this affection. It may result from either the common lobar pneumonia, or from the bronchial variety of the disease. As to the exact frequency with which this complication occurs there exists, so far as I am aware, no definite statistics, but that it is more frequent than is generally supposed there can be little question. This results from the fact that pneumonia may directly terminate in abscess, or this condition may come on some weeks after the individual has recovered from the acute pulmonary disease. When the latter occurs, there can be no doubt that our hospital statistics frequently fail to give a just idea as to the frequency of the complication, as under such circumstances the patient must frequently have been dismissed from the hospital before symptoms of breaking down of the lung were apparent, and doubtless many such instances have subsequently been regarded as tuberculosis following pneumonia.

As to the precise nature of the changes that occur in the lung when abscess begins to form as a sequel of pneumonia, we are in more or less ignorance; since, so far as I know, no one has made accurate histologic examinations at the time when the disease first developed. It is furthermore true that the exact conditions necessary to bring about this result are not as yet understood. It is assumed by some that this complication results from the presence of the pyogenic cocci, these acting together with the organisms that produce the pneumonic process. It, however, can hardly be doubted that the *micrococcus lanceolatus* is itself capable of bringing about a result of this kind under favorable conditions, and instances have been recorded where this bacterium was found in pure culture of the pus from abscess following pneumonia. Although, as before stated, the precise character of the histologic changes that occur in beginning abscess are not fully known, it is extremely probable that the tissues undergo alterations practically similar to those occurring in other parts of the body where abscess formation takes place. The pulmonary structures soften, undergo liquefaction and accumulate vast numbers of polymorphic nuclear leucocytes. These changes progress until an external opening is effected—this, in the vast majority of instances, being brought about by ulceration into a large bronchus and the expectoration of the abscess contents. After this occurs, it is probable that the size of the abscess does not further greatly increase, for if the patient does not quickly die, the cavity becomes walled off by newly-formed fibrous tissue in which, in old cases, lime salts may be deposited. Under such circumstances, the physical signs leave no doubt that the surrounding lung substance is never normal, but that a condition somewhat resembling broncho-pneumonia is constantly present. Although this state of affairs may continue even for years, the cases herewith recorded show beyond question that the lung may return to its normal condition after the abscess has been cured.

DR. HARRIS' COMMENTS ON THE TWO CASES.

Case 1.—P. R.—I examined this patient a short time before he was operated on and found, briefly, the following conditions; Patient is emaciated and pale. On inspection of chest the right shoulder is found to be considerably lower than the left, and neither on ordinary nor forced inspiration does the right chest expand to the same extent that is observed on the left side. On physical examination the upper and middle lobes of the right lung present no abnormalities, but extending from the third rib, where it joins the spinal column, downward and forward to the base of the lung in the right axillary line, there is dulness on percussion. On auscultation bronchial breathing is quite generally found along with a great number of small and large moist râles. Just beneath the lower angle of the scapula an area about two inches in diameter is found, in which on deep percussion a certain degree of resonance is elicited—the note produced having a distinctly metallic character. The "cracked pot" sound could not be elicited. On auscultation over this area the voice and the sounds produced in breathing are of a distinctly metallic character.

On May 26, seven months after the operation, this patient was again examined. Right shoulder is not perceptibly lower than the left and the chest expansion during inspiration almost normal. Percussion over the diseased area shows that there remains only a very slight degree of dulness, this evidently being the result of the thickened pleura. On auscultation, much to my astonishment, the vesicular murmur, even over the site of the wound, is absolutely normal and no râles are present.

Case 2.—Wm. W. R.—When first seen this man was greatly emaciated, very weak, and evidently extremely anemic. On inspecting the chest the left shoulder is found to be lower than the right and the left side of the thorax does not expand during breathing to anything like the same extent observed on the opposite side. On examination the upper lobe of the left lung is found to be normal, with the possible exception of its lower anterior border which may be involved in the diseased process that is present in the entire lower lobe. This, however, could not be made out with certainty on account of the great difficulties of making exact determinations in this particular locality. The lower lobe of the lung, beginning at a point where the 3d rib joins the spinal column and extending downward and outward to the lower border of the heart, presents dulness on percussion of a pronounced kind, and on auscultation bronchial breathing is everywhere heard, along with numerous moist râles. Outside the lower angle of the scapula and extending toward the spinal column, there is an area about four inches in diameter over which a distinctly metallic, tympanitic sound is produced on deep percussion. This, however, is not perceptible when the finger is tapped only lightly, there being under such circumstances merely dulness. The "cracked pot" sound could be elicited in a most striking manner. On auscultation the voice and the sounds produced in breathing are here found to be metallic in character, and it is noted that the pitch of the sounds produced in inspiration and expiration preserve their normal relationship, i. e., the expiration is of lower pitch than the inspiration.

This patient was again examined on May 25, about three months after the operation. The left shoulder is not quite on a level with the right, but does not drag downward to anything like the same extent observed before the operation. The chest expansion of the left side is not yet normal, but there is a decided improvement over the condition previously observed. On percussion it is found that posteriorly the lung is fairly resonant down to the lower border of the fifth rib and passing forward flatness is elicited from one to two inches lower than before the operation. In this area there are still numerous moist râles, but bronchial breathing is no longer present. Lower down, surrounding the wound in the chest, the lung is still flat on percussion and the breathing is bronchial. In this situation there has been no perceptible improvement, though this could scarcely be expected when the long duration of the affection is considered. It is astonishing that any improvement, even in the upper portion of this lobe, could have resulted under such circumstances, but that this has actually occurred there can be no doubt.

In both instances, repeated examination failed to reveal the presence of tubercle bacilli. There were, however, enormous numbers of the *Micrococcus lanceolatus*, and many of the ordinary cocci of suppuration.

AUTHOR'S NARRATION OF THE CASES.

Case 1.—P. K., male, 19 years old, single, American, insurance clerk. Had acute lobar pneumonia, right lung, March 29, 1900, followed by pleurisy. Confined to bed to May 12. After being up for three months began expectorating pus. About every twenty-five to thirty days would have intense pain lower portion of right side, expectorating quantities of purulent material with fetid odor, and be relieved. Pus would continue, in gradually diminishing quantities, twelve to fourteen days. Jolting, as horseback riding, etc., would cause pain and increase the discharge of pus. He became stooped antero-laterally, with considerable depression of right shoulder. I first saw patient during fall of 1900, and after physical examination of the chest and repeated bacteriologic examinations without finding tubercle bacilli, I advised operation, which was declined. The patient was in such poor physical condition that the family physician was unwilling to have the operation done. Patient spent the following spring and summer in the mountains of North Carolina without real improvement. In September, bacteriologic examination of expectoration for tubercle bacilli still negative. Operation consented to. Admitted to St. Joseph's Infirmary Oct. 18, 1901. Temperature ranging 98 to 100, pulse 80 to 100, expectorating large quantities of offensive pus. Continuous pain in right subscapular region over which area there was marked dulness. Mitral and aortic murmurs (hemic).

Operation.—October 22. Gas-ether anesthesia. Patient in antero-lateral decubitus. Incision along fifth rib anterior to posterior axillary line. Two inches of rib removed. Pleura greatly thickened, pus found upon aspiration. A vertical incision was made from the center of the first incision downward and an inch and a half of the sixth rib removed. Pleuro-costalis, pleuro-pulmonalis adherent and the latter continuous with thickened, indurated lung tissue and abscess wall. A circular excision of these structures a little larger than a silver dollar, opened well the abscess cavity, allowing the escape of two to four ounces of pus. This time considerable blood and pus coughed up, escaping through mouth and nose. Abscess cavity, about 3 inches in diameter, carefully wiped out with gauze, two drainage tubes with gauze (iodoform) placed in, and angle of wounds closed. Afternoon temperature 99, pulse 96, thence temperature, normal. Outer dressing changed October 23. Very little soiling. On second day drainage tubes and gauze packing easily removed. Moist, but not saturated with pus. Cavity clean and bright red. One tube replaced, cavity lightly packed with gauze. No cough, expectoration or pain after operation. Lung expanded rapidly; depression of right shoulder disappeared and cavity rapidly filling with granulations. Was gently wiped out every second or third day with iodoform gauze and drainage tube kept just within cavity until the 27th day, when only a sinus one-quarter inch by two inches remained. On the 40th day had clear respiratory murmur over the lung. Wound completely healed. Walks erect. Had gained 30 pounds and had been working as rodman in surveying corps for a week.

Case 2.—Wm. R. H., aged 59, married, laborer in saw mill. Health good until March 18, 1896, when he had acute lobar pneumonia, lower lobe of left lung, for about 10 days. Then severe symptoms subsided, but he began coughing, violent paroxysms, expectorating large "clumps" of pus. From March to August, of same year, he lost 50 pounds in weight. The expectoration of offensive pus continued from subsidence of pneumonia, always being increased after walking or talking for any length of time. After sleeping for 4 or 5 hours at night, in never lower than a semi-prone position, would, on awakening, expectorate great quantities of pus, which would almost run in a stream from his mouth. When walking around, the expectoration was so profuse that "he could be tracked by the clumps of pus." He could lie for only a few minutes on the right side, with left arm raised. Left lateral position or pressure of arm upon chest, causing pain and coughing. Pain almost constant over region of apex of heart. He had no night sweats or fever. Appetite poor. Admitted to Grady Hospital Feb. 28, 1902. Temperature 98, pulse 96. Complained of pain lower portion of chest, greatest intensity over apex of heart. Almost constant cough, expectorating large quantities of offensive pus. Could sleep only in sitting posture.

Operation.—March 3. Chloroform anesthesia. Incision 3 inches long, just beneath and slightly to axillary side of angle of scapula. Two inches of fifth and sixth ribs removed. Pleuro-costalis, pleuro-pneumonalis thickened, adherent and the latter continuous with the lining membrane of the abscess cavity. Pus found on aspiration. As abscess opened, 8 to 12 ounces of pus escaped. Several pieces of calcareous material of bony hardness were removed from the abscess cavity and torn loose from the lining membrane. A considerable area of thickened pleura was removed and the whole cavity scraped with a sharp curette. Cavity irrigated gently with normal salt solution; two large drainage tubes inserted and the whole cavity lightly packed with iodoform gauze. Coughing immediately relieved. On the fourth day tubes and packing removed and cavity irrigated with normal salt solution, tubes and packing replaced. After irrigation, patient could taste the salt solution and later the iodoform. Tubes and gauze removed and left out on the seventh day. Cavity irrigated daily. Considerable purulent discharge. Two days after drainage tubes were removed, again began having paroxysms of coughing, expectorating pus. Tubes replaced, cough stopped at once. After a slight exacerbation, soon after operation, temperature continued normal and pulse gradually improved. Appetite good, and when patient left the hospital April 23 he had gained 45 pounds. A small sinus from which a slight quantity of serous fluid escapes, still persists.

Later: Latter part of July sinus closed; cure complete.

SYNOPSIS OF TABLES FOLLOWING.

Cases.	Average Age.	Male.	Female.	Average Time. Pneumonia to Operation.	Adhesions Per cent	No Adhesions Per cent	Recovered. Per cent.	Improv Per cent	Died. Per cent	Total cases.
Acute	29 4 years (4 to 60)	27	13	31 3 days.	34 85	6 15	33 82 5	2 5.	5 12 5	40

THE SURGERY OF PULMONARY ABSCESS AND GANGRENE FOLLOWING PNEUMONIA. TABLE 1.—SIMPLE ACUTE ABSCESS.

Author.	Sex and Age.	Etiology and Duration.	Physical Signs Before Operation.	Adhesions Present.	Operation and Condition Found.	Result.
Körte.	Male, 37.	Pneumonia, left lower lobe, 3 weeks previously.	Dulness from angle of scapula down, with weak bronchial breathing and many râles.	Yes.	Pneumotomy; found cavity in left lower lobe, admitting two fingers. Second operation one month later to relieve accompanying empyema.	Recovery after 8 weeks.
Körte.	Male, 36.	Influenza, pneumonia 2 weeks previously.	Dulness posteriorly from angle of scapula downward, left side.	Yes.	First operation opened an empyema. Second operation performed 4 weeks later on account of pain to left of precordium. Abscess in left upper lobe opened.	Recovery in 8 weeks.
Körte.		Pneumonia 4 days previously.	Extensive dulness anteriorly to third rib, posteriorly to spine of scapula.	Yes.	Thoracotomy; circumscribed empyema opened. Dulness continued. Fever and sputum like that of an abscess. Second operation; opened encapsulated abscess of lung.	Recovery in 3 months.
Edward Martin, Philadelphia, unpublished.	9 years.	Pneumonia.	Faint dulness left of cardiac dulness and merging into it.	Yes.	Pneumotomy; half ounce of pus evacuated.	Recovery.
R. Matas, unpublished.	Male, 22.	Pneumonia.	Well-defined area of dulness over base of right lung, bronchial breathing; hectic fever.	Yes.	Resected 8th rib and evacuated nearly a pint of pus; no odor; cavity had rigid, rough wall; iodoform gauze packing.	Recovery.
W. J. and C. H. Mayo, Rochester, Minn., St. Mary's Hospital Report, 1901.	Female, 10.	Grippe, pneumonia 4 weeks previously.	Physical signs; located abscess in left lung; *x*-ray not of material aid.	Yes.	First operation failed to find abscess. Second operation two weeks later; opened abscess in front of previous opening.	Recovery.
H. Jablokow, Archiv. f. Kinderheilkunde. vol. 31, p. 278.	Male, 10.	Grippe, pneumonia 5 weeks previously of right lower lobe.	Dulness from third rib in front, from angle of scapula behind and spreading axillary regions. Decreased respiratory murmur and fremitus and moist râles. A tumor appeared 4 by 6 c.m. over the 4th to 6th ribs. On coughing frothy muco-pus came from wound.	Yes.	Evacuated four ounces of bloody pus from tumor. From incision could palpate cavity in lung (size of an egg).	Fever, etc., fell rapidly; fistula still present.
Green, Lancet, Jan. 24, 1901, p. 196.	Female, 6.	Pneumonia of entire left lung 4 weeks before.	Bulging and tenderness over 5th rib (ax. line). Large quantity pur. expectoration, dulness, tubular breathing & dec. fremitus.	Yes.	Opened abscess in lung with trocar as guide. Drained.	Recovered in a few weeks.
Mass. General Hospital.	Female, 36 mos.	Pneumonia 3 weeks.	One week after fluid was found in chest. About half cup of creamy fluid drawn off. Since then considerable pain in right side. Cough with white, frothy expectoration. Shortness of breath. A distinct bulging in axillary region of the side.	None.	Ether given. A portion of 5th rib removed. Opening made in right lung. Considerable hemorrhage and one and one-half pints pus evacuated. Patient also coughed up considerable pus and blood.	Recovery in 3 weeks.
Runeberg, Deut. Archiv. f. Klin. Med., vol. 41, 1887.	Male, 33.	Pneumonia 4 weeks before; no crisis; physical signs cleared up, but fever again began (remittent type).	Dulness from mid-axillary line to spine or scapula.	Yes.	Exploratory puncture in 6th intercostal space showed pus. Resected 6th rib. Entered cavity in lung with soft wall and evacuated pus. Drained. Temperature fell at once.	Recovered in 4 months.
Huber, Trans. Am. Ped. Assn., vol. 3, 1892.	Male, 4.	Pleuro-pneumonia one month before.	High temperature and respiration rapid. Bronchial breathing.	Yes.	Exploratory puncture showed pus. Drained.	Recovered 8 months later.
Quincke, Berlin Klin. Woch., 1888, No. 18.	Male, 23.	Left lower lobe, pneumonia 3 months before.	Dulness behind as high as fifth dorsal spine. Vocal fremitus absent and respiratory murmur decreased. Very fetid expectoration; marked fever.	None.	After application of zinc chlorid resected rib. No cavity found.	Recovered 2 months later.
Rochester Med. News, Jan. 20, 1894.	Male, 38.	Pneumonia of right middle and lower lobes 3 weeks before first operation.	Elastic fibers found in sputum. Tympany in inter- and infrascapular regions with amphoric breathing, and voice. Dulness below it.	Yes.	Resected 5th rib and drained. No relief, followed by pyemic symptoms. Three months later more extensive resection; cavity packed.	Recovered in 3 months after 2d operation.
Sewerin, Botkin's Hosp. Zeitung, 1896, No. 14.	Female, 22	Soon after an attack of croupous pneumonia, sign of a cavity.	Signs of cavity in axillary region.	Probably.	Incised and evacuated 350 c.c. pus with necrotic lung masses.	Recovered.

cet, Dec. 18, 189	emale, 21	Pleuro-pneumonia nine weeks before; daily expectoration of pint of pus and high fever.	Dulness over right lower lobe laterly and behind; coarse gurgling râles under right scapular and bronchial breathing.	Adhesions with encapulated serous exudate.	Chloroformed. Exploratory puncture showed pus. Resected rib and found irregular cavity of large size.	Recovery in 2 months	
Elsner, Medical News, March 25, 1899.	Male, 34.	Severe pneumonia 11 days before.	On 11th day symptoms of pus accumulation in middle lobe of right lung. Localization very difficult.	Yes.	Lung incised and drained. Incision followed by considerable hemorrhage. Found pneumococci and staphylococci.	Recovered.	
Elsner, Medical News, March 25, 1899.	Male, 26.	Pneumonia middle and lower lobes of right lung with delirium tremens just preceding operation.	Crisis followed by intense pain below scapula and in axilla and fever. Dulness and amphoric breathing.	Few adhesions.	Exploratory puncture showed pus. Resected rib and opened an abscess in lung just beneath pleura, containing half a pint of pus. Local anesthesia.	Recovery 2½ months after operation.	
Crerar, British Medical Jour., May 20, 1899.	Male, 9.	Right-sided pneumonia just before (4 weeks).	Four weeks after crisis had harassing cough, but no sputum. Marked emaciation, temperature, dull area toward axilla and from fifth dorsal spine down. Vocal resonance lost. Diagnosis of empyema made.	Yes, at upper part.	Could not find abscess at first, until several ribs resected. Opened cavity size of small orange in lung with soft, ragged walls Gauze packing.	Healed in 2 months after operation.	

TABLE II.—ACUTE GANGRENOUS ABSCESS.

Author.	Sex and Age.	Etiology and Duration.	Physical Signs Before Operation.	Adhesions Present.	Operation and Condition Found.	Result.	Result of Autopsy.
Körte.	41.	Pneumonia 1 month previously.	Marked dulness over lower and lateral aspects of left lung. Putrid sputum and odor.	Yes.	Circumscribed empyema opened, communicating with abscess in lung. Iodoform gauze drained.	Recovered in 7 weeks.	
Körte.	Male, 56.	Pneumonia 4 weeks before.	Dulness over right lower lobe laterally. Decreased respiratory murmur and fremitus. Puncture in 6th interspace showed thick putrid pus.	Yes.	Pneumotomy; large irregular cavity in right lower lobe opened.	Recovered in 6 weeks.	
Edward Martin (Philadelphia).	Male, 14.	Pneumonia.	Profuse and offensive expectoration, following subsidence of physical signs. Dulness over area size of hand at base of right lung, with large bubbling râles.	Yes.	Circumscribed empyema found under 9th rib, which was resected. Opening into pulmonary cavity found, and enlarged, and drained.	Complete but slow recovery.	
Edward Martin (Philadelphia). Unpublished case.	Child, age and sex not given.	Pneumonia followed by symptoms of profound septic poisoning and fetid expectoration.	All pointed to abscess cavity in right lower lobe.	Yes.	Two ribs resected and whole right lower lobe found in a condition of acute gangrene.	Death in 24 hours.	
Jas. H. Dunn (Minneapolis). Unpublished case.	Female, 35.	Pneumonia, left lower lobe 2 weeks before.	Chilled, expectoration of fetid pus. Sign of cavity.	Yes.	Resection of 6th and 7th ribs in posterior axillary line. Exploring needle showed pus. Cavity opened and drained.	Recovered in 9 weeks.	
Chas. A. Morton, British Medical Journal, Feb. 17, 1900.	....	Acute pneumonia 4 days previously.	Dulness from angle of scapula down. Tubular breathing.	None. Held up lung with forceps.	Sutured pleura and evacuated pus. No infection of pleura resulted.	Recovered in 4 months.	
W. J. and C. H. Mayo, St. Mary's Hospital Report, 1901.	Female, 42.	Pneumonia 3 months before.	Physical signs and *x*-ray not of marked aid in localizing cavity.	None.	Suture of visceral to parietal pleura. Second operation 5 days later, abscess drained; gangrene of lung.	Recovered.	
Quincke, Mittheilungen aus den Grenzgebieten, 1896; also Berl. Klin. Woch., 1888, No. 18.	Male, 32.	Atypical pleuro-pneumonia 10 weeks before.	Those of abscess in right lower lobe. Fever and putrid sputum.	None.	Zn Cl_2 paste used to produce adhesion. 12 days later pneumotomy.	Recovered in 4 months.	
Quincke, Mittheilungen aus den Grenzgebieten, 1896.	Male, 33.	Pneumonia 2½ years before. Fresh pneumonia probably cause of abscess.	Putrid sputum, containing elastic fibers. Behind on right side from 6th dorsal spine down dulness, bronchial breathing and metallic râles.	Yes, shown by lack of respiratory mobility and inspiratory retraction.	Exploratory puncture in 7th space showed pus. 8th, 9th and 10th ribs resected in scapular line. 3 days later gangrenous cavity opened and drained.	Recovered in 6 weeks.	
L. C. Smith, Lancet, July 20, 1889.	Female, 30.	Atypical pneumonia 9 weeks before.	Cavity symptoms at angle of right scapula. Putrid sputum.	Yes.	Exploratory puncture below angle of scapula negative. Pneumotomy with blunt dilatation of small cavities.	Improved, putrid odor disappeared.	
H. Jablokow, Archiv. f. Kinderheilkunde, Vol. 31, p. 278.	Male, 10.	Probable pneumonia 3 weeks before.	Extensive dulness over right lower lobe, with fine moist râles, and bronchial breathing. High fever, rapid breathing and marked fetid breath.	Yes.	Resected 7th rib in axillary line; entered cavity filled with putrid fluid and fine lung detritus. Removed a 5 cm. piece of gangraneous (sequestrum) lung. Greatly improved, yet fever and expectoration continued. Opened 3 cavities one month later by resecting rest of 7th rib.	Died 5 months later, of inanition, though general condition greatly improved.	Extensive adhesions of right lung. Around wound of operation many pus cavities filled with gangrenous particles, and communicating with several bronchi.

TABLE II, CONTINUED.—ACUTE GANGRENOUS ABSCESS.

Author.	Sex and Age.	Etiology and Duration.	Physical Signs Before Operation.	Adhesions Present.	Operation and Condition Found.	Result.	Result of Autopsy.
H. B. Meakin, British Medical Journal, 1896, Vol. ii, p. 747.	Male, 31, insane.	Pneumonia, base of right lung, May 20, 1896.	Three days after beginning of disease, area of dulness increased and noticed fetid breath. Dulness to clavicle and to left of sternum. No expectoration. High fever.	None.	Schleich anesthesia. Exploratory puncture, obtained one ounce of fetid, thick fluid. 6th and 7th ribs resected. On opening pleura, large quantity of fetid fluid escaped. No collapse of lung. Opened gangrenous cavity of lung, and drained.	Recovered.	
Openchowski, Zeit. f. Klin. Med., Band 16, 1896.	Male, 30.	Pneumonia 3 weeks before, followed by a sudden expectoration of large amount of fetid pus. (150-350 cm.) daily.	Decreased resonance over right upper lobe in front, from 3d rib down. Dulness further down with bronchial breathing and middle-sized moist râles. Later tympany, amphoric respiration and metallic râles in axilla.	Yes.	Resected 5th and 6th right ribs. Opened lung with cautery and entered cavity communicating with bronchus.	Recovered in 8 months.	
S. C. Smith, Lancet, 1880. Jan. 17, p. 86.	Male, 60.	Pneumonia, right lung, 14 days before.	Sudden fetid expectoration on 13th day after beginning of pneumonia. Tubular respiration around spine of scapula and below nipple. Diagnosed cavity of middle lobe.	Yes.	Opened cavity by incising between ribs and inserting tube. But little relief from toxic condition.	Died 4 days later.	
Hofmokl, Wiener Med. Presse, Vol. 32, Nov. 27, 1892.	Male, 32.	Pneumonia some years before, fresh attack previous (14 days) to operation, followed by gangrenous sputum.	On right side, behind, dulness, and large moist râles.	Yes.	Resected 7th rib at angle of scapula. Pleura looked gray and lung felt firm. Made 3 negative exploratory punctures. The 4th puncture 2½ inches into lung and showed small amount of putrid pus.	Recovered in 3 months.	
Edv. Bull, Nordiskt Med. Arkiv, Vol. 13, No. 17.	Female, 23.	Two months before had an acute bronchitis, later became putrid, followed by pneumonia of left upper lobe.	Signs of cavity. Exploratory puncture showed putrid pus causing infection of soft parts along line of puncture.	Yes.	Incision in 4th intercostal space. Drained.	Recovered in a short time.	
Moir, Lancet, Jan. 9, 1897.	Male, 23.	Left-sided acute pneumonia 4 weeks before. Symptoms of gangrene.	Septic symptoms. Physical signs best marked in axillary region and below spine of scapula.	Yes.	Incision over axillary region; evacuated portions of gangrenous lung from large cavity in latter. Inserted tube.	Recovered 5 weeks after operation wound was healed.	
Jayle & Jaffray, Soc. Anatomique, 1893.	Male, 41.	Pneumonia of righ lung 4 weeks before.	Dulness and absence of respiratory sound over base of right lung. Sudden expectoration of large amount fetid pus. High fever.	Yes.	Local anesthesia. Incision in 8th intercostal space, and evacuation of large amount of fetid pus.	Died one week after operation.	Found cavity occupying greater part of right lower lobe, into which several bronchi opened.
Hans Kohn, Deut. Med. Woch., 1898, 313, Vereins Beilage.	Male, 48.	Right upper lobe influenza. Pneumonia just before onset of gangrene symptoms.	Indistinct sign of a cavity in right lower lobe. X-Ray showed shadow size of palm of hand over lower lobe.	Yes.	Resected 8th, 9th and 10th ribs, but a tear in adhesions gave rise to pneumothorax; discontinued operation. After resorption of pneumothorax (2 weeks) made exploratory puncture, followed by severe hemorrhage from mouth.	Died immediately after puncture. Suffocation caused death, in spite of tracheotomy.	Found a cavity occupying lower lobe. Hemorrhage had not come from this cavity.
Phillips & Nash, Lancet, Nov. 21, 1896.	Male, 36	Pneumonia 4 weeks before, followed by septic symptoms and fetid breath.	Dulness over 5th rib in right axillary line, decreased respiratory sound, vocal resonance and fremitus.	Yes.	Exploring needle drew fetid pus from the 6th intercostal space. Resected 1¼ inches of 6th rib and opened gangrenous cavity in right lower lobe.	Healed one year after operation.	
Tuffier, Bull. de la Soc. de Chir., 1895, p. 765.	Male, 60.	Pneumonia 6 weeks before, followed by persistent hemoptysis, and odorless sputum.	Decreased resonance behind about angle of scapula, loss of fremitus, bronchial breathing and subcrepitant râles.	Yes.	Resected 7th rib and opened cavity size of head of fetus in lower lobe, from which brownish malodorous pus escaped. Gauze packing. Severe hemoptysis 6 days after operation.	Recovered.	
Ramsay, Annals of Surgery, 1890.	Male, 32	Pneumonia a few weeks before. Soon after crisis gangrene began.	Lower one-third right lung dull. Respiratory murmur absent. Exploratory puncture showed greenish pus.	Yes.	Resected 3d rib in axillary line. Opened cavity 2 cm. long, containing cupful of gangrenous-looking fluid. Drained.	Recovered in 6 weeks.	

TABLE III.—SIMPLE CHRONIC ABSCESS.

Author.	Age and Sex	Etiology and Duration.	Physical Signs Before Operation.	Adhesions Present.	Operation and Condition Found.	Result.	Result of Autopsy.
Körte, Archiv. fur Klin. Chir. Vol. 63.	Male, 52.	Pneumonia 2 years before.	Dulness and *small moist râles* over middle lobe. X-ray showed distinct cavity, middle of right lung.	None.	Catgut suture of pleura. Marked dyspnea during operation. Only once small quantity of pus obtained.	Died 3 hours after operation.	Showed a system of bronchiectatic small cavities, surrounded by pneumonic areas. Only the smallest cavity had been opened.
Körte, same.	Male, 21.	Pneumonia 6 months before.	Dulness, tympany, and amphoric breathing, with large moist râles over right upper lobe.	Yes.	Pneumotomy. Pus evacuated from bronchiectatic abscess found in right upper lobe.	Recovered in 18 weeks.	
Körte, same.	Female.	Influenza-pneumonia 2 years before.	Over left lower lobe marked dulness, bronchial breathing. Resonance decreased and dry râles over rest of lung. Later amphoric breathing over left lower lobe before operation.	Yes.	Bronchiectatic pus cavity opened. Later a communication with a second cavity established.	Died three months later.	Stenosis of main bronchus. Extensive cavity in left lung.
Körte, same.	Female, 41.	Influenza-pneumonia of right lower lobe one year before.	Posteriorly on right side, dulness increased from above down over upper portion; bronchial breathing from angle of scapula down; light amphoric breathing.	Yes.	Small, circumscribed empyema opened. Also opened abscess in right lower lobe.	Died 7 days after operation, of fresh pneumonia of R. U. L.	Showed that operation had opened walnut-sized cavity in right lower lobe, but there were smaller ones present not opened.
Carl Beck, New York, N. Y. Med. J., Aug. 28, 1897.	Male, 31.	Pleuro-pneumonia one year previously.	On right side in front; tympany and râles and bronchial breathing.	None.	Resected 8-10th rib. One ounce pus evacuated. Some odor.	Healed 2 months after operation.	
Karewski. Arch. f. Klin. Chir., Vol. 67, p. 555.	Female, 35.	Left pleuro-pneumonia 4 months previously.	Dulness from *angle of scapula* down. High temperature.	Yes.	Opened abscess, size apple, in lower left lobe. No communication with bronchus found.	Recovered.	
Quincke, Berl. Klin. W., 1888, No. 18.	Male, 26.	Pneumonia 2 years before in left lower lobe.	None given.	None.	Zn Cl_2 paste applied and 9th rib resected. Three weeks later pus discharged through wound.	Alive 12 years later (1896), with fistula.	
Quincke, Mittheilungen aus den Grenzgebeiten, 1896.	Male, 25.	Double pneumonia 2 months before, complicating older bronchiectases.	Periodical expectoration of large quantities of pus. Dulness over 8th space (left). Bronchial breathing, metallic râles. Dulness from 5th left rib down in front. Later amphoric breathing and large moist râles.	Only partially before paste used.	Zn Cl_2 paste to cause adhesion; 9th, 10 and 11th ribs resected. Opened into cavity communicating direct with bronchitus. After operation, sputum greatly decreased.	Recovered in 2 months.	
Quincke, same place.	Male, 34.	Pneumonia 17 years before, and again 2 years before.	Respiratory mobility decreased on left side. From 7th dorsal spine down dulness; bronchial breathing, metallic râles. Paroxysmal expectoration of large quantities of non-fetid sputum.	Doubtful before paste used.	After paste (Zn Cl_2) used, pneumotomy, five weeks later. Pus evacuated and cavity drained.	Much improved; still has fistula.	
Osler and Halstead, Johns Hopkins Hosp. Bulletin, Dec., 1890.	Male, 60.	Pneumonia several times. Exact date not known. At intervals hemoptysis and putrid expectoration for years.	Loud resonant râles, amphoric breathing, and metallic râles in left axilla. Loud bubbling râles at base of left lung. Respiration, 40; temperature, 100. 3-600 c.c. Fetid expectoration daily.	Yes.	Resected 4th and 5th ribs and opened freely a series of cavities.	Died 3 days after operation. Too weak to react.	Showed that they had opened into a system of large bronchiectatic cavities in left upper lobe.
Kijewski, Centralb. f. Mitth. aus den Grenzgebieten der Inn. Med. und Chir., No. 4, 1901. Also Gazette Lekarske, No. 4, 1897.	Male, 32.	Right-sided pleuro-pneumonia, followed by a severe dyspnea and cyanosis some time before.	Pyemic type of fever. Dulness over right lower lobe.	Yes.	Resection of 10th rib after successful exploration had shown pus. Lung curetted and packed with gauze. Fever continued for some time.	Recovered.	
McRae, Atlanta, Ga.	Male, 19.	Lobar pneumonia, 3 weeks later purulent expectoration began. 1 year, 7 months previous to operation.	Third rib at spine to base of lung, right axillary side dulness, bronchial breathing, small and large moist râles. Outside lower angle scapula, area 2 inches in diameter, metallic resonance, voice sound metallic in character.	Yes.	Fifth and sixth ribs resected; aspirated pus; cavity 3 inches in diameter in lung opened; tubular and gauze drainage; fever and cough disappeared immediately.	Recovered rapidly.	

TABLE IV.—CHRONIC PUTRID ABSCESS.

Author.	Sex and Age.	Etiology and Duration.	Physical Signs Before Operation.	Adhesions Present.	Operation and Condition Found.	Result.	Result of Autopsy.
Körte.	Male, 33.	Pneumonia 10 months previously.	Tympany, gurgling râles, amphoric breathing below right clavicle and in axilla.	Yes.	Curved incision. Pectoral muscles divided. Exploratory puncture negative. With thermo-cautery *opened* large cavity filled with fetid fluid, and gangrenous lung.	Recovered in 18 weeks.	
Körte.	Male, 29.	Pneumonia 2 years previously.	Tympany in front. Dulness behind, over left upper lobe; no respiratory murmur over entire lung. Many râles over dull area. Typical 3-layer fetid sputum.	None.	Pleura sutured. Marked cyanosis. No further operative measures.	Died four days after operation.	Entire left apex composed of a system of communicating bronchiectatic cavities.
Körte.	Male, 23.	Duration, 7 years.	From angle of scapula down, bronchial breathing and dulness.	Yes.	Exploratory puncture revealed putrid pus. Pneumotomy. Putrid abscess emptied; left lower lobe near it was encapsulated empyema.	Recovered in 4 months.	
Körte.	....	Pneumonia, 5 months previously.	Absolute dulness; no respiratory sounds from 3d rid down, on right side. Diagnosis before operation was putrid pyema, and gangrene of lung.	Yes.	Thoracotomy. Pus evacuated. *No communication* found with abscess cavities. Patient remained septic.	Died in 10 days.	Showed two large abscesses in right lower lobe, not opened and diffuse bronchiectasis.
F. Krause.	Male, 36.	Pneumonia 9 months previously of left lower lobe.	Dulness, amphoric breathing, moist metallic râles near angle of scapula. Lower down, dulness, diminished respiratory sound and fremitus. Bad odor to expectoration and elastic fibers.	None.	Pleural cavity tamponed, opened 5 days later, when adhesions were found. Cavity in middle of lower lobe opened, size of an apple, containing putrid fluid, and large sequestrum of lung tissue.	Recovered in 3 months.	
Hadra, Centralblatt f. Chirurgie, 1897, p. 103, supplement.	Female, 38	Severe pleuro-pneumonia 8 years previous, since then invalidism.	Large quantity of putrid sputum. X-ray showed shadow entire left lung, heart displaced. Over right lower lobe dulness, and when full expectoration, tympany. Exploratory puncture negative.	Yes.	Pneumotomy, abscess cavity opened.	Recovered.	
Krause.	Female, 19	Pneumonia of left lower lobe and left-sided pleurisy with effusion, 6 months previously.	Dulness over left lower lobe.	Yes, at first operation; at second, lung *retracted.*	At first operation found empyema with greatly thickened pleura. Fever and expectoration increased after operation. Sputum putrid and contained elastic fibers. No physical sign of a cavity. A second operation, decorticalized the lung and looked for abscess cavity in vain over both uper and lower lobes. Two abscesses opened spontaneously into dressings.	Healed 5. months later.	
Jas. H. Dunn (Minneapolis). Unpublished case.	Female, 22	Pneumonia 4 years previously.	Expectorated cupful fetid pus daily, usually at one time. Signs of cavity on right side posteriorly.	None.	Two operations; one between scapula and spine; other in axilla. Some pus discharged from posterior opening, but no improvement, probably large cavity not opened.	Died 1 year after operation.	
Wiemer, Centralblatt f. Chirurgie, 1898, p. 183.	Male, 33.	Pleuro-pneumonia 2 years before.	Dulness over left lower lobe. Tympany in axillary and angular line. No respiratory mobility. Putrid sputum in large quantities.	Yes.	Resected 8th-10th ribs; opened cavity with cautery, size adult fist. Contained large sequestrum. On 4th day after operation found a second cavity.	Healed in 6 weeks.	
Williams and Marshall, Lancet, Dec. 30, 1882, p. 1107.	....	Chronic pneumonia of both lungs, and fetid expectoration, for 1 year.	In right lung symptoms of a cavity.	Probably.	Inserted trocar and drained cavity.	Died 6 weeks after operation.	Multiple bronchiectases in right lung. Largest had been drained. Death due to gangrenous cerebral abscess.
Priestley, Leech, Lancet, Jan. 13, 1894.	....	Pneumonia 6 months before, followed in 2 months by fetid expectoration.	Dulness from 2d rib down on left side with absent vocal fremitus and resonance. Respiratory murmur decreased. No elastic fibers. No signs of cavity.	Yes.	Exploration in 2d interspace showed pus. With needle as guide, introduced drain. Pneumonia 2 weeks after operation. No ribs resected.	Recovered 8 months after operation.	
Quincke, Berl. Klin. Woch., No. 19, 1887.	Male, 26.	Pneumonia 2 years before; since then fetid expectoration.	Dulness from 4th dorsal spine down, and as far anterior as axilla. Loud amphoric respiration, and voice. No change with changed positions.	None.	Resected 9th rib; found no cavity, but 3 weeks pus discharged from wound spontaneously. Second resection 6 months later to close cavity.	Discharged with fistula. Able to work.	

Quincke, Berl. Klin. Woch., No. 18, 1888.	Male, 32.	Atypical pneumonia 3 months before.	Dulness on right side, with no sharp boundaries, to spine of scapula and mammary line. Loud bronchial breathing and metallic râles. Very purulent fetid sputum.	None.	Zn Cl_2 paste in 8th intercostal space, followed by adhesion. Resected 8th and 9th ribs, and again applied zinc paste. After days later abscess opened.	Recovered in 4 months.	
Burgess and White, Lancet, April 16, 1898.	Female, 25	Pneumonia (?) 3 years before.	Hectic fever, large amount putrid sputum expectorated. Lower left lobe dull. Decreased vocal fremitus and resonance.	Yes.	Found circumscribed pleural effusion beneath it; abscess drained.	Recovered in 2 months.	
Sutton (quoted by Mosler), "Lungen-Chirurgie," 1883, Wiesbaden.	....	Acute attack pneumonia 5 years before; 2 years later a severe hemoptysis.	Signs of cavity in left lower lobe, with fetid expectoration.	Yes.	Incision in 6th intercostal space. Drained. Daily irrigation with carbolic solution.	Died suddenly on 31st day.	No cause found for death. Cavity occupied entire lobe.
Oehler, Munchener Med. Woch., 13, Oct., 1891.	....	Three years before had gangrene following pneumonia of left lower lobe. No cavity signs. Shortly before operation had after influenza a fresh pneumonia.	Chills, dyspnea, dulness, bronchial breathing, and metallic râles.	Not at first, but at second operation (4 weeks later).	Exploration negative. Seventh rib resected, followed by pneumothorax. Latter soon disappeared. Second operation (4 weeks later) found pleura adherent; could not find cavity but inserted tube. On second day pus discharged.	Still had fistula.	
Kummell, Centralblatt fur die Grenzgebieten der Innern Medicin und Chirurgie, 1901, No. 3.	Female.	Left lower lobe pleuro-pneumonia, 2 years before.	Not given.	Yes.	Resected 6th and 7th ribs. Puncture. Thermo-cautery. Very severe hemorrhage. Cavity size of egg, communicating with large bronchus.	Small fistula after 6 months.	
Quincke, Mitth. a. d. Grenzgeb. d. Inn. Med. u. Chir., 1896.	Male, 34 (Case 6).	Influenza, pneumonia 1½ years before.	Over left apex in front signs of cavity. Dulness behind, marked from 5th dorsal spine down; bronchial breathing, large moist râles.	Yes.	Resected 3d rib in axillary line. Incision into cavity evacuated fetid pus and mucus.	Died 1½ hours after operation.	Death due to weakness soon after operation. Small bronchiectatic cavity in upper lobe; system of cavities in lower lobe; one opened.
Northrup and McCosh, N. Y. Med. Journal, vol. 1, 1897.	Female, 23	Influenza, pneumonia, 6 months before.	Flatness from 3d rib down over right lung in front. Absence of respiratory sound and râles.	Yes.	Resected 6th rib and opened abscess in lower lobe, containing 3 ounces of thick and very fetid pus. Severe shock followed.	Recovered in 3 months after operation.	
Blunt, Lancet, 1888, Vol. 1, p. 622.	Male, 20.	Pleuro-pneumonia of right side; 2 weeks later fetid expectoration, which continued to time of operation, 3½ months later.	Hectic fever, sweats. Exploratory punctures showed fetid pus.	Yes.	Resected rib 1 inch below angle of scapula; used needle as guide, and opened gangrenous cavity. Drained.	Recovered in 6 weeks.	
Tuffier, Bull. de la Soc. de Chir., 1895, p. 765.	Male, 41.	Pneumonia with fetid expectoration 4 months before.	Dulness in front over right lung, amphoric breathing and moist râles. Severe hemorrhage 5th day after operation.	Yes.	Incision in 3d interspace, opened cavity size of turkey egg. Opened another cavity above it; both contained black blood mixed with lung débris.	Recovered in 3 months.	
Eisendrath.	Male, 60.	Right lower and middle lobe pneumonia 2 years before; since then fever, expectoration of large quantity of pus (3 pints daily), frequently fetid; emaciation; dyspnea, etc.	Respiration, 60; pulse, 126. No change in percussion anteriorly over right lung. Behind from scapula down area of dulness, size of palm of hand; also some bulging of intercostal spaces here. Over this area a few moist râles to be heard. Diagnosis made of gangrene of lower lobe.	Yes.	Resected 8th and 9th ribs under angle of scapula, entered free pleura cavity, upper lobe collapsed, marked dyspnea and cyanosis. Lower lobe found adherent in front. Resected 9th and 10th ribs in anterior axillary line, pleura adherent; opened a circumscribed empyema, and beneath it opened gangrenous cavity in lower lobe, and a small cavity in middle lobe containing pus. Drain and gauze inserted.	Died 12 hours after operation.	Found cavity size of fist in right lower lobe (gangrenous). Adhesions bound lower lobe to chest wall. Had also opened one of a series of bronchiectatic cavities in middle lobe. Some hemorrhage into pleura cavity.
McRae, Atlanta, Ga.	Male, 59.	Left lobar pneumonia, followed 10 days by large quantities fetid pus; constant chest pain; slept sitting until operation, 6 years after pneumonia.	Third rib, at spine, to lower border of heart, dulness, bronchial breathing and moist râles. Angle of scapula to near spine, area 4 inches in diameter, metallic tympanitic sound on deep percussion; tapped lightly, none.	Yes.	Fifth and sixth ribs resected under angle of scapula; aspirated pus; thickened pleura removed; pus cavity, size of fist, in lung opened; 8-12 oz. pus, and calcareous deposits; tubular and gauze drainage.	Two months later, cavity 1½ inches in diameter, fistula; respiratory murmur clear to cavity. Two mos. later sinus closed; cure complete.	

THE INOPERABLE NATURE OF THE PULMONARY TUBERCULAR LESION.*

HORACE J. WHITACRE, M.D.
CINCINNATI, OHIO.

In no department of surgery have the advances of the past few years been more signal than in that which pertains to the surgery of the chest. Conditions which, as recently as ten years ago, were considered to be irremediable by any method of treatment or were, perhaps, classed among the hopeless medical cases, have now been transferred to the domains of surgery and surprisingly good results have been obtained. The pericardium and the heart have been invaded; the mediastinum has been employed as an avenue of approach; lesions of the pleura that have previously been considered as hopeless have been brought within the pale and the surgery of the lung has become established on a firm scientific basis.

Perhaps the most fascinating part of chest surgery is that which concerns the lung, since it is here that best results have been obtained. Acute simple abscess of the lung and acute abscess following acute gangrene of the lung may now be treated medically for from four to six weeks. Then should the healing process fail to progress favorably, it is the opinion of the best observers that this case becomes surgical and that the cavity should be drained from outside. Such operative treatment has resulted in the recovery of 90 per cent. of simple abscesses and 61 per cent. of acute gangrene abscesses, while a small percentage in each are improved. The operative treatment of abscess following the lodgment of a foreign body has been somewhat less successful but is an imperative operation. The operation for chronic abscess of the lung has not thus far yielded good results, yet the results following chronic lung gangrene abscesses are very encouraging. The treatment of empyema has been very greatly facilitated by knowing that a majority of cases of empyema are the result of the rupture of a lung abscess into the pleural cavity. The treatment of bronchiectatic cavities by surgical operation has been so extremely unsatisfactory by reason of its high mortality (80 per cent.) and a failure to obtain results, that it can not be considered to be a justifiable procedure except in those few cases in which the cavity is single and of the saccular variety. The extirpation of echinococcus cyst of the lung has yielded 91 per cent. of recoveries. As a further element in the development of surgery of the lung, it must be stated that a technic and an experience has been developed which convinces us beyond question that the pleural cavity can be opened for operative procedure on the lung, even for abscess, without the slightest reference to the presence or absence of pleural adhesion; that the lung tissue can be incised, excised and sutured; that an individual can live with but one lung; and lastly, that the cavity left after the collapse or excision of lung tissue may be filled by the excision of the ribs and caving in the chest wall.

It is but natural that the very first success in lung surgery should suggest the question, can this be applied to that most dreaded of all lung conditions—pulmonary tuberculosis? Nor is it surprising that each new success of lung surgery should call forth every and repeated effort on the part of the surgeon to bring some part of or the entire disease within the surgical field. Such attempts have been made, many cases are reported and some writers already insist upon the excision of diseased tissue and the drainage of cavities in all cases of pulmonary tuberculosis where this is possible.

HISTORICAL SUMMARY.

It is but a natural inference that tuberculosis of the lung remained a *noli me tangere* up to the introduction of aseptic surgery. Mosler first took advantage of this surgical advance and caused the exposure, incision and cleansing of a tubercular cavity by the surgeon Heuter, in 1873. This operation was not followed by a favorable result. The animal experimentation of Schmidt, Bloch and more particularly, Gluck, demonstrated beyond question, however, that portions or entire lobes of the lung could be safely resected. Then the circle of proof seemed to be completed when Biondi resected and completely cured an artificially induced tubercular focus in the lung. Pneumectomy at once replaced pneumotomy and the radical removal of the tubercular focus seemed to be as rational as that of malignant tumor. This belief was only strengthened by the demonstration of the tubercle bacillus in 1882 by Koch.

Ruggi attempted the excision of a tubercular focus in the lung of a man and the patient promptly died. This result served as a lasting set-back to surgical enthusiasm in this direction, and not until the discovery of Koch's tuberculin was interest regained. It was now supposed that the tuberculin would destroy all tubercle bacilli, and that there would be left to the tissues the burden of casting off the tuberculous tissue, of overcoming the mixed infection and healing destruction cavities. Tuberculosis seemed to be cast at a bound into the realm of surgery. The exposure and incision of cavities (pneumotomy) now seemed to be the operation indicated. Tuffier has collected the statistics of 27 cases treated by this method up to 1897. None of these patients were cured of tuberculosis, many died as a result of the operation, and only one survived for more than a few months. This one case (of Sonnenberg) lived five years, and the cavity filled up with scar tissue, yet tubercle bacilli never disappeared from his sputum and at the time of his sudden death a disseminated miliary tuberculosis and a cavity the size of a hazel nut were found in his lung. It is, of course, needless to state that this intoxication was soon over and that nothing is now heard of the method.

SUMMARY OF REPORTS FROM MANY AUTHORS.

Tuffier has found the apex of the lung the seat of a tuberculosis in which the pleuritic adhesions were coextensive with the tubercular process and in which the entire tubercular area was excised as though it were a tumor. This case is reported recovered.

Lawson of Hull has excised an apex with persistence of a sinus.

Doyen has performed a similar operation.

Porrit recommends the excision of all tubercular tissue possible and states that the excision must be thorough, inasmuch as an error of one-half inch may jeopardize the results of the operation.

Lane states that there must be a time in every case of undoubted tuberculosis of the lung when surgical cure is possible, and enters a plea for early operation in such cases. *He would advise the excision of tuberculous tissue.*

Ferguson has reported a case in which a fluctuating swelling under the clavicle was incised and found to be a tubercular abscess secondary to pulmonary tuberculosis. The lung was subsequently opened, no cavity was found in the tubercular mass, which was located opposite the fifth rib, but one dram of iodoform powder was placed in the center of this mass and the wound in the lung firmly packed with iodoform gauze. The patient recovered and gave no evidence of tuberculosis at the time of the report.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Naentjens reports a similar case in which a small swelling appeared in the axilla during the course of a slowly progressing pulmonary tuberculosis with cavity formation. This swelling was incised, found to contain pus and to communicate with the lung cavity. The lung cavity was opened and the wound tamponed with iodoform. Sinus persists. Patient improved but not well.

Malbot reports a case of tuberculosis in both lungs. In left upper lobe a superficial cavity had led to inflammation in the skin over second intercostal space. A free incision in second intercostal space opened lung cavity.

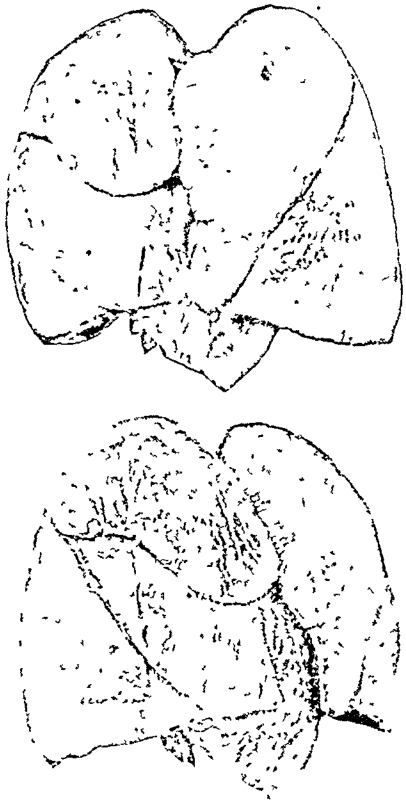

Fig 1.—Normal lungs with bronchi and blood vessels filled with Kaiserling solution. Anterior views

Recovery in three months with an improvement in his general condition.

Freyhan has collected 13 cases in which cavities of the lung had been drained. Two recovered and the remainder died either immediately from the operation, or at varying intervals after the operation from tuberculosis. One of these cases of recovery is that of Sonnenberg, included under the table of Tuffier.

Wills reports 2 cases in which the drainage of tubercular cavities in the base of the lung resulted in the recovery of the patients from their tuberculosis. He advises the general application of the operation.

Turban proposes to attain a condition of rest and furnish conditions favorable for cicatrization of cavities and areas of destruction by extensive thoracoplasty, in which a number of ribs are excised in considerable part and the chest wall is allowed to fall in on the contracting lung. This operation is entirely extra-pleural.

Spengler has operated according to the same method.

Porrit reports three cases operated on by this method, combined with excision of lung tissue with three deaths.

Franke has combined the drainage of a cavity with thoracoplasty and obtained an improvement in the condition of the patient, but the sinus persisted for two years, when the patient died of an intercurrent disease.

Garre has recently stated that operation for pulmonary tuberculosis is indicated under three conditions: 1. The broad opening, drainage and tamponage of a cavity is justified in those cases where there is a damming up and decomposition through mixed infection by the pyogenic cocci and the appearance of septic fever. 2. The broad exposure, excision of infiltrated lung and extensive thoracoplasty is indicated where isolated cavities exist and where the tubercular focus is limited to the lower lobe. 3. The immobilization of the chest wall or of the lung is recommended by the production of an artificial pneumothorax according to the method of Murphy.

Quincke, who has made the most signal contributions to the surgery of the lung, recommends immobilization of chest by thoracoplasty when the lesion is located in the apex. He has drained cavities with unfavorable results. He believes that only the fibroid type of phthisis should be subjected to operation, and then to the operation of immobilization.

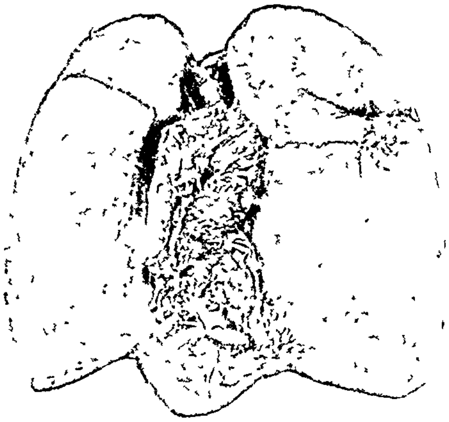

Fig 2—Normal lungs (Posterior view.) Shows the high position of the fissures posteriorly. The irregularity in the right lung is due to an adhesion and to a creasing during the hardening process

Franke joins with Quincke in this belief.

Hearne gives as one of the indications for surgical intervention in diseases of the lung, a single tubercular abscess with retained secretions, high fever and a localized tubercular involvement of the lung tissue.

Murphy has recommended the complete immobilization of the lung by injecting nitrogen gas into the pleural cavity for the purpose of inducing an artificial pneumothorax. By this means the lung is completely collapsed against the spinal column.

Lemke reported 53 cases in 1899 treated by this method with results which seemed to be favorable. Dr. Lemke has stated in a recent personal letter on this subject that he has been using the method continuously during the past four years and that his results are very gratifying.

POSTMORTEM INVESTIGATIONS.

With a view to determining the possibilities of operative interference in pulmonary tuberculosis, I have spent some time during the past year and a half in the study of the lesion as presented in the autopsy room and the hospital wards. This study has been pursued in autopsy material by serial sections made from lungs prepared as follows: The thoracic contents were removed *in toto,* then the bronchi and blood vessels were filled with a Kaiserling solution to a degree that would restore the size of the lung to that which it possessed in the living state. The lungs were then immersed in Kaiserling solution until hardened. Normal relations were preserved in this way and the lesion studied in serial section. In the pursuit of this study I am greatly indebted to Dr. B. F. Lyle, physician, and Dr. Louis E. Cook, pathologist, to the Cincinnati Branch Hospital for contagious diseases. The study of clinical material has been conducted through the further kindness of Dr. Lyle as a review and statistical arrangement of 978 cases of pulmonary tuberculosis treated at this hospital during the past five years.

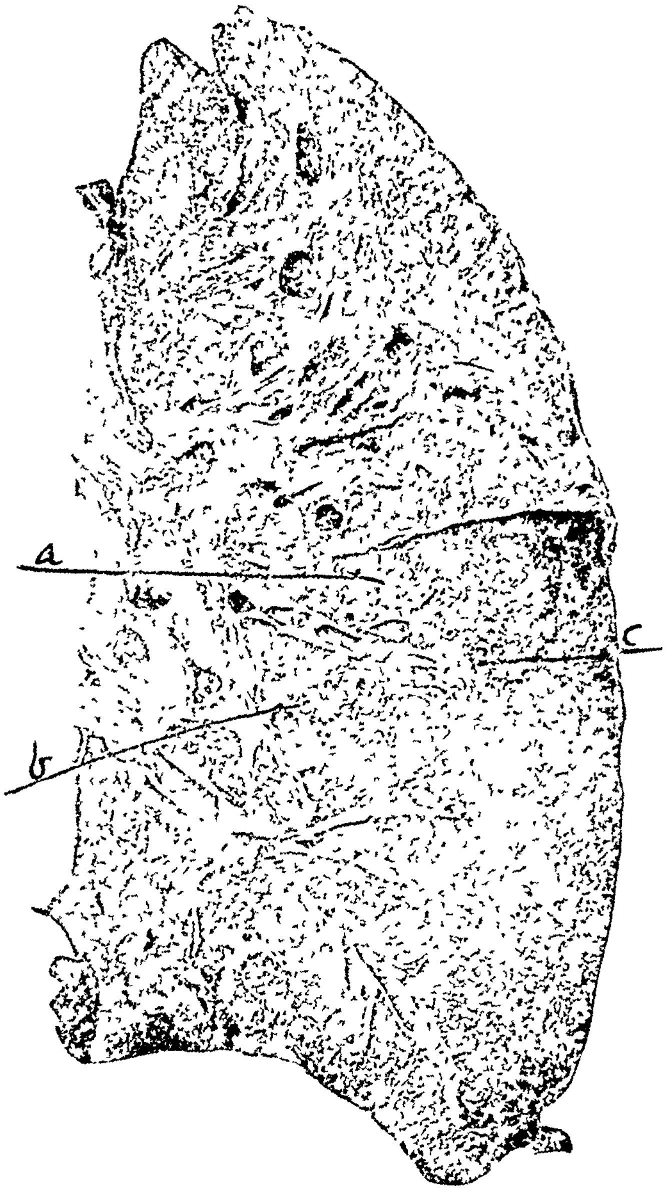

Fig 3—Tubercular lung. The lesion was diagnosed as a lesion confined absolutely to the upper part of the upper lobe No refinement of physical diagnosis could have detected the tubercles at *a, b* and *c.*

It has been my purpose to determine the most common location of the pulmonary tubercular lesion; the extent of lung tissue involved in the course of the development of the different stages of the disease; the location of the secondary involvement; the possibility of excising the lesion in its first or second stage; the presence and extent of pleuritic adhesions; the location of cavities, their accessibility, their operability; the frequency with which a tuberculous cavity becomes an acute abscess; and lastly, the nature of the usual septic process in phthisis.

A study of the distribution of the lesion would show that in 0.93 per cent. of the cases one apex alone was involved. In 1.0 per cent. both apices were involved. In 1.3 per cent. one upper lobe and the opposite apex were involved. In 3.6 per cent. both upper lobes were involved. In 8.5 per cent. two upper and one lower. In 2.6 per cent. one upper and one lower on the same side. In 1 per cent. the entire lung on one side and the apex on the opposite side. While in 74.9 per cent, of these cases both upper and both lower lobes were involved. In estimating the extent of lung involvement it has been considered that when the physical signs of tubercular involvement extended below the fifth rib posteriorly, that the apex of the lower lobe was involved. An apex involvement of the lower lobe is included under the heading of lower lobe involvement.

TABLE SHOWING DISTRIBUTION OF LESIONS

	Per Cent
One apex alone	.93
Two apices alone	1.00
One upper lobe alone	2.30
Two upper lobes alone	3.60
One upper and one lower in same side	2.60
Two upper and one lower	8.50
One upper and two lower	1.20
One upper and opposite apex	1.30
One upper and lower and opposite apex	1.00
Two upper and two lower	74.90

In 14.5 per cent. of the cases the patient gave a history of having had pleurisy at some time during the past few years, while physical examination revealed pleurisy in 30 per cent. of cases. *In none of the cases coming to autopsy were the lungs free from adhesions.*

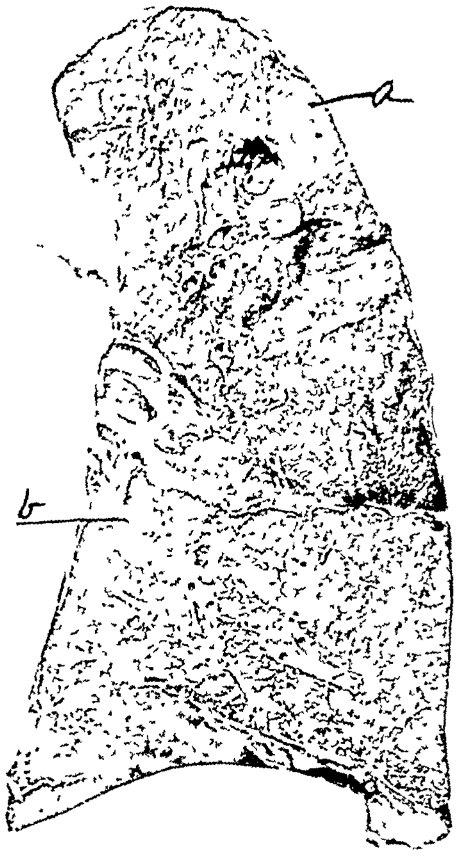

Fig. 4—Tubercular lung A most careful physical examination located the sole lesion at (*a*) with apex free At the autopsy only one other area was found at (*b*), so remote from the surface that no clinician could have detected it.

Emaciation of a pronounced character was present in 82.6 per cent. of cases, slight in 14.6 per cent. and absent in 2.8 per cent.

This table of statistics will show that the majority of the cases treated in this hospital are advanced cases of pulmonary tuberculosis, but it must be remembered that *every case treated* at this hospital is admitted on his first application for medical aid and that these physical examinations are made at the time of application. Furthermore, I should like to append a statement that the recorded results of physical examination made by Dr. Lyle confirm so perfectly in every case of death to the autopsy findings that I have the very greatest faith in the entire accuracy of the records of those cases in which no autopsy was made. It is a fact demonstrated by this table that patients apply late for medical aid in pulmonary tuberculosis, and I believe that if we are going to recommend surgical intervention in this disease that it must be applicable to hospital cases as they apply for treatment, and that these statistics will possess surgical value.

THE QUESTION OF EXCISION.

The surgical results obtained by the excision of tubercular foci in any part of the body seem to depend entirely upon the completeness with which the tubercular disease is removed. It must necessarily follow that good results from the excision of a tubercular focus in lung tissue must depend entirely on, 1, the complete excision of the diseased focus; 2, the absence of other foci in other parts of the lungs which will serve as centers of infection quite as dangerous to the individual as that which is excised. The entire tuberculous lesion in the lung must be excised.

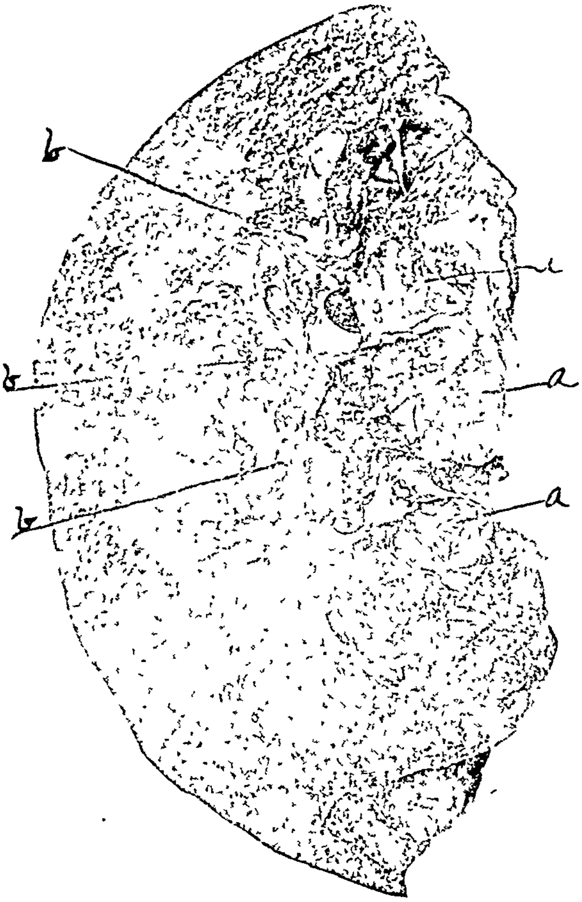

Fig. 5.—Tubercular lung, with extensive involvement of the tracheal, bronchial, and peribronchial lymph nodes, *a*, *b*. Excision impossible.

The operation of excision will manifestly be excluded from consideration in cases showing involvement of all four lobes (74.9 per cent.), in involvement of an upper and lower (2.6 per cent.), in two upper and one lower (8.5 per cent.), one entire side and the opposite apex (1.3 per cent.), and when both upper lobes are involved (3.6 per cent.). Autopsy findings would indicate, furthermore, that when a tuberculous process has invaded an entire upper lobe (2.3 per cent.) there are probably foci elsewhere in the lungs, which will render this lesion likewise inoperable. The sum total of the cases that will be inoperable from the view point of excision is 98 per cent. Apex cases alone, which constitute the remaining 2 per cent. of cases, can be looked upon as cases suitable for excision. This percentage is very small. The percentage would be somewhat raised should cases seen in private practice be arranged in statistical form, yet it would be unwise for us to allow our surgical zeal to obscure our better judgment and cause us to forget that a very large percentage of these cases of apex tuberculosis, as well as many presenting an extensive lung involvement, are cured by climatic, dietetic and hygienic treatment.

It is advised repeatedly by writers on this subject that the operation of excision should be practiced only on those cases presenting isolated circumscribed tubercular involvement of the lung tissue or in isolated cavities. That this condition rarely exists pathologically and that such a diagnosis absolutely can not be made is a fact that has been demonstrated repeatedly in the past and which is demonstrated again by my own specimens and physical examinations. It is impossible that six or sixty miliary tubercles distributed throughout the lower lobe of a lung or located 1 c.m. beyond the line of incision that would be indicated by physical signs could be detected by any known clinical method. An excision of only a portion of a pulmonary tuberculous lesion would be useless if not positively harmful. A tuberculosis confined to one apex alone without tuberculosis in other parts of the lung would certainly be a lucky condition, and we may not operate with a chance of luck alone in our favor. As far as I know the only cases that have thus far been treated by the method of excision are those of Tuffier, Doyen and Lawson. Of these only one was successful, and microscopic examination in this case revealed only an induration of the excised lung tissue.

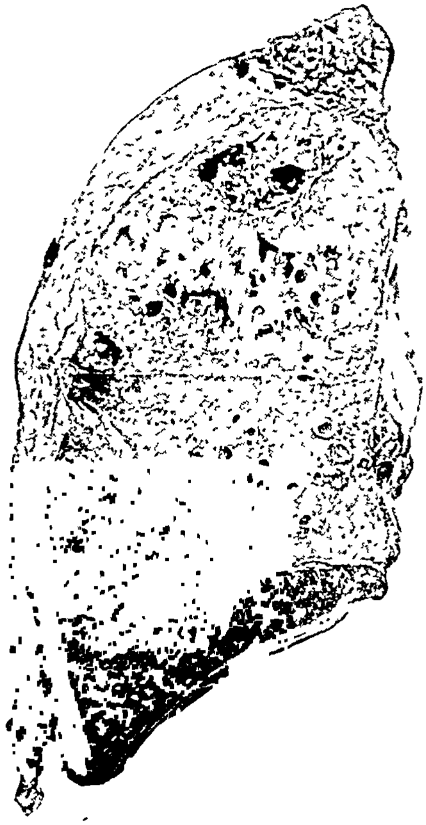

Fig. 6.—Tubercular lung. Entire upper lobe one mass of intercommunicating cavities, middle lobe solidly pneumonic, lower lobe normal.

Excision of tubercular foci in the lung would seem to be both impossible and irrational.

THE DRAINAGE OF CAVITIES.

The second surgical procedure that will claim our attention is the drainage of tubercular cavities. This is practiced, 1, to promote cicatrization; 2, to liberate pent-up pyogenic secretions; 3, to cause cavities left by a healed tuberculosis to cicatrize. A tubercular cavity in the lung is a result of the necrotic element in the tuberculous lesion. Tubercle bacilli lodge in a number of spots in the lung structure, each perhaps separated from another by a varying number of millimeters, and typical miliary tubercles develop. Each tubercle possesses a characteristic globular form about the size of a millet seed; it is made up of an aggregation of epithelioid small round and giant cells; these cells are supported by a stroma, the structure is devoid of blood vessels and the center is usually occupied by caseous material.

Among the many characteristics of a miliary tubercle two are of particular importance in the present study: 1, the absence of blood vessels in its structure; 2, the presence of the toxin forming tubercle bacillus. The entire nutrition of the cells which make up the structure of the tubercle must be carried on by diffusion or by percolation of the body juices from its surface. A poor nutrition, one most marked in the center of the globular mass of cells, is apparent. Added to this burden is the degenerative influence of the toxalbumin of the tubercle bacillus, and the result is invariably a peculiar type of necrosis known as cheesy degeneration. This occurs in the center of the tubercle. The miliary tubercle becomes divided into a crust of tubercular tissue which grows peripherally and in which the bacilli are active and a central caseous mass. Approximated tubercles fuse together by this peripheral growth and form large masses of necrotic cheesy matter. The escape of such a tubercular mass by way of the air passages leaves a ragged hole in the lung tissue. Such cavities have rough, irregular walls made up of cheesy material, which by crumbling away gradually increases the size of the cavity. They contain cheesy matter, detritus, serum, mucus and sometimes pus. Outside of the lining cheesy layer is a thickness of 1 to 4 c.m., which is made up of typical tubercular tissue without blood vessels, a layer of active tubercular extension most active in the portion most remote from the cavity. When nature fights a fairly good battle varying amounts of connective tissue are deposited in this layer, even to the complete arrest of the tubercular process.

To sum up, we have a cavity with a non-vascular, therefore non-regenerative wall of tubercular tissue which has a constant tendency to extend peripherally and a lining of dead tissue containing no germs of the disease. In a simple pyogenic abscess the seat of germ activity is in the lining membrane, the wall of the abscess cavity is filled with budding blood vessels and reparative granulation tissue cells, and all surrounding parts not already necrotic are well supplied with nutrition. Conditions are entirely dissimilar, and it would seem irrational from the start to drain a tubercular cavity simply because the drainage of simple abscesses has given such brilliant results. Drainage alone can accomplish nothing since tubercular cavities usually contain innocuous material, and such drainage can in no way affect the surrounding tubercular tissue. In the next place, there is no tendency to the formation of granulation tissue on the interior of such cavity, and in those cases in which it might perchance occur anatomic conditions are opposed to the contraction of the cavity. The apex of the lung is encased in a firm, unyielding bony box. Added to this, pleuritic adhesions always glue the surface of the lung to the interior of this box and the reparative formation of cicatricial tissue will always pull toward the long surface, thereby artificially enlarging the size of the cavity instead of promoting healing (Gerulanos, Quincke). An incision into such a cavity could not be expected to accomplish much.

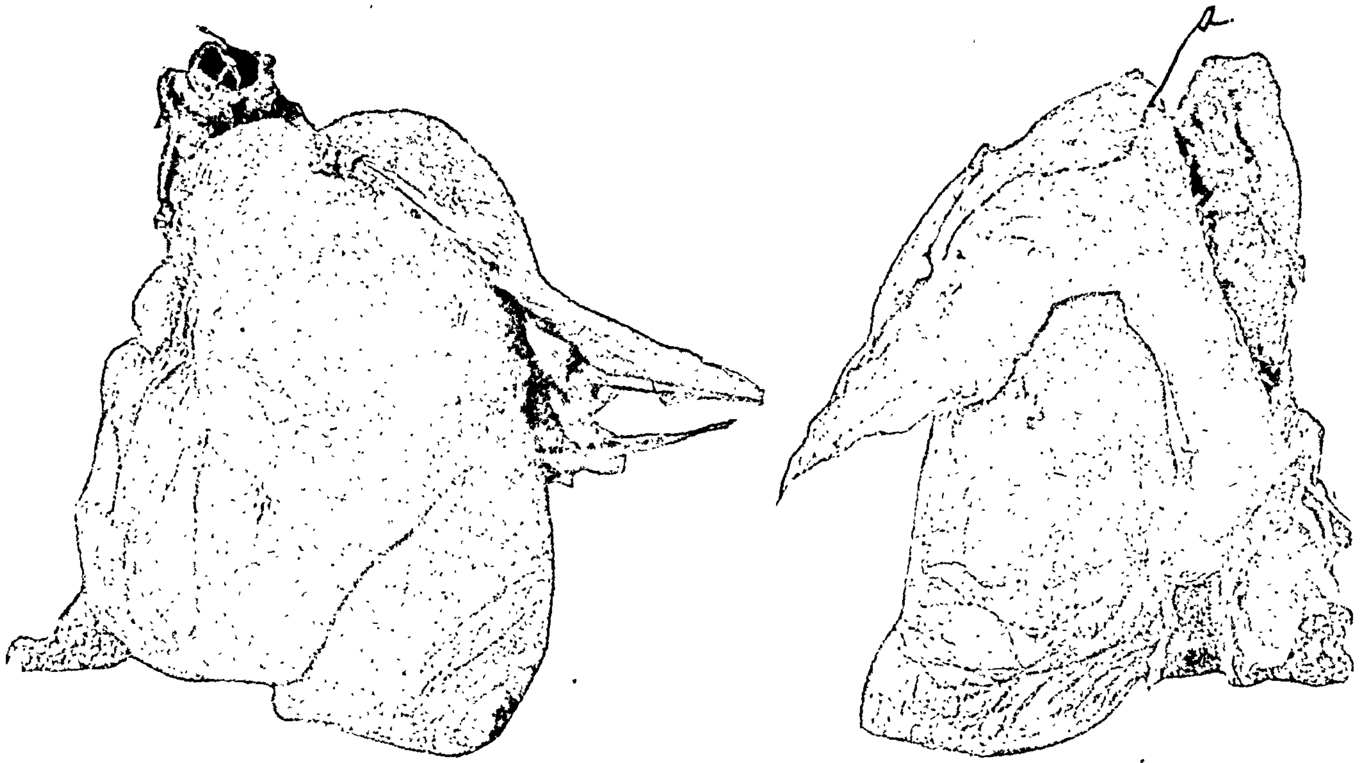

Fig. 7.—Tubercular lung. The greater part of both lungs are solidly tubercular, yet there are no pleuritic adhesions below the extreme apex. Adhesions only above line *a*.

It has been stated that the operative treatment of tuberculous cavities becomes imperative in those cases in which the cavity secretions become retained and infected by the pyogenic germs, and that we are in reality called upon to treat an acute abscess of the lung

(Kummell, Garré, Hearne). Here arises that great subject of lung sepsis in pulmonary tuberculosis which I can not hope to discuss further than to make the following statements regarding this question of retained and infected secretions: 1. The vast majority of lung cavities are located in the apex or in the upper lobe of the lung, sites shown by Quincke to be most favorable to drainage through a bronchus. 2. In the 978 cases studied, Dr. Lyle has not seen a single one in which a cavity has been the seat of such an infection and operation a possible element in the relief of symptoms. 3. The very chemic nature of caseous material (representing as it does a product so low in the scale that it is incapable of further disintegration) makes it an unfavorable if not actually an impossible culture medium for pyogenic germs. 4. Should such infection and decomposition occur often or at all, patients with cavities would certainly have very bad breaths. This is not true. Cavity patients rarely have a stinking breath. 5. Mixed infection in the area of active tubercular inflammation—the active septic pneumonia—in lung tissue not in cavity, is unquestionably the element that plays the part of importance in the septic cases. 6. I present the temperature charts of three patients who have cavities for five, three and two years respectively. These temperature curves are merely samples of all these cases. They are neither high nor septic, and these men have been subjected to all of the vicissitudes of the climatic conditions. 7. The majority of tubercular cases do not run high temperatures at any time. In this series 25.5 per cent. of the cases treated run an average daily and weekly temperature below 99 F., 24 per cent. between 99 and 100 F., 20.7 per cent. between 100 and 101, 14.8 per cent. between 101 and 102, 10.4 per cent. between 102 and 103, while 5.2 per cent. gave an average daily temperature above 103. In general it may be said that in 70 per cent. of cases the temperature was never above 101, and in 85 per cent. of cases never above 102. Furthermore, septic temperatures are not found. 8. The persistence of a sinus is the usual result after drainage, and most of the patients so treated have been more annoyed by this than by the severe symptoms; some have said that death was preferable.

It has been said that those cavities occurring in individuals in which the tuberculosis has become entirely healed can be closed down by operative treatment and the patient cured of his cavity. 1. In the first place such cavities do not usually give these patients great annoyance, a fact abundantly supported by clinical experience and by the autopsy reports of Furbringer and Von Leyden, who have frequently found isolated cavities which had existed for a great many years in the apices of very healthy-looking young people. 2. Should we grant the possibility of effecting a cure in this way, it would be impossible to say just when the tuberculous process has become healed. 3. Operative interference in a cavity that had progressed just short of complete healing has resulted in the development of disseminated miliary tuberculosis and hastened death (Mosler, Kurz). Finally, should it be granted that certain cavities might be opened to operative treatment by drainage there would yet remain the great difficulty of selecting these cases by physical examination. The value of operation on a supposed single cavity would be annulled by the discovery at the time of operation of other smaller cavities which could not have been diagnosed by known physical signs. The Roentgen ray has failed to detect cavities with a degree of accuracy that would give the method diagnostic value.

Sarfert, who has been a zealous advocate of the operative treatment of pulmonary tuberculosis, has been forced to acknowledge that perhaps among hundreds of cases of cavity only a single one may be suitable for operation. Borchert states that the discovery of tubercle bacilli in the sputum is an absolute contraindication to operative procedure, even when the original condition was known to be a chronic simple abscess and the tubercular infection secondary. Körte arrives at similar conclusions. The evidence against the drainage of tubercular cavities would seem to be so overwhelming that I believe the method should not be included within the scope of surgical attack upon the lung.

While the purpose of my paper in reality ends with this attempt to demonstrate that the tubercular lesion is an inoperable one from the view point of excision and the drainage of cavities, I beg your indulgence for the very brief consideration of two other surgical methods of treatment which I believe to possess value.

THE NITROGEN COMPRESSION METHOD.

The treatment of tuberculosis of the lungs by compression with nitrogen, after the method of Murphy, has now been employed by several observers, notably by Lemke, for four years, and the results obtained thus far are certainly very promising. Any method for the treatment of this extremely chronic disease can not be said to be established until a sufficient number of years have elapsed to determine the existence of a permanent cure. The method of nitrogen compression is on trial and seems to be a rational procedure.

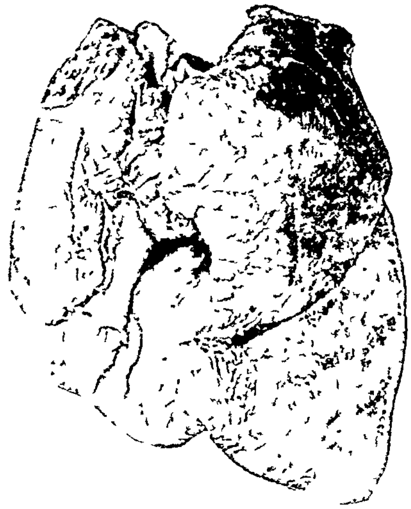

Fig 8.—Tubercular lungs. Right lung had been compressed to spinal column for a long time by a hydro pneumothorax

The good effects of compression, locally, as given by Lemke, are brought about by the limitation of areas of disease already existing by, 1, favoring fibrosis in and about these areas; 2, by occluding the avenues of the dissemination of the virus, and 3, by compressing cavities to enable them, mechanically, to heal. Other effects of compression are due to, 1, rest to the organ as a whole; 2, emptying of secretions; 3, prevention or diminution of absorption of toxic bodies; 4, prevention of secondary infections; 5, the diminished tendency to hemorrhage.

Granted the truth of all these statements and the safety of the operative procedure, the question of the applicability of the method must naturally arise. The application of the method presupposes a pleural cavity, into which the nitrogen gas can be injected in sufficient quantity and diffusion to cause a collapse of the lung. We all know perfectly well that there are many cases in which there is no pleural cavity at all, and that the vast majority of cases of advanced tuberculosis possess adhesions of varying degree. Approximately, 90 per cent. of the autopsy cases examined presented adhesions so extensive that collapse of the lung would have been impossible by the nitrogen method. In others, the lungs might have been collapsed below the level of the fourth or fifth rib, but the entire apex, that portion inclosed in the truly rigid costal box, could not have been influenced much by the pressure. One case would seem to demonstrate that disseminated or irregular adhesions need not be a barrier to the employment of the injection. This specimen was taken from a case of tuberculosis that had suffered a complicating pneumothorax. The old adhesions between the visceral and parietal pleura were so pulled upon by the collapsing force that they were stretched to a band 5 c.m. long. A similar stretching of bands might be expected to occur after nitrogen injection.

Autopsy findings demonstrate another condition of great practical importance, namely, that pleuritic adhesions are usually not coextensive with the pulmonary lesion even when this lesion underlies the parietal pleura. In illustration of this point I would present a photograph (Fig. 7) of a lung in which the entire upper and the greater part of the lower lobe are the seat of tubercular consolidation and extensive destruction. The parietal and visceral pleura are adherent, however, only at the apex, as indicated by the lines front and back.

In the majority of lungs the adhesions are more or less distributed over the surface of the lung. but not usually in the form of complete adhesions which obliterate the pleural cavity. A patch of adhesions will be found here, a free area there.

Sarfert makes the positive statement that autopsies have proven that adhesions and pleural thickening always occurs in chronic cases, at least down to the third rib. Sonnenberg has agreed with this finding. The two apices which I have just presented, the one with a stretched band and the other a very limited area of adhesions, and both in very chronic cases with cavity formation, are merely illustrations of a number of such findings in my experience, and will serve to show that we can rely no more on the possible presence of adhesions than upon signs for the determination of their absence or their distribution.

In seeking to ascertain the value of history and physical examination in determining which cases would be suitable for nitrogen injection this portion of the history records was also reviewed. Only 14.5 per cent. of the cases gave a history of ever having had pleurisy, and in some of these the attack had occurred years before the existing tubercular disease of the lung. Physical examination revealed pleuritic friction sounds in 30 per cent. of the cases. The proportion of cases that do actually suffer from pleuritic adhesions is so high and completely obliterating adhesions have so often been found on autopsy in lungs that gave neither history nor physical evidence of pleurisy during life, that neither element in the examination can be accepted as possessing the slightest value.

Certain selected cases of pulmonary tuberculosis may be rationally treated by nitrogen compression. yet it must be stated, 1, that incipient and apex cases of tuberculosis do not require such treatment; 2, that pleuritic adhesions may entirely obliterate the pleural cavity; 3, that irregularly distributed adhesions may render collapse imperfect and inefficient; 4, that physical examination and the history of pleurisy can not be relied upon in determining the applicability of the method; 5, that autopsy findings demonstrate conclusively that pleuritic adhesions are not coextensive with the tubercular process; 6, that autopsy findings do not establish more than a probability of finding adhesions over a lesion of a certain degree.

The following conclusions have been reached from the present study as having particular bearing on this subject:

1. One lung which had been compressed and totally retracted in a hydropneumothorax for a long time has been studied in its gross and microscopic detail and bears out the anatomic statements of Lemke. It shows fibroid change, no secretions. contracting cavities and a quiescent tubercular process (Figs. 8 and 9).

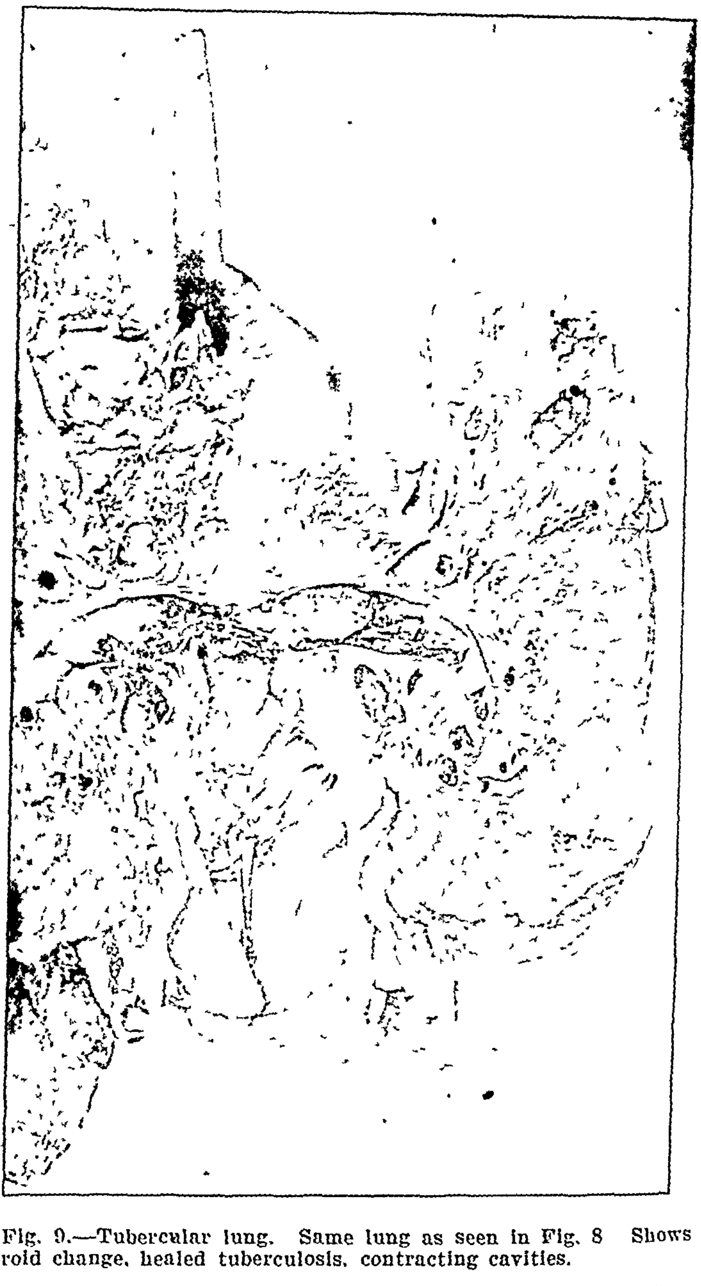

Fig. 9.—Tubercular lung. Same lung as seen in Fig. 8 Shows fibroid change. healed tuberculosis. contracting cavities.

2. A second lung of a similar history and appearance was treated by injecting Kaiserling solution into the trachea. The entirely collapsed lung promptly dilated to the size of a normal healthy lung, despite the fact that it had been collapsed for a long time and that the pleura was greatly thickened.

3. A third case of pneumothorax has furnished Fig. 4. The lung has collapsed and old adhesions at the apex had been so strongly pulled on by the collapsing force that they had been stretched to a length of 5 c.m. Similar stretching might be rationally expected after nitrogen injection.

4. A large percentage of cases have no pleural cavity into which nitrogen gas could be injected.

5. The extent and degree of pleuritic adhesions is extremely variable, is not uniformly present under given pathologic conditions and is rarely coextensive with the tubercular involvement of the lung (Fig. 7).

6. Neither the history of pleurisy nor the physical examination possess the slightest value in determining the presence or absence of pleurisy. In the 978 cases reviewed, only 14.5 per cent. gave a history of pleurisy, and in 30 per cent. pleurisy was diagnosed by physical examination. In every case of autopsy pleuritic adhesions were present and in a high percentage of these cases such did not appear in the history or physical examination.

7. Apex and incipient cases of tuberculosis do not require such treatment by compression.

8. The table presented would show that only about 4 per cent. of all cases would be typical candidates for this form of treatment. The method may be employed, however, in double-sided tuberculosis.

THORACOPLASTY.

The unyielding character of the bony casement of the lung has long been looked on as a potent factor in impeding the healing of cavities. Quincke called attention to the uselessness of making a simple incision into an apex cavity after removing 2 to 6 c.m. of the first rib, and proposed first drainage from the most dependent part of the cavity, then an extra-pleural operation of thoracoplasty. It was proposed to remove the greater part of a great number of ribs over the diseased section of the lung, thus enabling the chest wall to fall in on the lung and the cavities to cicatrize. Turban has performed such an operation on a 21-year-old boy, and this patient was still in good health two and one-half years after the operation. Tubercle bacilli have always been present, however, in the sputum, and the tuberculosis certainly can not be said to be cured. Spengler has operated in a similar manner and reported healing. Franke reported improvement after such an operation, but a sinus persisted and tuberculosis was found after death from an intercurrent disease.

This method of treatment would seem to be based on precisely the same sound principles as the nitrogen method of Murphy, but is, of course, a very extensive operative procedure. It would, therefore, be irrational to use this method when the safe method of nitrogen-gas compression is available, but it seems to me that in those cases of one-sided pulmonary tuberculosis to which the nitrogen compression is impossible of application, this would be a rational method of treatment when climatic and dietetic measures have failed to arrest the progress of the disease.

The arguments to be advanced against such an operation are:

1. The severity of this operative procedure which to be efficient must remove large sections of a number of ribs. This fact alone will prevent a general use of the method.

2. It will always be done in patients much reduced in vitality. Among the 978 patients whose histories were consulted, 82.6 per cent. presented marked emaciation, 14.6 per cent. slight emaciation and 2.8 per cent. no emaciation. This will give a high mortality in the cases operated on and cause us to withhold operative treatment in a high percentage.

3. Animal experiments which I have conducted in dogs have demonstrated that while such extensive resection of ribs enables the chest wall to fall in satisfactorily, it does not secure the complete rest to the lung that will be given by the nitrogen method. In these dogs the chest wall on the side of resection moved in and out with a considerable excursion and the lung certainly filled to a limited extent with each inspiratory act.

4. Climatic treatment renders a fair percentage of cures among the class of cases that would be considered suitable for this operation.

5. The table presented for the demonstration of the distribution of the lesion shows only 2.6 per cent. of all cases to be confined to one side alone, and 1 per cent. in which one entire side and the opposite apex were involved. The percentage of cases primarily candidates for this operation will therefore be exceedingly small, and this small percentage will be still further lessened by considerations already given.

SUMMARY.

The points to which it has been my desire to call attention are:

1. The excision of pulmonary tubercular disease.
2. The drainage of tubercular cavities.
3. The nitrogen compression method of Murphy.

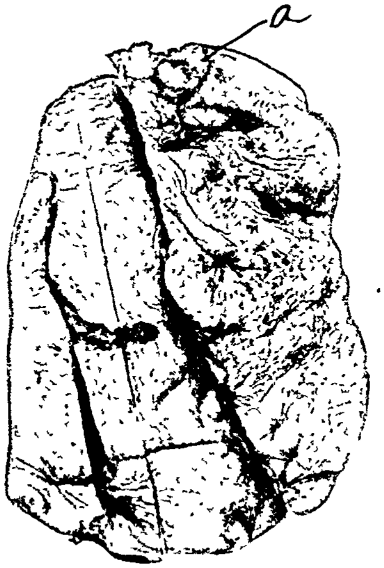

Fig 10.—Healed tubercular focus at the apex (*a*). A counterpart of the case of Tuffier which was successful.

4. The treatment of tuberculosis by extensive thoracoplasty.

The conclusions that will be drawn from the paper are:

1. The excision of the pulmonary lesion is, in the vast majority of cases, both impossible and irrational.

2. The incision and drainage of tuberculous cavities in the lung does not seem to be a justifiable operation.

3. The nitrogen compression method of Murphy is a rational procedure in a limited number of selected cases, its application is safe, the effect on the tubercular lung seems favorable and the reported results are encouraging.

4. Thoracoplasty, while based on the same sound principles that give value to the nitrogen method, is an extensive operative procedure involving great risk to life, and furnishes slight promise of improving the percentage of cures obtained by climatic treatment.

DISCUSSION

ON THE PAPERS OF DRS. WILLARD, M'RAE AND WHITACRE.

Dr. Oliver C. Smith, Hartford, Conn.—I have operated on and published the results of three cases of pulmonary abscess, two of which followed pneumonia, the third followed buccal abscess and was exceedingly severe. The highly infectious pus found its way into the lung tissue by inspiration. The patient grew rapidly worse, was harassed by violent and prolonged paroxysms of coughing accompanied by profuse, offensive and purulent expectoration. I believe this character of cough is highly diagnostic of pulmonary abscess. The patient ran a very high temperature, becoming more and more aseptic and exhausted. It became apparent that he could not live unless a radical procedure was resorted to. Chloroform was administered, two ribs resected and the lung explored. The pulmonary and costal layers of pleura were adherent. The index finger was introduced deeply into the lung; the abscess cavity discovered. A small amount of pus only appeared at the time, but profuse drainage immediately ensued. The patient bore the operation well, and although the temperature ran a septic course several days, he eventually made a complete recovery. I believe the operation of pneumotomy for pulmonary abscess is a life-saving performance and one that has been neglected. The general practitioner frequently fails to make an early diagnosis and valuable time is lost. As to operating on tubercular cavities it is doubtless correct that the field is a very limited one.

Dr. W. J. Mayo, Rochester, Minn.—In reference to securing suitable space to work in, I think we should resect portions of at least two ribs, and if on opening the abscess cavity the drainage is not free, resect still more, as proper drainage is the most important element. In reference to adhesions, it has been our experience that frequently none exist, and the lung looks comparatively healthy at the point at which the pleura is exposed. To secure adhesions we have found the most suitable way was to pack wet pieces of gauze directly onto the parietal pleura and lung, tying them down loosely with catgut sutures. In this way you secure a window through which the lung can be opened at once, if necessary. By these pieces of gauze the lung will be held closely to the desired point. In reference to the cavities one will frequently put a finger in and find bands running across the cavity, which one should be very cautious about breaking. They are the remains of bronchi and sometimes contain a blood vessel. I once broke one and had a tremendous hemorrhage, which was finally controlled by forceps and gauze packing.

Dr. Richard H. Gibbons, Scranton, Pa.—The experiments on animals are very different from the experience we get in traumatic injury of the lung, of which we have many cases in the anthracite coal regions involving the lung structure. We do not get the sudden deaths as often as the experiments on animals would suggest. I have seen many cases in the mining regions where the lung was perforated, but immediate death did not take place, and I have seen them where they would get general emphysema after which the symptoms would subside, although pneumonia or infection might often in the end result in death. If we open up the chest thoroughly we do not run as much risk as in making a small opening. I have taken coal from the pleural cavity and the lung repeatedly. I will not say that my patients all got well, but I will report a case which shows that perforation of the lung is not necessarily followed by death. In this case I did a very large resection of the ribs and attempted Estlander's operation. The cavity was an old one within the pleura, and the late Dr. DeCosta, who had seen the case with me, recommended non-interference. The late Dr. Pepper and Dr. Deaver also saw the case, and they recommended that I should pursue the course that I had proposed. With Deaver's assistance I operated and the man did well. The cavity, at first large, became narrow and very tortuous. I intrusted the packing to one of my assistants. He cut the gauze off squarely—gauze for packing should be torn lengthwise—as he opened the package, and one day after packing the wound he sent for me hurriedly owing to the patient having been seized by marked symptoms of suffocation. The symptoms suggested perforation of the lung, caused by forcing the packing outside of the tract and into the lung tissue, the first stage of so-called lobular pneumonia being established and recognized when I arrived. This patient afterward developed violent coughing spells and repeatedly *expectorated* large fragments of the gauze used in packing during these choking spells. One of the pieces of gauze coughed up was seven inches in length. The gauze being so thoroughly prepared was the only thing that saved the man's life and he has remained perfectly well, now seven years afterward.

Dr. Dudley P. Allen, Cleveland—In reaching the lung when there are no adhesions holding it to the chest wall I have found great aid in bringing the patient to the edge of the table and rolling him over so that the opening in the chest wall is at the most dependent point. With a patient in this position the weight of the tissues in the thorax by gravity tends to draw them toward the side which has been opened. This position greatly facilitates respiration, whereas if the patient lies with the operated side upward the weight of the pulmonary tissues tend toward the unaffected side increasing the difficulty of respiration. When the patient is turned as has been said, with the operated side in a dependent position, the weight of the pulmonary tissues brings the lung against the finger, and it is much more easy to palpate an extensive portion of the lung than it is in any other position. I mention this maneuver in connection with this discussion since anything which facilitates operations upon the lung is of value, recognizing the operation as we do as among those which are beset with considerable difficulty and danger.

Dr. D. W. Crouse, Waterloo, Iowa—I have an engineer under my care who had a two-inch square scantling run into his chest and passing out through the back. The case was not under my care for weeks, and for many days came very near dying. The scantling was pulled out, and a nail, which was in the scantling, tore the parts very badly. It is nearly a year since he was hurt, and I would like to know how to close the sinus that remains. The opening was clear through the body, and by using an injection in the wound in front I can still get a few drops of fluid out of the back. The bronchi seem to be still open, as the man can tell the nature of the wash I am using. The tube I employ is probably from one and one-half to two inches long, and, as there is still some discharge, we keep this tube in in order to keep it open. This case is not exactly germane to the subject of the paper, except in so far as it shows a very serious injury to the lung and the patient recovering from the same.

Dr. A. H. Ferguson, Chicago—Allow me to report a case of tubercular consolidation of a portion of the right lung successfully treated with iodoform introduced into the substance of the lung. It was in a young colored school teacher who presented himself at the Post-Graduate Hospital three years ago complaining of a large fluctuating abscess situated beneath his right pectoralis major muscle. On laying it open and thoroughly removing all diseased tissue with knife and scissors, the third and fourth ribs were found to be involved superficially to the extent of about an inch. Two weeks later consolidation of the middle lobe of the right lung was detected which had recently developed. He had pain, fever and rapid respiration. It was thought to be an abscess. On removing a section of the second and third ribs and passing my finger through the incised pleura above the consolidation, I could feel the upper portion of the lung to be apparently normal and found that the consolidation extended clear across the whole lung, making a complete diaphragm in the chest wall. The exploratory incision in the pleura was now closed and the consolidated area attacked through a lower incision which I extended down to the lung exposing a couple of inches of the solid mass. A large trocar and cannula was carefully inserted into it to the extent of about four inches, but no pus was found. A section of the lung tissue was then removed for microscopic examination, and a dram of iodoform left in the deeper recesses of the explored lung. Professor Klebs declared the specimen to be tubercular pneumonitis. The case then was treated as follows: Through a large cannula introduced with a trocar, a dram of iodoform was deposited into different parts of the consolidated mass twice a week for three months, at the end of which time all consolidation was gone and vesicular murmur returned into that portion of the lung that had been diseased. A late report finds that the case is apparently cured.

Dr. J. C. Oliver, Cincinnati—Dr. Whitacre's paper is certainly a very important and timely one because it supplies the final link in the chain of reasoning in regard to the surgery of the lung. It is particularly important because of the light it throws on tuberculous affections of these organs. This paper shows that it is possible to do a certain amount of surgery on the lung. In other words, there can be no doubt that from a purely surgical standpoint intervention is a feasible surgical possibility. But, basing his report on nearly a thousand cases of tuberculosis of the lung in which postmortem examinations were made, he comes to the conclusion that the proportion in which surgery could be of any possible benefit to the patient is extremely small, less than one per cent.

From these observations and statistics one may logically arrive at the conclusion that while surgical procedures are possible, they are not wise because of the very small proportion of cases in which any benefit can accrue to the patient. It seems demonstrated, therefore, that the surgery of pulmonary tuberculosis will be limited to a very small field and that the present attempts to invade these organs will not be capable of establishing these procedures on a sound surgical basis.

Dr. Jacob Frank, Chicago—I remember one case that did not get well where there were present periodical spells of coughing pus. I decided I would operate on the child just before coughing up one of these masses of pus, and accordingly the ribs were resected, but just as I was about to enter the pleura the child, by a vomit-cough effort, expelled the pus. Immediately the dulness on percussion disappeared. Thrusting the needle in every direction twenty or thirty times, failed to get any pus whatever. Later I became bolder and used my finger, but found no pus. It will not always be as easy to operate on the lung containing pus where the cavity is not rigid and firm, and I can see how easy it would be to go into the lung and open up such a case without finding it. The abscess cavity in the lung collapsed is quite a different proposition for the surgeon from one where the cavity is always full or partially full of pus and the walls through adhesions are well fixed and firm. It is just this latter form of abscesses that become a very simple procedure to open and evacuate, and I dare say most of the successful cases published are of this kind.

Dr. McRae, in closing—In collecting these cases I purposely excluded not only the tubercular and localized pleurisy cases, but also gangrene and septic pneumonias, only including abscess following lobar pneumonia. The remarks of Drs. Mayo and Frank are very important. I observe Dr. Frank did not establish adhesions first. Personally, I have been very much interested in studying these cases. Dr. Frank made a good point in emphasizing the difficulty of locating abscess cavities where there are no adhesions of pleuræ.

Dr. Whitacre, in closing—I would like to mention two points in connection with the paper on abscess of the lung. I believe that it is now becoming a well-recognized fact that a high percentage of cases of empyema have their origin in a small abscess of the lung which is located just beneath the pleura. These abscesses break through into the pleural cavity, produce an empyema and the case is so classed without reference to the primary seat of the suppurative focus. I have in the Pathologic Exhibit a specimen which shows such an abscess beautifully. I have seen two cases of empyema in which a bronchial fistula was present immediately after operation for the relief of the pleural collection and in which abscess of the lung undoubtedly preceded the empyema. The second point I wish to make is that cases of abscess of the lung recover under medical treatment and that surgical procedure should not be instituted until it is clearly demonstrated by many weeks of treatment that no progress is being made. During the past winter I have had two cases of abscess of the lung, each with one pint capacity, which I hoped to be able to operate on, but they both recovered perfectly without operation.

The case of tuberculosis, which Dr. Ferguson has referred to in his discussion of my paper, has interested me very much in the review of the literature on this subject. I am impressed, however, that this favorable result was a very happy chance, and that it should not be taken as an argument in favor of operating on tubercular lungs. I have referred to a specimen in my collection, which is to be found in the Pathologic Exhibit, in which there was, as nearly as it is possible to determine by physical examination, a circumscribed mass of tuberculosis of the same nature and in precisely the same location. On autopsy this mass was found, as located by physical examination, and all other parts of the lung were found to be entirely free from tubercular deposit except for one mass the size of an English walnut, which was found in the base of the lung at a point most remote from the chest wall and entirely beyond the possibility of detection by physical examination. Operation on what appeared to be the sole focus would have been useless.

Tuffier's case is frequently referred to as a successful case of excision. The complete report of the case is not made, however, and it is not always stated that this was a healed tuberculosis, that microscopic examination revealed only individual lung tissue. I do not believe that this case has any right to consideration as a successful one.

While it has now been definitely established that adhesions are not indispensable to operative attack on the lung, I have included this point in my investigation of case reports. I find, as was stated in the paper, that adhesions are by no means co-extensive with the tubercular process, and that neither our pathologic knowledge nor our present methods of physical examination will render information of value in determining either their presence or absence.

Removing Picric Acid Stains.—Brynk, in *Bull. Phar.*, recommends rubbing the skin or fabric with a solution of 10 parts of sodium benzoate and 40 parts of boric acid in 1000 parts of water.

THE DIAGNOSTIC IMPORTANCE OF KERATITIS PUNCTATA INTERNA (DESCEMETITIS).*

HARRY FRIEDENWALD, A.B., M.D.
BALTIMORE.

The term keratitis punctata is applied to several very different conditions. We must distinguish between the true punctate inflammations, the keratitis punctata profunda, the keratitis punctata superficialis, etc., and that form which consists of deposits on the inner surface of the cornea. If we retain the term for this form we should define it as "keratitis punctata interna." This condition is also known by the name of descemetitis, and, while there are objections to this term, it is less liable to produce confusion, and for this reason and for the sake of brevity we shall use it in this paper.

In a paper published in the Archives of Ophthalmology[1] six years ago, I brought evidence to show that descemetitis occurs in every case of iritis. I divided the descemetitis into two forms—the coarse, which can be seen with the naked eye, and the fine, which is detected by means of strong convex lenses behind the ophthalmoscope. The former is occasional, the latter constant. It is the coarse variety only to which most writers refer under the term of descemetitis.

Concerning the position which these deposits take, little need be said. The coarser opacities are found chiefly or entirely in the lower half of the cornea, frequently arranged in the well-known triangular form. In rare cases the entire inner surface is covered. The fine opacities are also most abundant in the lower half, but frequently cover the upper half as well. Exceptional cases occur in which the spots cover an area more or less central. The largest spots rarely exceed one mm. in diameter and are usually round. In very rare cases they assume irregular forms and become much larger. In a case of tubercular iritis which recently came under my observation, they were so large and so much resembled the miliary tubercles on the surface of the iris that I assumed that they were likewise of a tubercular nature.

In order to learn the facts as to the occurrence of descemetitis in various diseases of the eye, I have carefully reviewed my case—histories both hospital and private for the past twelve years. This paper is a summary of these cases, together with the conclusions to which they lead. Assuming that my statement that descemetitis occurs in every case of iritis is accepted by all who have given this subject any study, I shall refrain from citing in this paper several hundred cases in which this condition depended upon iritis. I may add that observations since the publication of my former paper have corroborated the views then expressed. I have also omitted all cases of diffuse keratitis. At the same time I desire to state that I have never found descemetitis absent during the active period of this disease. Finally, before taking up the individual cases and conditions, I desire to state that the following notes are taken from my histories, many of which are unsatisfactory because incomplete, or because of the failure of patients to return.

A. CASES OF DESCEMETITIS WITHOUT OTHER DISEASE.

Case 1.—Mr. G., aged 30, was seen July 3, 1900. The sight of the left eye was blurred and the eye had been painful for two weeks. The pupil responded promptly to atropia. There was marked descemetitis. Atropin was ordered. Two days later there was no evidence of iritis, and the fundus appeared normal.

Case 2.—Miss R., white, aged 29, complained of her eye for ten days. There was descemetitis without any evidence of incipient iritis. No note of fundus. Patient seen once.

Case 3.—Mr. M. C. G. complained of the sight of bad vision in the left eye for one week. The pupil dilated freely under atropia. There was marked descemetitis occupying a small portion of the cornea just below the center. The image of the fundus was blurred, but appeared normal. Patient was seen but once.

In none of these cases were there notes of other evidences of uveitis. It is to be mentioned that in none is there a note as to the presence or absence of vitreous opacities. All of these cases were dispensary patients and seen only once or twice.

We may here add two cases in which the opacity of the cornea was so great as to prevent examination with the ophthalmoscope.

Case 4.—Mrs. H., aged 29; she had had recurrent inflammation of the right eye since childhood. The last attack began one week before she was seen by me. There was a diffuse opacity covering the lower half of the cornea (old diffuse keratitis?) with a few fine calcareous deposits, and distinct descemetitis. The iris was normal. Diagnosis: Old uveitis with recurrence.

Case 5.—Mr. R. E. C., aged 38, has been under treatment since May 20, 1902. There was dimness of vision for three weeks before he came under treatment. At first there was pain, but this had disappeared. There was extensive descemetitis covering the entire cornea. The pupil dilates without any synechiæ. There is sensitiveness to pressure in the upper inner portion over the ciliary body. No ophthalmoscopic reflex. Fingers are seen at four feet. He denies lues; the urine is normal. In this case the descemetitis is of a peculiar form. Besides the many coarse and fine opacities usually seen, there are deposits arranged somewhat in the form of a circle around the central part. These deposits are very large and irregular and are confluent. (See Fig. 2.) It is probable that there is extensive uveitis, but the opacity at present prevents examination of the fundus.

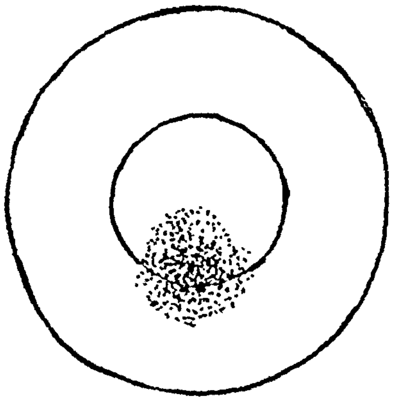

Fig. 1.—Case 3.

B. DESCEMETITIS WITH CYCLITIS.

Case 6.—Mrs. B., aged 31, was seen Dec. 22, 1897, complaining of a mist before the left eye for several days. The pupil dilated ad maximum under a mydriatic; the vitreous was clear, the fundus normal, but there was extensive descemetitis. Under iodid of potash the condition gradually improved, and in the following May the cornea was almost clear. In September, 1898, a few small permanent opacities resulting from the descemetitis were found. But in October she returned with descemetitis in both eyes and distinct synechiæ. At no time was there any pain. Iodid of potash was again ordered and atropia used and the condition rapidly improved.

Case 7.—Mr. C., aged 49, was seen June 19, 1900. Six months previously he had had severe iritis in the right eye and an iridectomy had been done. He now complains of pain in the left eye. There are no synechiæ, but a coarse descemetitis covers the lower half of the cornea. There is no note of the fundus and the patient was not seen again.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott.

[1] Vol. xxv, 1896, p. 191.

In the last case but one (Case 6) we found descemetitis in the left eye without other evidence, at the time, of uveitis: ten months later there was recurrence in both eyes with distinct though slight iritis. There is little doubt but that the chief trouble here was cyclitis with slight involvement of the iris during the second attack. In Case 7 the patient had recently passed through a severe iritis in one eye before the other eye became affected with the descemetitis but without synechiæ. The diagnosis of cyclitis is most probably correct.

Case 8.—Mr. G., aged 28, applied for treatment Jan. 8, 1891; he had had great pain in the left eye for one week. The examination showed that the pupil was responsive to light; there were no synechiæ. The color of the iris was somewhat darker than in the other eye; a few blood vessels could be seen on its surface. The circumcorneal congestion was marked, but the ciliary sensitiveness was not great. The cornea was studded with the finest deposits on Descemet's membrane. Atropia was instilled, and on the following day a second careful examination showed the same corneal deposits and likewise striæ in the cornea. The striæ persisted for a number of days during the intense stage of the inflammation; toward the end of January the cornea became clearer, the congestion of the eyeball diminished. February 4 the eyeball was almost white, but the corneal deposits, though fine, were still to be found and there were likewise some fine deposits on the anterior capsule of the lens. The condition then rapidly improved; synechiæ did not develop in this case and the affection of the iris was very slight in comparison with the severity of the symptoms. The diagnosis was acute cyclitis with slight involvement of the iris.

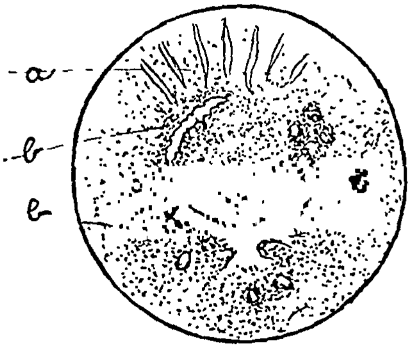

Fig. 2—Case 5. *a*, Striate keratitis; *b*, large confluent deposits.

Case 9.—Mrs. F., a myope, was seen frequently from Aug. 7 to Oct. 7, 1897. The patient had complained for two weeks before she was first seen. The eyeball was at first congested. There was little pain. There was typical gross descemetitis, triangular in shape in the right eye. The media were too cloudy to permit of ophthalmoscopic examination. There was one small synechia. The condition gradually became clearer and finally but a few brown deposits were found on the cornea. The patient was seen two years later, the fundus found normal and the media clear. In this case there was without doubt intense cyclitis, with slight involvement of the iris.

Case 10.—George H., aged 25, was seen early in August, 1896, complaining that his eye had been cloudy for four days. There was peculiar descemetitis, almost circular, which did not reach the lower limbus (Fig. 3). There were no changes in the fundus nor in the iris. The patient was seen frequently and carefully examined. When after four weeks the corneal opacity had cleared up (leaving a little spot of permanent opacity in its center), fine dust-like opacities were found in enormous quantities in the anterior portion of the vitreous, and there was one larger opacity. Diagnosis: cyclitis.

In this case there was at no time any pain. The eyeball became but slightly congested. The extent of the descemetitis became somewhat enlarged after it was first seen, but it never lost the round shape. The presence of the vitreous opacities proves that the deeper uveal structures were involved.

Case 11.—Miss F., aged 39, with excessive myopia, choroidal atrophy and poor vision (—15 Ds. 6/60), was operated on the left eye in October, 1900, for the relief of the myopia. Discission was performed twice and in December the lens substance was removed through a linear incision. Her vision improved so much that in October, 1901, she came for operation on the right eye. In this eye the removal of the clear lens, without iridectomy, was performed Oct. 22, 1901. Barring slight incarceration of the iris, and one synechia, there was excellent recovery, but some cortical matter was left. This rapidly absorbed and excellent vision was obtained through a central opening. On December 11 the patient was again seen. The eyeball had been somewhat congested and the cornea was studded with a number of large spots. Atropia was ordered. In two weeks the eye was much clearer and on February 14, when the patient was again seen, no fundus change could be found, the cornea and other media were clear, and vision after correcting the astigmatism was almost 6/12.

The appearance of the descemetitis in this case almost two months after the operation, when the pupil was sufficiently clear to allow of ophthalmoscopic examination, makes the diagnosis of cyclitis probable. This was without doubt due to incarceration of the iris and the presence of old iritic synechiæ.

Case 12.—Mr. T., aged 27, was seen June 24, 1893. Both eyes were very myopic. The sight of the left eye had become very much reduced (2/200), and the field was much limited. The left cornea was studded with large and fine deposits and the vitreous filled with fine and coarse opacities. The corneal opacities rapidly disappeared, but the vitreous opacities lasted for a long time. The fundus was then found normal.

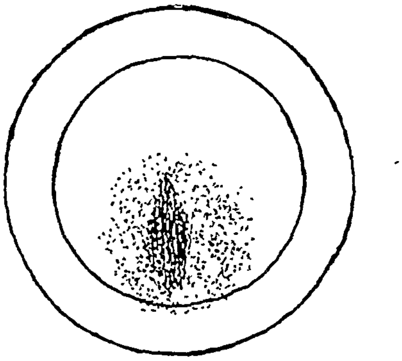

Fig. 3.—Case 10.

Case 13.—Frank R., aged 28, was seen once in January, 1894. He had been suffering with impaired vision in the right eye for two years; during the past year there had been great improvement while under the treatment of another physician. No cause could be assigned. Vision was now almost 5/7, but the cornea contained scattered deposits and the vitreous numerous opacities. The iris was normal and no fundus change could be found. There was marked asthenopia in near work.

Case 14.—Wm. B., aged 23, was seen Sept. 5, 1894. The patient had suffered from chronic rheumatism. The right eye had been struck nine years previously and was frequently painful since that time. There was great asthenopia and spasm of the accommodation. On September 13 slight hazy spots were found in the right lens and a few opacities in the vitreous. The patient was seen often and there was apparently frequent change in the refraction. Dec. 14, 1896, he appeared with numerous deposits on Descemet's membrane. February, 1897, the eye became painful, the vitreous showed many opacities and there were some fine mottled opacities in the cornea. The condition increased at first, then cleared up, and in June the cornea was again almost transparent. But at this time the right eye began as the left had in February, and went through the same changes. In March, 1898, there were extensive deposits on Descemet's membrane in both eyes as well as vitreous opacities. The condition gradually improved. No fundus changes were observed.

Case 15.—Miss M. A. B., aged 26, was seen Nov. 9, 1891. The lower half of the cornea was studded with fine descemetitis. The pupil dilated *ad maximum* under atropia and there was no evidence of iritis. Even with the dilated pupil, only a dull reflex could be obtained in all directions, but no distinct image. There were large vitreous opacities. The patient stated that the condition had been worse, but was now improving. Fingers were counted at five feet. Patient was not seen subsequently.

Case 16.—Miss D., aged 33, was first seen April 9, 1901. She complained of blurred vision in the right eye for the past three months and had long suffered from severe headaches. There was marked descemetitis, and the vitreous was filled with fine and coarse opacities. V-20/200. There was no sign of iritis, and careful examinations of the fundus (then and since) have failed to reveal anything abnormal. The visual field was perfect. She was examined for disease of the heart, kidneys and blood, with negative result. There was no evidence of lues. She was given red iodid of mercury alternating with iodid of potassium.

The patient has been seen frequently. This condition has fluctuated, but has not at any time disappeared. At the last examination on May 14, 1902, V-20/100. The right cornea is still studded with fine deposits. The lens is clear. The vitreous contains fine and coarse opacities. The fundus is normal and the field of vision for white and red is perfect. The left eye has not at any time shown any evidence of disease. Diagnosis: chronic cyclitis.

In the last series of cases there was sufficient evidence in the extensive vitreous opacities of deep uveitis, but as the fundus showed no abnormalities and the iris was unaffected, we place the lesion in the ciliary portion. The three cases that follow give still further evidence of uveitis in the development of cataract in young and otherwise healthy persons.

C. DESCEMETITIS WITH DEVELOPMENT OF CATARACT IN YOUNG PERSONS.

Case 17.—Mrs. N., aged 32, was first seen Jan. 23, 1898. She complained of having had "spots before her sight" for some time, and that in the past few weeks the condition had become much worse. In the right eye there were numerous dust-like, vitreous opacities, and the lens likewise contained similar opacities. The optic disc and retina appeared normal. In the left eye there was rapidly developing cataract, and the fundus could not be examined. Both corneæ were studded with fine and coarse deposits. Close examination did not reveal any choroidal lesions even in the periphery. Vision in the right eye was 6/8, 6/6 partly with plus 1.5 Ds; the left eye distinguished fingers at four feet. The field of vision of both eyes (for white and colors), was approximately normal. The patient was carefully examined and was found healthy in every respect (heart, blood and urine). She was given iodid of potash in small doses, and later the red iodid of mercury. In March of the same year the vitreous of the right eye had become clearer, but there was still descemetitis in both eyes. The cataract of the left eye had increased. The descemetitis was discerned as late as April. In August I could find no deposits on the corneæ and the right vitreous was almost perfectly clear. The opacities in the right lens had not made any advance. There was at no time pain or other active signs of inflammation. The patient left the city and was not seen until December, 1899. The cataract in the left eye in the meantime became sufficiently mature to permit of an operation, which was performed Jan. 1, 1900. A small iridectomy was made and an excellent result was obtained. The patient was last seen in April, 1902. The vision of the left eye is perfect and a careful examination of the fundus failed to reveal any changes. The condition of the right eye is practically unchanged.

Case 18.—Miss F. D., aged 10, an apparently healthy and well-developed girl, was first seen Feb. 3, 1898. She had complained for a few days of blurred vision in the right eye. The right vitreous was filled with fine opacities. There was marked descemetitis. No choroidal lesion could be found. The left eye was perfectly normal. Vision was almost perfect. Toward the end of the month the cornea became clearer. The patient was seen frequently and on March 14, I observed a number of small opacities near the posterior surface of the lens. They gave the picture of minute bubbles. Vision remained about the same and the field of vision was perfect. The corneal opacities were observed from time to time as late as November, 1899, but in April, 1900, the cornea was perfectly clear. In the meantime the lenticular opacities had gradually increased and formed a more or less circumscribed cataract in the outer, upper portion of the posterior cortical layer. In October, 1901, there was a recurrence of marked descemetitis and the opacity of the lens had increased somewhat. She was last examined in November, 1901, and numerous deposits were still found on Descemet's membrane. The opacity of the lens had not increased and her vision is still good.

Case 19.—Mrs. G., aged 27, was seen on May 1, 1902. She had been forced for the past few years to sew to an excessive amount and had found that the sight of the left eye had been failing. She was otherwise in good health, but had lost in weight, which was due, as she thought, to overwork and worry. The right eye was found to be perfectly normal (plus 1.75 V-6/5); left eye showed extensive descemetitis and opacities in the form of small globules throughout the posterior portion of the lens. The vitreous could not be examined, but a sufficiently clear picture of the fundus was obtained to determine that the optic disc was normal and that there were a few small, pale, pink and sharply circumscribed spots in the periphery of the choroid. The field of vision was slightly contracted.

The development of the cataract in these cases is the expression of marked nutritive disturbance and can only be ascribed to uveitis, for general constitutional disease was definitely excluded. On the other hand, there were in all the cases abundant opacities of the vitreous which likewise indicated uveitis.

D. DESCEMETITIS ASSOCIATED WITH GLAUCOMA.

Case 20.—W. T., aged 42, was seen July 24, 1900. There was a deep glaucomatous excavation with atrophy of both papillæ. The left fundus appeared blurred because of enormous vitreous opacities and gross descemetitis arranged in triangular form. Vision, right eye, 10/200, left eye, perception of light eccentric.

Case 21.—Mrs. F., aged 28, was seen April 10, 1902. Seven years before she had had trouble with the left eye, at first in the form of spots and after a time vision was entirely lost. The eye was never painful. She now suffered slight discomfort. T. plus ½ or 1. The pupil was not dilated. The cornea was studded with large deposits in the lower half, but the entire surface contained finer deposits. V=0. In order to exclude any malignant growth by ophthalmoscopic examination, a mydriatic was used in spite of the high tension. There was a cataractous opacity in the central posterior portion, but with the dilated pupil a dim image of the disc was seen. By parallactic movements the excavation was distinctly made out. No other fundus changes could be made out, but there were abundant vitreous opacities. The right eye was perfectly normal.

In the last two cases the evidence of uveitis are vitreous opacities, glaucoma and in the one cataract. The ophthalmoscopic image was not sufficiently distinct to exclude choroiditis with certainty.

E. DECEMETITIS WITH ACUTE CIRCUMSCRIBED EXUDATIVE CHOROIDITIS.

I have next to report that descemetitis was observed in 31 cases of fresh exudative choroiditis. These cases will not be detailed individually on this occasion. I shall reserve their publication for a separate paper, partly because it would require too much time, but especially because I am desirous of calling attention to many other points of interest in these cases besides descemetitis. This disease, which is observed between the ages of 17 and 50, the average age being 27¼, is characterized by the appearance of white or bluish white circumscribed effusions near the optic disc or the macula, but very frequently in the extreme periphery of the fundus. The size of the effusion may be less than that of the disc or it may be six or eight times as large. The symptoms so far as vision is concerned consist most frequently in the appearance of muscæ with a blurring of central vision, which may be slight or marked, and result in complete loss of central vision when the effusion is in the foveal region. There is rarely any pain. I have examined in all 38 cases of this affection which were more or less recent and, as above stated, 31 showed descemetitis. In four, the patient was seen too late and the deposits had probably disappeared. In one the pupil was too small to make a careful examination, and in only two was there no explanation for their absence. Vitreous opacities were never absent. In many of these cases the corneal deposits disappeared within a few weeks, but the vitreous opacities lasted for a long time. The effusion gradually disappears and leaves an area of atrophy and irregular pigmentation. The disease shows marked tendency to recurrence.

I should like to say a word here as to how these effusions are to be found; the examination of the field of vision is an excellent guide, and has helped me in a number of cases. But I rely chiefly upon watching the ophthalmoscopic reflex in different portions of the fundus and examining with the indirect image whenever a whitish reflex appears.

F. DESCEMETITIS IN SYPHILITIC CHOROIDITIS.

Case 22.—Mr. H. was seen March 4, 1902. The patient had had luetic infection nineteen months before, followed by mucous patches, but without any skin eruption. An iritis in the left eye soon followed. This was rapidly cured. Eight months ago he noticed a scintillation before the left eye and vision dropped slightly. This scintillation has continued ever since and is very annoying. He does not complain of his right eye. In the left eye there are dense vitreous opacities, but the papilla can be made out with a little difficulty; the cornea is studded with descemetitis; there are numerous brown spots on the lens, traces of old iritis. The upper lid droops slightly. In the right eye the fundus appears normal, there are some vitreous opacities and fine descemetitis. Vision of the left eye scarcely 3/45. In the right 6/18. The patient was put on mercurial inunctions and jaborandi. He was last seen May 1. Vision had improved; right eye, 6/15, —0.75 Ds 6/9 almost; left eye 6/30, —0.5 Ds 6/15 partly. The fundus had cleared sufficiently to show a few light pinkish choroidal spots, typical of syphilitic choroiditis.

In this connection I desire to state that in another case under observation at the same time, in which but one eye was involved and the condition never became as bad as in that just described, no corneal deposits were observed.

I wish next to refer briefly to a few cases in which the chief disease appeared to be extra- and not intraocular. At the beginning of this paper I referred to diffuse keratitis. I have observed descemetitis twice in cases of circumscribed keratitis.

G. DESCEMETITIS ASSOCIATED WITH CIRCUMSCRIBED INTERSTITIAL KERATITIS.

Case 23.—Mr. O., aged 25, was seen in April, 1896. There was circumscribed keratitis which at first appeared to be incipient diffuse keratitis, but which did not take this course. There was marked descemetitis. There are no notes as to the fundus.

Case 24.—Mr. E., aged about 30, who was first seen Feb. 15, 1902, complaining of the left eye. He ascribed his trouble to having had a little hot wax fly into the eye, after which the eye had remained red for some time. There was no constitutional disease and lues was denied. When first seen there was slight injection of the eyeball just below the cornea, a small area of sclerotizing keratitis, fine descemetitis and the fundus was normal. He was seen again March 21, the fundus was normal and there were no signs of iritis; a few fine blood vessels had penetrated into the sclerotizing region, and there was still descemetitis. The patient had been seen in consultation with his family physician, who reported on May 1 that the eye had become perfectly normal.

H. DESCEMETITIS ASSOCIATED WITH SCLERITIS.

A second extra-ocular condition with which I have found descemetitis associated is scleritis.

Case 25.—Thomas K., aged 27, had lues for two months, when he was attacked with severe scleritis. The fundus was perfectly normal. A week later there was fine descemetitis with numerous larger deposits. Two weeks after this the scleritis had disappeared (under specific treatment) and the cornea was much clearer.

Case 26.—Mrs. B., aged about 35, had double retrobulbar optic neuritis in April, 1896, from which she recovered with very good vision. In January, 1899, she returned with inflammation of both eyes, which had made its appearance almost immediately after having exposed herself to the cold while menstruating (without any additional covering she hung out her wash on a very cold day). There was well-marked scleritis in both eyes. I left the city soon afterward and did not see her again till June, 1901. She had had the scleritis for a long time, but was now free. At this time there was marked descemetitis, especially in the right eye, without fundus changes.

In neither of the two cases just cited is there any note of uveitis. Scleritis frequently results in uveal involvement, and I am inclined to believe that there was secondary involvement of uveal tract in both of these cases. I have found iritis and old synechiæ in several of my cases of scleritis.

CONDITIONS IN WHICH DESCEMETITIS IS ABSENT.

I have not found descemetitis in any cases of disseminated choroiditis, central choroiditis, senile choroiditis, myopic choroiditis, and, as mentioned above, it was absent in one case of syphilitic choroiditis in which it was carefully looked for, and in several others in my case books. It is absent in hemorrhages of the retina, choroid or vitreous, and I have never seen it in any case of retinitis excepting in syphilitic retinitis (but in this case there was also iritis).

SUMMARY.

Keratitis punctata interna, or descemetitis, is observed in various ocular diseases. It is found in every case of iritis. It is an almost constant sign of exudative choroiditis and is sometimes found in syphilitic choroiditis. It is also observed in cases of acute and of chronic cyclitis. It is found in diffuse and in circumscribed keratitis, in which cases it probably depends upon an underlying uveitis. It is sometimes seen in scleritis; and is then probably due to associated, perhaps secondary, uveitis. When no other signs of uveal disease are noted besides descemetitis, as in the first three cases of our series, it is due to carelessness in the examination.

Excluding the cases of external disease (diffuse and circumscribed keratitis and scleritis) and the great category of iritis, I have been able to report on 53 cases. Even including those earlier ones in which the examinations were not made with the thoroughness of those of later years and including those in which the opacities of the media prevented examination of the fundus, they show that about three-fifths have exudative choroiditis. This ratio is indeed high; I ascribe it to the fact that, convinced for a number of years of the frequency of these cases, I have examined the fundus in many cases for a long time and repeatedly until I found the looked-for lesion. In some the diagnosis was not made until the second visit and after a mydriatic had been used, and in several of those seen in dispensary practice the lesion was not observed by any of those who examined the cases until it had been pointed out to them. Experience has taught me that a large number of these cases pass through the hands of skilled ophthalmologists without discovery of the true lesion. I do not hesitate to say that if my earlier cases had been examined more carefully exudative choroiditis would have appeared relatively still more frequent than has been shown in this paper. It is due to ignorance of these facts and to carelessness in examination that so many cases are still recorded as "serous iritis" and "serous cyclitis." It should be noted that we can examine with the ophthalmoscope only that part of the choroid lying back of the equator, and, at most, with a dilated pupil the equatorial region or a little beyond it.[2] Exudations in the anterior portion of the choroid may therefore be beyond the reach of the ophthalmoscopic examination. Such cases will be grouped with cyclitis.

Do the cases reported throw any light on the nature of the cyclitis with which descemetitis is associated? We know that descemetitis occurs in iritis, in which disease we always have an exudative inflammation. We find descemetitis in choroiditis only when there is exudative inflammation. It is but reasonable to infer on clinical grounds that descemetitis occurs in cyclitis only when there is exudative inflammation. The "serous iritis" and "serous cyclitis" have, therefore, no clinical bases. That they have no pathological basis has been pointed out recently by Bruns.[3] It is to be hoped that these terms will be discarded in the future, and our section would do well to express itself with decision to this effect. One point that I should especially like to impress by my paper is, that in a large proportion of cases ordinarily diagnosed as "serous iritis" and "serous cyclitis" we find exudative choroiditis.

INJURIES OF THE EYE PRODUCTIVE OF DISEASES OF THE UVEAL TRACT.*

HOWARD F. HANSELL, M.D.
PHILADELPHIA.

The accidents to which the eye is exposed are manifold. Notwithstanding its bony environment and its soft and resilient orbital cushion, the prominent and commanding position in the head affords a conspicuous target for flying missiles, and the insufficient protection afforded by the lids and lashes and the practically uninterrupted functional application of the eye during working hours materially contribute to its dangers. The fortunate provision of nature, the endowment of man with two eyes, saves us from blindness should disaster overtake one-half of the visual anatomy, but this very duality multiplies the danger, and, more than that, uncared traumatic inflammation of the one threatens the safety of the other eye.

Apparently insignificant injuries are sometimes followed by the most disastrous results. This ocular inconsistency between cause and effect is to be traced in every instance to either delayed or unwise treatment or to the state of the constitution of the individual at the time the injury is received.

It seems to me useless to spend the time allotted to the reading of this paper, or your time in listening to it, by consideration of the kinds of injuries, such as incisions, punctured wounds, concussion, foreign bodies, etc., or to dwell on the well-known exceedingly complicated anatomy of the uveal tract and the diseases induced by accidents. I prefer, therefore, to confine my remarks to a brief discussion of the constitutional complications and the early and late treatment of injuries of the eye causative of disease of the uveal tract.

The object of the treatment is two-fold, namely, the preservation of useful vision and, in cases in which this result is unobtainable, the saving of the eyeball.

A favorable prognosis depends in large measure, as I have intimated, on a constitution free from inherited or acquired taint and uncorrupted by devitalizing habits.

I wish to direct your attention to the pernicious influence on the course and termination of traumatic inflammation of syphilis, diabetes and tuberculosis. Any one of these affections will render the prognosis uncertain if not actually bad by intensifying the inflammation or changing its character, or developing a tendency to involve adjacent or remote organs.

SYPHILIS.

In *syphilitic patients injuries* to the eye are accompanied by exudation from the iris, ciliary body and choroid that destroys the transparency of the media and tends to alter the normal relation between secretion and excretion, and leads eventually to secondary degeneration. From the iris the exudation is poured into the anterior and posterior chamber and into the tissue of the iris, and from the posterior portion of the uveal tract into the vitreous. The iris becomes adherent on its posterior surface and pupillary border to the lens and the pupil occluded. Precautionary iridectomy is followed by further exudation and by closure of the coloboma, and finally the ball is enucleated to save the pain of secondary glaucoma. In view of this common termination the inception of traumatic iridocyclitis must be energetically combated by the free exhibition of mercury and the iodids, and the earlier this treatment is instituted the more hopeful the outcome. My experience leads me to believe that the most thorough and rapid method is by mercurial inunction or calomel in small and frequently repeated doses, combined with iodid of potassium in rapidly increasing amounts. Salivation and iodism are postponed and the influence of the remedies increased by the simultaneous institution of the sweat treatment by pilocarpin, hot baths and the usual adjuncts. Locally, the frequent use of strong solutions of atropia. hot compresses, leeches and blisters is indicated. The subconjunctival injections of large quantities of weak solutions of mercury bichlorid are reported to have been useful in checking inflammation and preventing suppuration. Their good offices I have witnessed in one striking case. A non-syphilitic boy of 3 was badly wounded by a rusty iron hinge. The cornea was torn through, the iris and probably the lens were prolapsed, and after a few days the ocular contents showed every indication of becoming purulent. Repeated injections of mercuric bichlorid, 1-10,000, under the conjunctiva saved the ball and made an iridectomy possible.

The general and constitutional symptoms of syphilis are in most cases sufficiently pronounced to enable one to determine the presence of this dyscrasia. For example, in the inherited form we have the facies syphilitica, the scarred mouth, the Hutchinson teeth, the enlarged glands or the scars of ulcerated and broken-down glands; in the acquired form, the history, the cutaneous stains, iritic synechiæ, chorio-retinitis, point unmistakably to the affection. When, however, there are no indications to be seen or learned, and when one must judge by the course of the inflammation following the injury for which the patient has come under treatment, one is guided by the amount of exudation disproportionate to the degree of inflammation, the nocturnal rather than the diurnal pain and its chronic course. I have not been able to determine that the danger of sympathetic inflammation is any greater in syphilitics than in non-syphilitics. It must be borne in mind in dealing with these cases in which iridocyclitis attacks the uninjured eye that it may be a manifestation of syphilis, developed, perhaps, in consequence of the injury and subsequent inflammation of the other eye for the same occult reason that acute glaucoma is lighted up in one eye after iridectomy on the other for glaucoma. Such accidents can not be attributed to sympathy, or, at least, to the affection of the second eye following traumatisms where the origin of that affection is derived undoubtedly from the traumatism and known as sympathetic ophthalmia. I feel very sure that some of the cases reported as sympathetic ophthalmia. and particularly those appearing weeks or months or years after enucleation are local manifestations in the hitherto sound eye of constitutional affections, with especial reference to syphilis.

DIABETES.

Injuries to the eyes of diabetics are almost invariably the cause of serious damage to, if not of the loss of, the eye. The truth of this statement can be abundantly verified. Those of us who have been careless in examining into the bodily condition before extracting a cataractous lens, or who have had the operation forced upon us, will agree they have had more failures than successes. The tendency of diabetics to gangrene is not more marked in any other portion of the body than in the eye, but fortunately the tendency becomes manifest only after injury. The uveal tract and the tissues that are dependent upon it for their health and growth give early indication of the blood impoverished by diabetes. Iritis, cataract, vitreous opacities and degeneration of choroid and retina in patches are common ocular complications of diabetes, and each of them is evidence of the disturbed nutrition. Now when an injury is the exciting cause of inflammation, the pre-existing tendency to involvement in the general affection will lead to results that are disastrous and entirely unwarranted by the character of the injury. For example, I have recently had under treatment a man who received on the cornea an apparently insignificant injury from impact of a small foreign body. The body was removed. The floor and edges of the wound became infiltrated with pus. In spite of the most active treatment, both for the abscess and the diabetes, the entire cornea was destroyed, exposing the iris and permitting of the escape of the lens and vitreous, necessitating finally enucleation. In another case preliminary iridectomy and massage of the lens for ripening of a cataract was followed by numerous hemorrhages into the anterior chamber, chronic iridocyclitis and loss of the eye.

We learn from these and similar cases: 1, the necessity for the examination of the urine for sugar preparatory to the operation for the extraction of cataract; 2, the obligation to consider all cases of injury serious until they are proven slight; 3, the necessity for strict remedial and dietetic measures in diabetes mellitus, and 4, in spite of treatment an unfavorable prognosis.

TUBERCULOSIS.

In individuals with a predisposition to tubercle, injuries to the eye, and particularly the penetration through the coats of cutting instruments or of foreign bodies, may give rise to local tuberculosis. This is brought about by one of two influences, namely, either the entrance with the foreign body of the tubercle bacillus or the stimulation to activity of bacilli pre-existing in a latent form at the site of the injury. The uveal tract and the contents of the vitreous and aqueous chamber furnish fertile soil for the multiplication of bacteria. Their growth is rapid, and equally rapid is the destruction of the function of the ball. The eye is destroyed by chronic iridocyclitis that is not amenable to treatment. As soon as the diagnosis is established by inoculation of part of the contents of the eye into the eye of one of the lower animals the ball should be enucleated. This is imperative. Delay will mean that the infection will become general and end in the death of the patient. We must expect similar processes of inflammation and disease to follow traumatism to the eye that are familiar in other parts of the body after injuries. Scrofula, which, in the opinion of some writers, is an hereditary form of diluted tuberculosis, is a predisposing cause to tardy healing of wounds, and should not be overlooked in the examination to determine the constitutional reason for chronic forms of inflammation after traumatism.

Early enucleation of a badly injured eye saves the patient and the surgeon annoyance and time, and has become, I think, a fashion. The patient's confidence in his physician must not be betrayed, and the most convincing argument in favor of enucleation, namely, the fear of sympathetic inflammation, should not be abused. One must be convinced beyond the shadow of a doubt that vision is irretrievably ruined before resorting to extreme measures. Nature's recuperative powers combined with human knowledge and antiseptic remedies accomplish wonderful cures. And sympathetic inflammation is not always as black as it is painted. It never follows immediately after the injury, it always gives warning and it may never come. I except from these rules eyes that contain a foreign body that can not be extracted. In the cases of foreign body in which the ciliary region is the site of the injury, or likely to become irritated by the presence of the body in the eye, immediate enucleation is the only safe treatment. The presence of a foreign body is indicated by chronic or recurrent intractable inflammation of the uveal tract. Sympathetic inflammation will supervene in three weeks or later, and can be prevented only by the extraction of the foreign substance or removal of the eye. There ought to be no uncertainty in the diagnosis, for unless the foreign substance is extremely small the *x*-rays will determine beyond reasonable doubt its presence. In all other classes of injury unless the traumatism is unusually destructive the expectant plan of treatment should be adopted and enucleation reserved as the last resort.

CONCLUSIONS.

1. Injuries to the ciliary zone are always serious and often destructive of the usefulness of the eye.
2. The syphilitic, diabetic or tubercular diathesis delays recovery and renders the prognosis uncertain.
3. Diseases of the uveal tract the result of injuries are favorably modified b[illegible]he energetic treatment of stitutional affe

4. Enucleation or one of its substitute operations is to be practiced immediately when a foreign body lies embedded in the ciliary region and can not be extracted, or when an eye is mangled beyond hope of redemption.

5. Conservative measures, such as cold compresses, antiseptic washes, subconjunctival injections, excision of prolapsed iris or ciliary body, rest in bed, restricted diet, morphia and other means to subdue inflammation should be the rule in other cases.

(The symposium on uveitis will be concluded next week by the papers of Drs. Wilder, Woodruff and Marple and the discussion.)

THE EMPLOYMENT OF DIGITALIS AND ACONITE IN THE TREATMENT OF CARDIAC DISEASE.*

H. A. HARE, M.D.
PROFESSOR OF THERAPEUTICS IN JEFFERSON MEDICAL COLLEGE.
PHILADELPHIA.

Among all the difficulties which have beset the subject of the proper use of drugs in disease, and there have been many, as we all know, it can not be doubted that the factor of greatest importance has been the employment of remedies by physicians without their having a correct conception, and sometimes no conception at all, of the pathological process underlying the condition which is to be relieved. This depends on the fact that many practitioners lack preliminary training, not only in morbid anatomy and morbid physiology or pathology, but also fail to study the possible effect of well-known drugs in abnormal states. The employment of certain remedies in disease has cast discredit on therapeutics by their abuse, while many physicians who have carefully studied diseased organs become so saturated, so to speak, with the seriousness of the lesions which they find that they scoff at the thought that drugs can be of service, forgetting that the vital factors are eliminated at the autopsy and that the conditions present represent a state so grave that death has taken place; that is, the worst possible state of affairs is seen. I have made these opening remarks because I do not wish to be considered a therapeutic optimist or nihilist, and because I so often emphasize the fault of using drugs when they can not do good that I fear I may be called a therapeutic unbeliever. In no class of cases does what I have said hold true with greater force than in that of cardiac disease. Some physicians are content to diagnose valvular disease, prescribe digitalis and ignore the state of the heart muscle, the state of the blood vessels and that of the kidneys, liver, and even the dose of the drug, so long as it is within bounds not poisonous.

It has always seemed to me that it is the duty of the physician to study the condition of the heart muscle, and almost entirely exclude any suppositions as to the condition of the valves of the heart. While this may be an exaggerated way of making the statement which I wish to emphasize, it is resorted to because in the majority of instances we are apt to endeavor to decide which segment is diseased without a correspondingly careful study of the condition of the ventricular wall.

Again, it is by no means an uncommon practice of physicians, after determining more or less carefully the condition of the heart, to fail to make a careful study of arterial tension, pulse force, and equally important, to attempt to discover whether there is arteriocapillary fibrosis. On the condition of the heart muscle, and on the development of arteriocapillary fibrosis much more depends in the diagnosis, prognosis and treatment of a case of so-called cardiac disease than is usually thought. It is also not permissible to reach correct conclusions in regard to these important factors in the case unless at the same time the renal condition is adequately investigated. And, again, it is not sufficient in many of these cases to be content with one or two examinations of the urine, which may fail to reveal albumin, unless at the same time estimations of urea are also made, and a careful record of the quantity of urine and of its specific gravity is kept. Not only do these renal conditions aid us in getting information concerning the probable condition of the heart muscle and of the blood vessel, but they also give us an insight into the ability of the kidneys to eliminate poisonous materials, and the drugs themselves, both of which, if retained to an abnormal degree, produce results which are disadvantageous.

I have within the last few years devoted a great deal of attention, not only to these factors in these cases, but also to the question of the proper administration of the various cardiac stimulants. and equally important, as to the dose which each individual patient needs from day to day.

Digitalis, like iron, has proved itself so valuable, doing good in so many instances which seemed grave, that we are wont to forget that, like most things which do good, it can also do harm, and judging from my previous habit. and from the habit of other practitioners, I am convinced that in the great majority of instances digitalis is administered in doses which are much too large, and often continued over a period which is far too long. It is by no means an uncommon thing to find physicians administering as much as 10 or even 20 m. of tincture of digitalis three or four times a day in cases of marked rupture of compensation. There can be no doubt that in some cases such doses are necessary at the beginning of the treatment to meet the crisis which exists, and in much the same way that we are wont to give large doses of mercury in early syphilis, afterward cutting the doses down one-half. so it may be necessary at times to give massive doses of digitalis, which, after a period, should be rapidly and considerably diminished. I have been surprised to find what excellent results I could produce by the use of such small amounts as one or two minims of an active, physiologically tested tincture of digitalis given three or four times a day, the patient being, of course, required to rest and so give his heart that most needed therapeutic aid when its compensation is ruptured.

Apropos of this, I may add that in my belief we often fail to get results from doses and from drugs on which we rely, more because we are careless as to the physiological activity of one product than because we have made an error in judgment as to the remedy which is needed or the dose which is required. With the important subject of the employment of drugs closely related to digitalis in the treatment of various cardiac conditions there is not space to deal in this paper. In deciding what cardiac stimulant is required in a given case we must not only consider the condition of the valves and the myocardium as already indicated, but we must, if possible, reach some conclusion in regard to the state of the coronary arteries. Digitalis, which improves the nutrition of the heart, largely by improving the circulation in these arteries, can manifestly do more harm than good if these nutritive vessels are so nearly closed that it is impossible for the heart to pump blood through them in increased quantity; and again, if the myocardium has undergone such advanced degeneration that it is impossible for the digitalis to improve the nutrition of the heart, although at the same time it may be driving the remaining healthy fibers to an endeavor far in excess of their ability.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

I am also quite sure that in a certain number of cases of valvular disease the patient does not require digitalis or any other cardiac stimulant for the relief of his cardiac symptoms; but, on the other hand, in addition to rest, will often be greatly benefited by the administration of aconite, which has a steadying effect on the heart through its influence on the vagi as has digitalis. By its sedative influence on the heart muscle in hypertrophy, which sometimes produces an excessive irregularity, and by its relaxing effect on the blood vessels, it produces good results. It is much easier for us to conclude, in the case of valvular disease, with dyspnea and disturbed heart action, that these symptoms are due to a failing heart than that they are due to a hypertrophy and an excessive activity. Such cases I have frequently seen in men who are well developed, in the muscular sense, and whose occupation has caused them to do heavy manual work or who take part actively in some of the severe athletic games. And not infrequently have I seen other cases in which the use of well-balanced doses of aconite and digitalis have produced results which neither drug could produce by itself, although at first glance they are physiological antagonists.

Finally, the utter uselessness of expecting good results from either of these drugs in the treatment of certain cases of myocardiac disease which persistently take severe exercise "for their health" needs to be emphasized. I have repeatedly seen cases of men of advanced years with somewhat fibrous vessels who have mistaken the heaviness of advancing years for the heaviness of lack of exercise, and who on the golf field, on the bicycle, or by rowing or walking, have tried to drive away the symptoms from which they suffer, with a result that sooner or later the condition from which they are suffering becomes greatly aggravated and they become more or less invalids if they are so fortunate as to escape sudden or nearly immediate death from their ill-judged efforts. It seems to me, too, that when we are attempting to treat such cases, and are endeavoring to administer doses and remedies as accurately as possible, we should insist on a quiet and careful mode of life until we are able to determine that the remedies suit the case. Otherwise the change of exercise or change in diet may not only prevent the remedies from doing good, but also warp our judgment as to the plan of treatment, and so prevent us from instituting it in another case, when in reality had proper precautions of this kind been taken we would have increased confidence and been able to do much more good to a large class of patients. It is not to be forgotten that every one in this room sooner or later, according to his years, his inheritance and his mode of life, develops more or less arteriocapillary fibrosis, degeneration of his myocardium and sclerotic changes in his kidneys.

I may close by saying that curiously enough a very large proportion of the patients to whom I have just referred are physicians who, after a long life of intense nervous strain, not infrequently find themselves at a comparatively early age suffering from disorders of the heart the true nature of which they fail to recognize, either because on examining this organ they fail to discover murmurs, or because they do not appreciate the fact that a physician's life is peculiarly apt, as is that of the banker and large business manager, to develop degenerative cardiac changes. The employment of strychnin, belladonna and other drugs in connection with digitalis and aconite might be considered if time permitted, but they are not included in the title of this paper and therefore can not be discussed.

DISCUSSION.

Dr. H. B. Favill, Chicago—The paper of Dr. Hare deserves very thoughtful attention, inasmuch as it bears on one of the most perplexing of therapeutic puzzles. How to avail ourselves of the valuable powers of digitalis, at the same time escaping its disadvantages, has been a great problem and becomes steadily a greater problem as these disadvantages become more obvious. In general, this is a parallel procedure to that of combining digitalis and nitroglycerin, though there are decided differences in the deeper physiologic activities. The latter combination is by no means uniformly satisfactory, and there is no doubt that the suggestion of Dr. Hare is important as an additional resource under these indications. I shall make it a point to employ this combination under appropriate conditions.

Dr. Allen A. Jones, Buffalo—I agree with what has been said regarding the danger of digitalis in large doses when there is myocardial disease, especially when due to disease of the coronary arteries. In a case recently observed, a man of some age took 10 minim doses of digitalis every four hours. When I saw him he was almost in collapse. The pulse was extremely slow and the heart had apparently stopped beating. He certainly was in bad shape. Under the use of nitroglycerin and strychnin, absolute rest and proper management, the man recovered. I warned him against the danger of using digitalis in that way.

Dr. J. M. Anders, Philadelphia—I was much impressed with the sound advice given by Dr. Hare and am quite of the same opinion regarding the giving of too large doses of digitalis, and the too long-continued use of this drug. Allusion was made to the combined use of digitalis and aconite in certain conditions; while the Doctor did not consider the other remedies often combined with digitalis it seems to me that a brief allusion should be made to nitroglycerin, which should guard the action of digitalis, more particularly in hardening of the vessels. Nitroglycerin is of service where the myocardium is the seat of fatty or fibroid change and the blood vessels sclerotic. This drug does not weaken the action of the heart. On the contrary, in small doses it is a cardiac stimulant and a combination of nitroglycerin with digitalis acts well in certain cases as a stimulant to the heart, while at the same time it widens the blood paths. I have had no experience with the combined use of aconite and digitalis.

Dr. Hare, in closing—Of course, it goes without saying that I am in accord with what Dr. Anders has stated with regard to nitroglycerin and digitalis. Digitalis should rarely be prescribed unless a careful study of the pulse tension is made, for we know that digitalis will increase the pulse tension. Regarding the study of digitalis, I instruct my students how to give this drug to a patient whose heart is failing, by the following simile: If you see an old man staggering under the weight of a bundle of fagots there are two ways to relieve him: first, give him a drink of whisky, which will increase his endeavor; second, or better still, remove some of the fagots. So with digitalis in cardiac diseases. If you give digitalis without nitroglycerin to guard against the increased rise of pressure, you stimulate the heart without removing its burden; if you combine the nitroglycerin with the digitalis, you both stimulate the heart and also relieve it of some of its burden.

I did not have an opportunity in my paper of calling attention to a factor in connection with the influence of digitalis which is comparatively a new one. Two or three years ago an excellent paper was published in the *American Journal of Physiology* in which it was pointed out that the heart muscle was not only nourished through the blood flowing through the coronary arteries, but also through openings of the foramina

Thebesii. The wide mouths of these various vessels open and become filled thoroughly with blood and then, by a secondary capillary circulation through these vessels, the heart muscle is supplied with fresh blood. I do not doubt that there are many cases found at autopsy with advanced degeneration of the coronary arteries showing that digitalis given alone would be useless, perhaps injurious. Then, again, such an appearance might controvert the idea that digitalis is useless, for the benefit the patient has received may be due to the influence of the drug on the heart muscle carried there through the veins of Thebesii. I feel quite convinced that the blood so carried to the heart will readily part with its oxygen and nutritive material. I have always felt that the subject of the use of digitalis was an important one because of the grave condition of patient. I am convinced that many physicians do not have a sufficient regard for the pathology of the heart, i. e., the morbid physiology of the heart. I think this is one of the faults of the medical course of to-day; students are taught to listen to diseased hearts, but little is taught them about the proper function of the organ; they are told what happens in a normal heart in its normal cycle, but not informed as to what happens to the heart when it is diseased, or if the valves are destroyed. They are not taught enough about the employment of the different stimulants on such a heart. I am convinced that physicians who understand the use of chloroform and ether, who use chloroform in some cases and ether in others, nevertheless treat every case of valvular disease of the heart with digitalis as a routine method. When administering this drug one should first study the condition of the heart muscle and its valves and arteries.

THE ORIGIN OF THE VESICULAR RESPIRATORY SOUND.*

C. F. HOOVER, M.D.

CLEVELAND, OHIO.

The origin of vesicular breathing was attributed by Laennec to friction of the inspired air in the bronchioles and its entrance to the infundibula from the bronchioles. This inflammation was sanctioned by such masters as Skoda and Wintuch and remained unquestioned, so far as I am able to learn, until Baas attempted to explain on purely acoustic grounds the improbability of any audible sound originating in tubes the size of the bronchioles from the passage of a current of air with the slow velocity which must attend the entrance of inspired air in the vesicles of the lung. Baas' article published in the Deutsche Arch. für Klin. Medicin, vol. xix. 1876, is a profoundly thoughtful and logical discussion of the subject which was well calculated to carry conviction to the mind of the reader. I was greatly impressed with the acute reasoning of the author the first time I read the article several years ago, but in the light of recent clinical experience and the attempt to confirm some of Baas' observations, I am reminded of the voluminous monograph on the habits of the camel, the contents of which emanated from the inner consciousness of the author.

Penzoldt later offered experimental evidence to sustain the logic of Baas. The experiments of Penzoldt were very simple. They consisted in inflating a calf's lung and placing it over the trachea of a man who is instructed to breathe in the ordinary way. If a stethoscope be placed on the inflated lung the observer will perceive (according to Penzoldt) the tracheal breathing transformed to the vesicular type of respiration. This is accounted for by the refraction and partial reflection of sound waves which must occur during their transmission through such heterogeneous media as are presented in the inflated lung. If a more homogeneous medium be used, such as the calf's liver (according to Penzoldt) the tracheal breathing retains its so-called bronchial character. Sahli tried the experiment as described by Penzoldt but found the respiratory murmur transmitted through the inflated lung retained its bronchial character. The only modification, according to Sahli is a diminution in intensity of the respiratory sound.

My own observations confirm those made by Sahli. In repeating this experiment it seemed to me that only a vigorous use of the imagination could transform the audible sound into a vesicular murmur or anything approximating it. Vesicular breathing and bronchial breathing have several essential differences which will not admit of the transition of the former to the latter on the acoustic grounds cited by Baas. The terms, sound and murmur, are differentiating terms which are descriptive of two phenomena. Bronchial respiration gives a clearly definite, and simple sound which can be assigned a certain pitch. Vesicular respiration gives a confused mingling of sounds which suggest a multiplicity of points of origin. The pitch is much lower and the expiratory sound is much shorter in duration than in bronchial breathing. However remote and faint bronchial breathing may be, the duration of the expiratory sound remains the same, whereas, in vesicular breathing the expiratory sound is relatively short, whatever may be its intensity or proximity.

The observations on the case I am about to report offer absolute proof of vesicular breathing having an origin different from that of bronchial breathing:

I was called one evening to see a man 82 years old who, during the same day, had developed a violent hiccough. The patient had a temperature of 101 degrees. The base of the left lung posteriorly gave a high-pitched tympanitic percussion note with increased resistance. Tactile fremitus was not increased. During inspiration were an abundance of medium and fine moist râles. The respiratory sounds over the affected area was slightly higher in pitch, but unfortunately for the completeness of my observations, the sound had not acquired a bronchial character. The hiccough presented a very striking picture, and would recur about every half-minute during a period varying from one-half to two hours, and then disappear to return after an interval of three or four hours. So, the hiccough was present about four to six hours in every day. The patient laid 14 days in this condition until death came in the form of vagus exhaustion, so there was ample opportunity to study the details of the hiccough. The hiccough occurred frequently during sleep without waking the patient. Each attack commenced with a moderately loud laryngeal sound and was followed directly by from ten to twenty violent retractions of both hypochondria at the rate of about two to a second. The hypochondria fairly flopped, so that it strongly suggested the flopping of the wings of a barnyard fowl. The spasms of the diaphragm occurred in such rapid succession that a complete evolution of the diaphragm phenomena was not discernible, though the band of retraction over the pleural sinus was plainly visible. The contraction of the diaphragm lasted so short a time, the descent of the lung was so slight, it could not be demonstrable by percussion, though on occasions it was slightly perceptible to the eye. Auscultation during the attacks revealed a loud respiratory murmur everywhere over the lungs, over the apices, as well as the bases, which though short in duration plainly gave the characteristics of vesicular breathing. The duration of the sound during the relaxation of the diaphragm sustained the same relative duration to the sound during phrenic contraction which the expiratory sound sustains to the inspiratory sound during normal respiration. Over the infiltrated lung area râles could be distinctly heard during the contraction of the diaphragm, though not with the same intensity as with forced inspiration. If the stethoscope was placed over the larynx or trachea during the spasms of the diaphragm there was no sound audible. It was perfectly clear that with the onset of each series of phrenic contractions the glottis was tightly closed. That there was movement of the air contained in the respiratory tract toward the infundibula is proven by the occurrence of râles over the pneumonic area, but this was accomplished by rarification of air in the trachea and larger bronchi.

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

The observation offers absolute proof of the existence of a true vesicular respiratory sound. Whether the sound is due to the disturbance of equilibrium of the lung tissue or to motion of the contained air, or both, is not determined, and I see no possible method of differentiating between these two factors as they are both essential premises for any clinical or experimental observations which can be made. In this case laryngeal and tracheal breathing were eliminated, there was an increase of the antero-posterior diameter of the thorax with each spasm of the diaphragm. All the muscles employed in inspiration were brought violently into action. The volume of the thorax was increased with each spasm of the inspiratory muscles by rarifying the air contained in the respiratory tract, and still the typical murmur of vesicular breathing was audible.

The nearest approach to these conditions I have found was in the case of fissured sternum, reported by Sahli. But in Sahli's case tracheal breathing was not eliminated. It would be impossible to reproduce the conditions of this clinical observation by any animal experiment. I can not conceive of such violent inspiratory efforts being produced by stimulation of the phrenic nerves alone. Since making the above clinical observation I have made the following experiment: On a healthy man, have the subject close the glottis and then make a violent inspiratory effort. At the same time auscult the lungs and you will hear a faint vesicular respiratory sound during the inspiratory effort and a faint expiratory vesicular murmur as the muscles are relaxed, though the glottis remain shut. The sound heard during relaxation of the inspiratory muscles is lowered in pitch and short in duration. The two sounds are identical in their character and their relations with the normal vesicular respiratory murmur. The sounds produced in this manner by a strong man do not, however, approach the intensity of the sounds produced by the old man with the pneumonia.

REPEATED SMALL HEMORRHAGES AS A CAUSE OF SEVERE ANEMIA.*

JAMES B. HERRICK, M.D.
CHICAGO

That recovery may rapidly follow a severe acute hemorrhage is well known. Even repeated severe hemorrhages may cause no permanent deviation from health, if the intervals between hemorrhages be sufficiently long to permit regeneration of blood to take place. The body may also stand repeated small losses of blood at shorter. even daily, intervals, with little or no perceptible change in the blood or in the performance of function on the part of any organ. Repeated hemorrhages from the nose, from hemorrhoids, from uterine fibroids may thus be endured for months or for years, the tolerance of the individual to the loss of blood and his power of blood regeneration being sufficient to withstand and make up for the daily drain. But in other instances, the daily loss of small amounts of blood produces the most severe and even fatal forms of anemia. It is my purpose in this brief paper to call attention to the importance of recognizing this form of anemia; and I treat the question from the practical and clinical, rather than from the hematologic point of view. My attention has been called to this subject by having seen five patients with bleeding piles in whom there developed a most grave secondary anemia. And I am led to write on this topic because in all of these cases the cause was for a long time overlooked and because in three of them even when the nature of the anemia had been pointed out, there was a disinclination on the part of some to regard so common and so insignificant a condition as bleeding piles as the cause of an anemia so profound and so clearly threatening life.

CASE 1.—The first case I saw while acting as assistant to the late Charles Warrington Earle. After trying in vain by iron, arsenic, tonics, rest, etc., to restore color, strength and health to a previously robust man, Dr. Earle decided to operate on the bleeding hemorrhoids. The result fully justified his suspicions as to the nature of the anemia, for the man made an uninterrupted recovery within a few weeks.

CASE 2.—The second case was the wife of a physician. She presented the typical appearance, symptoms and blood findings of a severe chlorosis. For weeks she had been losing blood with every bowel movement, often several ounces at a time. Iron and other remedies were without perceptible effect. The immediate operation that I advised was deferred because of the weak condition of the patient, a slight temperature and a loudness of the hemic murmur which made the surgeon feel that there was an organic heart lesion that might account for the anemia and that contra-indicated an anesthetic. Several months later when the patient could scarcely walk across the floor without fainting, and when my second examination confirmed the previous findings of a grave secondary anemia, most urgent advice was again given as to operation. The hemorrhoids were attended to, the anemia disappeared and the patient has ever since been in perfect health.

CASE 3.—A third patient, an old man in the sixties, had an appearance suggestive of malignant growth. Yet there could be found for his profound anemia of the chlorotic type, no tumor, tuberculosis, nephritis or other cause than some hemorrhoids that had bled daily for nearly three years. He refused an operation and was lost sight of. His blood on May 18, 1901, the date of the first examination, showed 2,450,000 red corpuscles, 6000 whites (74 per cent. polymorphonuclear), no nucleated reds, hemoglobin 29 per cent. The cells were smaller than normal, volume index .72, the time of coagulation was four minutes.

CASE 4.—The fourth case which I report more in detail concerns A. K., a Bohemian of 39. His family history was negative and he himself had pursued his occupation as a butcher, annoyed by no illness up to two years before the time I first saw him, the fall of 1901. In 1899 he had articular rheumatism and was kept from work for several weeks. From this he recovered. In September, 1900, he noticed that he was passing blood at stool. The amount was often several ounces, frequently a half teacupful being passed. He grew pale, weak, dyspneic, dizzy and by May, 1901, could barely keep at work. His feet and ankles by this time were edematous. Medicines seemed to do him no good and in August, 1901, he took to his bed, which he had left only rarely since. The bowels moved once a day, a varying amount of blood being lost with nearly every movement. He was under my care for a time in the

---

*Read at the meeting of the Illinois State Medical Society at Quincy, May 22, 1902.

Cook County Hospital. Here a surgeon refused to operate on him until I had improved his general condition, saying the piles could well enough wait awhile and needed only suppositories. The patient later came to the Presbyterian Hospital, and I quote from my records of the case while he was in that institution.

Examination.—Oct. 30, 1901, he was seen to be extremely pale, with a hint of a lemon-yellow in the waxy whites of the eyes. He was somewhat emaciated, listless and apathetic as are many patients in the last stages of pernicious anemia. He was extremely weak. His lungs were clear. The heart showed no change except a systolic murmur, evidently hemic. The venous hum was marked. The abdomen and genitalia showed nothing abnormal. There was a slight edema about the sacrum and the ankles. The rectum bled on digital examination, its walls were soft, there was no stricture. On straining he brought down several large hemorrhoids that dripped blood. The examination for motor or sensory disturbances was negative. The retina was negative. His urine contained no sugar, albumin or casts. He had an evening rise of temperature at times to 100°. His pulse averaged 84, his respirations 24. The blood examination made Oct. 29, 1901, was as follows: Red corpuscles, 2,184,000; white corpuscles, 4200; hemoglobin (Fleischl, 3 tests) 19 per cent.; color index 0.44; time of coagulation, three minutes.

In the stained specimen the red corpuscles showed great variations in shape and size, the greater number being undersized. The color of the corpuscles was poor and there was fairly well-marked polychromatophilia. In a careful and prolonged search one nucleated red of the megaloblastic type was seen, and five normoblasts. Of the leucocytes the polymorphonuclear neutrophiles made up 44.6 per cent., polymorphonuclear eosinophiles 3.0 per cent., small mononuclear lymphocytes 35.7 per cent., larger lymphocytes 16.4 per cent. There were 0.3 per cent. of basophiles. Many subsequent examinations were made by myself and by different members of the house staff. The results were practically the same. The hemoglobin reading was generally made by taking two or three capillary tubes of blood instead of one and dividing the total reading by 2 or 3 as the case might be, seeking in this way to lessen the possibility of error that so easily creeps in when the hemoglobin is low. In my office, later, I also controlled by the Tallqvist color test. From these many examinations I quote only some of the more pertinent findings. November 4, the specific gravity was found to be 1034 by Hammerschlag's method by two examiners. The volume index, i. e., the number of corpuscles found by the hematocrit divided by the number found by the hemocytometer, was estimated at different times and also found less than 1, varying from .66 to .86. The findings seemed typical of a severe anemia of the chlorotic or secondary type. The small size of the corpuscles, the abnormally low color index, the rapid coagulation, the scarcity of nucleated reds, those found being almost exclusively normoblasts—all this seemed to rule out the primary pernicious anemia.

The bleeding hemorrhoids were looked on as the probable cause and operation was decided on. This was deferred for several days because of a peculiar and puzzling attack that the patient had on November 6. November 4 he vomited, also fainted while in the bathroom. On the evening of November 5 his pulse rose to 128, his respiration became short and shallow, 30 to the minute, his temperature reached 100.2°. His muscles twitched and he became stupid and semi-comatose, muttering to himself, picking at the bed-clothes, having retention of urine. There was no paralysis. In twenty-four hours he gradually regained consciousness. The exact nature of this coma is not clear. It was probably some form of intoxication. Color is lent to this theory by the fact that for several days he had not only been taking good-sized doses of iron and arsenic but he had been on full diet, in reality over-eating, with resulting gastro-intestinal disturbance. This may have been the source of the toxemia that in his weakened condition produced these alarming symptoms. During this attack the leucocytes rose to 14,800.

Following this attack he was kept quiet, given food more cautiously, also iron and tonics. His condition remained about the same as before. There were daily losses of blood. Late in November, under cocain anesthesia, as a general anesthetic seemed too hazardous, Dr. A. D. Bevan injected the four large hemorrhoids with equal parts of carbolic acid, water and glycerin. Dr. Bevan admits that he was skeptical as to the hemorrhoids being the cause of the unusually severe anemia, but operated at my urgent solicitation. From that time up to April 12, 1902, when I last saw him, there had been no more bleeding. Iron has been continued, generally in the form of Blaud's pill. The abbreviated blood counts are as follows:

Dec. 5, 1901.	R. b. c. 2,784,000. Hb. 27.5 per cent.
Dec. 21, 1901.	R. b. c. 3,800,000. Hb. 37 per cent.
Jan. 3, 1902.	Hb. (Fleischl) 61 per cent. (Tallqvist) 60 per cent.
Feb. 21, 1902.	R. b. c. 3,920,000. Hb. (Fleischl) 72 per cent.
April 5, 1902.	Hb. (Fleischl) 90 per cent. (Tallqvist) 85 per cent.

For several weeks he has deemed himself to be as strong as ever, with no dyspnea, having a good appetite and digestion. He has regained the appearance as to color and weight of a healthy man. He is prevented from working by a return of the rheumatic pains in his hands and feet. The joints have shown redness and swelling. He has had an occasional temperature of 99.4° when he has been in my office.

Case 5.—A case similar in many respects to this one was in the Presbyterian Hospital at about the same time, under the care of Dr. Palmer Findley. Through Dr. Findley's kindness I was enabled to see the patient several times. There was a history of bleeding piles for several years, the bleeding having been for ten months very severe. The ordinary anemic symptoms were present in the shape of dizziness, occasional attacks of syncope, palpitation, etc., and the same blood characteristics as in the other case, the hemoglobin being at first 18 per cent. and the red blood corpuscles 1.952,000. An operation on the hemorrhoids was done and the patient continued to improve, though slowly. At the time of leaving the hospital, six weeks after admission, he had 3,016,000 red corpuscles and 36 per cent. of hemoglobin.

The practical lesson to be drawn from these cases is perfectly plain. It is that severe anemia threatening life and producing a pallor and weakness equal to that of the pernicious variety, or suggesting some hidden malignant disease, may at times be caused by repeated small hemorrhages often from a condition as easily recognized and easily remedied as hemorrhoids. This form of anemia may prove fatal; and cases of a transformation of the type into the pernicious are reported, especially by English writers; and Ehrlich inclines to the belief that the pernicious variety may have its origin in repeated hemorrhages. The careful blood examination showing the chlorotic or secondary type of anemia should give encouragement for immediate measures looking toward a checking of the hemorrhage. The hemorrhage once stopped, recovery, though it may be slow, is generally complete.

103 State Street.

An overcrowded profession would not be the burden of professional complaint if the people were taught to employ medical counsel earlier, oftener, and to retain it longer as they should, before people have to be sent to bed by illness. Twice as many physicians are needed by the people as are employed. In times when epidemics are pending or approaching the people should be put in organic and functional condition for meeting and successfully combating disease. It is now the custom to wait till the human machine is broken and prostrate before asking medical counsel and aid.—*Alienist and Neurologist.*

A NEW INSTRUMENT FOR INTESTINAL ANASTOMOSIS.*

E. M. LUNDHOLM, M.D.
SURGEON TO BETHESDA HOSPITAL
ST. PAUL, MINN.

During my sojourn in Europe in the summer of 1900 I spent a considerable portion of my time performing surgical work on the cadaver, to which I had ample opportunity. It was then that I conceived the idea of constructing an instrument to facilitate intestinal anastomosis. After my return to St. Paul I commenced experimenting in that direction, and soon produced an instrument which, after a few modifications, proved to be very satisfactory. In hope that it will be accepted as an addition to our surgical armamentarium I hereby wish to present it to the profession.

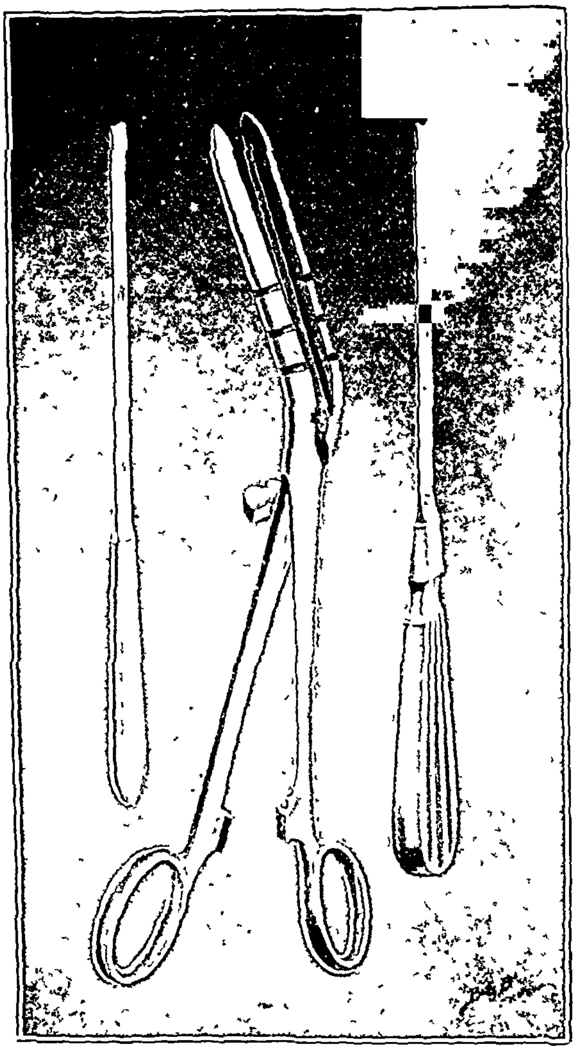

Fig 1 —Intestinal anastomosis forceps 1 Longitudinal grooves on inner surfaces of the blades, forming a rectangular tunnel closed at one end when forceps are locked 2 Transverse grooves extending around outer surfaces of both blades 3 Sharp-pointed sliding stylet, to be introduced into the tunnel formed by the grooves in order to cut the intervening visceral wall 4 Blunt sliding stylet to be heated and introduced into the tunnel after cutting is done, thereby preventing eventual hemorrhage

It appears, as we notice, similar to an ordinary clamp forceps the blades of which are dull-pointed and bent at an angle of about 125 degrees to the handles. The inner surfaces of the blades, which, by the way, are not *toothed or corrugated, but plain, have each a* deep longitudinal groove going from the angle nearly to the point of the blades. When the forceps are locked those grooves are placed opposite each other, forming a rectangular tunnel into which a narrow, sharp-pointed stylet, going with the instrument, is to be introduced at the operation. When the forceps are wide open the blades can be taken apart and put together as an ordinary hemostatic forceps. But by loosening the nut of the thumbscrew a couple of turns the blades can also be taken apart and put together when only a little open. *This is of great advantage in some operations where lack* of space does not permit the blades to be spread out sufficiently. In order to determine how far the blades are introduced both blades are graduated with three narrow transverse grooves 1 cm. apart, which also serve as fixing points for the puckering string by which the edge of the visceral opening is tied around the blades.

Gastro-enterostomy, both anterior and posterior, as well as all kinds of lateral anastomoses, is made comparatively easy and safe with this instrument. End-to-side and end-to-end anastomoses are more difficult.

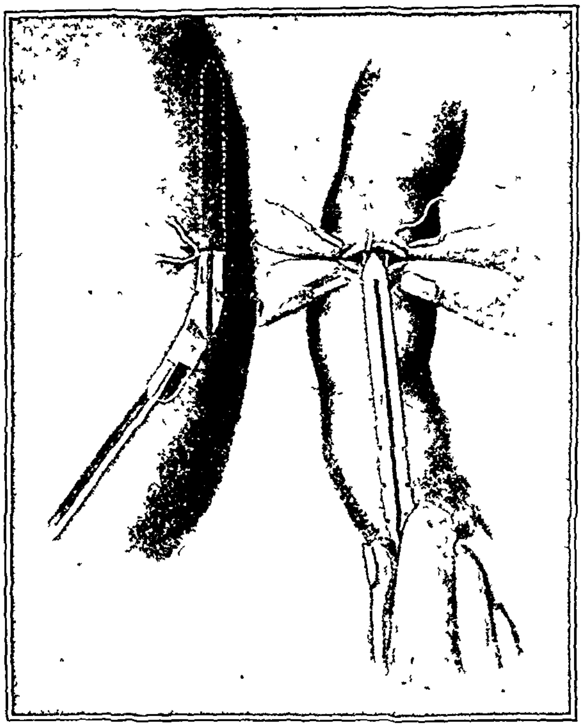

Fig 2 —Showing first steps of operation. One blade of forceps *has pierced gastric wall and is held securely* in position by tightening and tying the puckering ligatures in one of the transverse grooves This also protects from possible leakage of stomach contents The other blade, in the operator's right hand, is held ready to be pushed through into the lumen of the intestine in the *center of the pucker In order to guard against* accidental *penetration of* both intestinal walls, the anterior wall is held up steady by thumb and *index finger* of operator's left hand (to the left on the figure), and also in the same manner to the right by an assistant.

THE METHOD OF USE.

The surgical technic is simple. The abdomen having been properly opened, the bowels to be approximated are drawn into the opening and the forceps taken apart. The part of the bowel selected for anastomosis is lifted up and stretched transversely between two folds and one blade pushed into the bowel as far as desired, care being taken, of course, not to penetrate the opposite intestinal wall. The same thing is done with the other *bowel and the forceps are locked. As the blade has a* tendency to slide out again before the forceps are locked I generally first put in a puckering string around the spot where the blade is to be introduced, and after the blade is pushed in that string is tied over one of the transverse grooves. The distal end of each blade is now inside of its respective viscus, firmly pressing together the walls of the viscera to be approximated. With a continuous silk suture the adjacent surfaces of the bowels are now united, the sewing being very easy when the bowels are held stretched over the blades. The silk suture is to penetrate all the coats. Then follows a catgut suture, uniting only the serosa and possibly the submucosa. The sharp-pointed stylet is next pushed into the tunnel formed by the longitudinal grooves, whereby the intervening visceral walls are divided and the desired communication established. In gastro-enterostomy a heated, dull-pointed stylet is next introduced into this tunnel in order to prevent eventual hemorrhage after removal of the forceps. This latter procedure may not be necessary, but, as the stomach wall generally has some tendency to bleed. I have resorted to it as a safeguard. The instrument is unlocked and withdrawn and a few stitches of silk and catgut will close the remaining opening, thus completing the anastomosis. The operation is much more easily demonstrated than described.

---

* Read and demonstrated before the Ramsey County Medical Society, St Paul, Minn

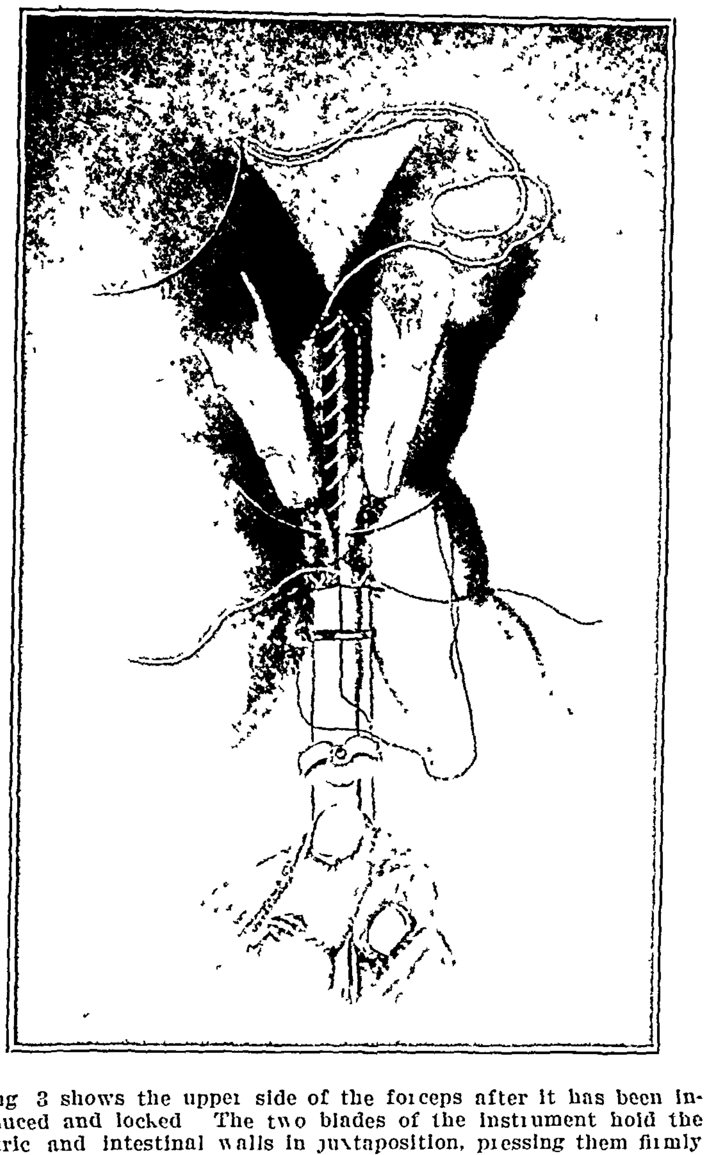

Fig 3 shows the upper side of the forceps after it has been introduced and locked The two blades of the instrument hold the gastric and intestinal walls in juxtaposition, pressing them firmly together. The original puckers are seen tied around the blades. A continuous silk suture (white) going through all the layers and also a superficial catgut (black) are sewed over the upper surface of the instrument. Note that the ends of both silk and catgut sutures are left long to be tied with the other ends of the same sutures when suturing is completed all around the anastomosis and instrument removed The forceps are held by an assistant and the fingers of the operator's left hand are holding the parts to be sutured somewhat tense over the instrument, thus very materially aiding the placing of the sutures.

OTHER SIMILAR INSTRUMENTS.

When I first had my instrument made I was satisfied that it was something entirely new, until a friend of mine directed my attention to an instrument constructed on the same principle by Dr. Ferguson of Chicago. He again claims that his instrument is a modification of a similar one devised by Dr. Grant of Louisville, Ky. A short time ago I had opportunity to see Dr. Ferguson's instrument, but I have never seen Dr. Grant's. Although my instrument differs from Dr. Ferguson's in numerous details, and I dare say is superior to his. I can, of course, not claim priority for the principle on which it is constructed. The same belongs probably to Dr. Grant. The forceps of Dr. Laplace, McLean and O'Hara as well as Murphy's button have nothing in common with this.

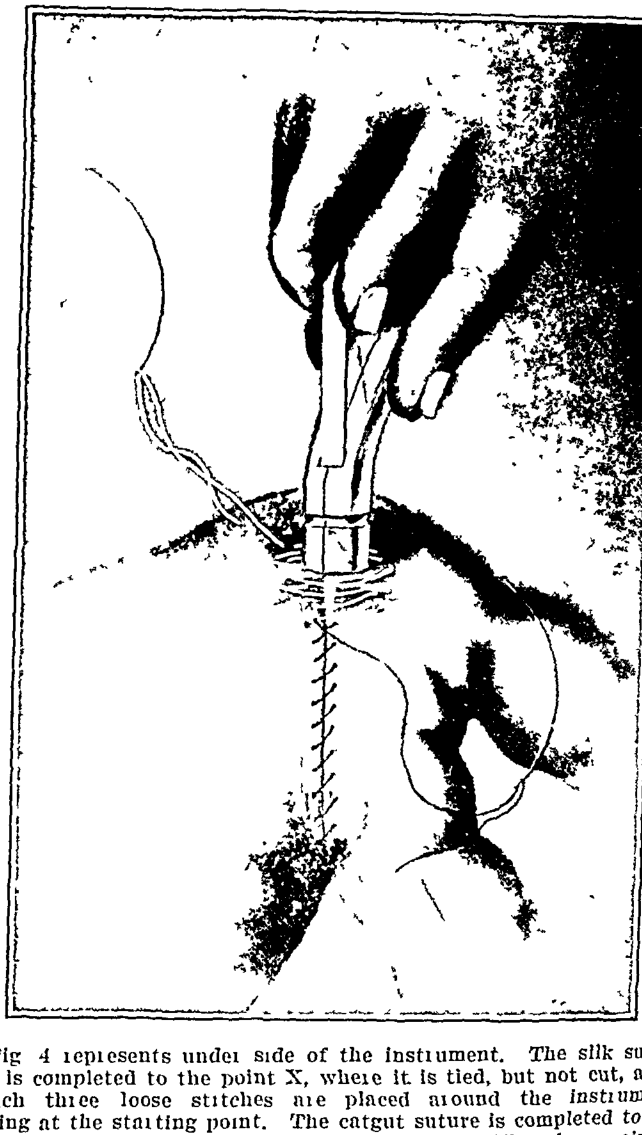

Fig 4 represents under side of the instrument. The silk suturing is completed to the point X, where it is tied, but not cut, after which three loose stitches are placed around the instrument, ending at the starting point. The catgut suture is completed to the point * where it is also tied and left long. The sharp pointed stylet is pushed into the tube formed by the two longitudinal grooves in the blades, thereby severing the intermedial visceral walls and also the two pursestring ligatures which were placed primarily around each blade.

I have extensively tested this instrument on cadavers, but so far made only nine anastomoses on six living persons, all of which proved eminently successful.

In gastro-enterostomy I have always performed the anterior one, but the posterior could with this instrument, be performed just as easily. The jejunum has been attached to the stomach about 50 cm. from its upper end and always isoperistaltic. The entero-anastomosis is about 20 cm. below the gastro-enterostomy. Lavage of the stomach before the operation has not been done in the last four gastro-enterostomies, and I never needed to do it after the operation. Generally, I commenced to give my gastro-enterostomy patients light diet on the second day after the operation, or as soon as the effect of the anesthesia had disappeared, and full diet about a week after the operation.

NARRATION OF CASES.

Case 1.—Mrs. J., 48 years old. Gastric trouble for over ten years and during last month daily vomiting after meals. Tumor palpable in epigastrium. Very anemic and cachectic. Diagnosis: cancer of the stomach. At the operation the anterior wall of the stomach was found extensively adherent to the anterior abdominal wall, the loosening of which resulted in tearing a big hole in the stomach whereby some of the gastric contents escaped into the abdominal cavity. After extensive resection and repairing of the anterior stomach wall anterior gastro-enterostomy *without entero-anastomosis* was performed with this instrument. Perfect recovery. Several months after the operation I saw this patient again, perfectly well as far as her stomach was concerned, but complaining about lumps on her neck, evidently cancer metastases, from which she finally died without having experienced any more trouble from her stomach.

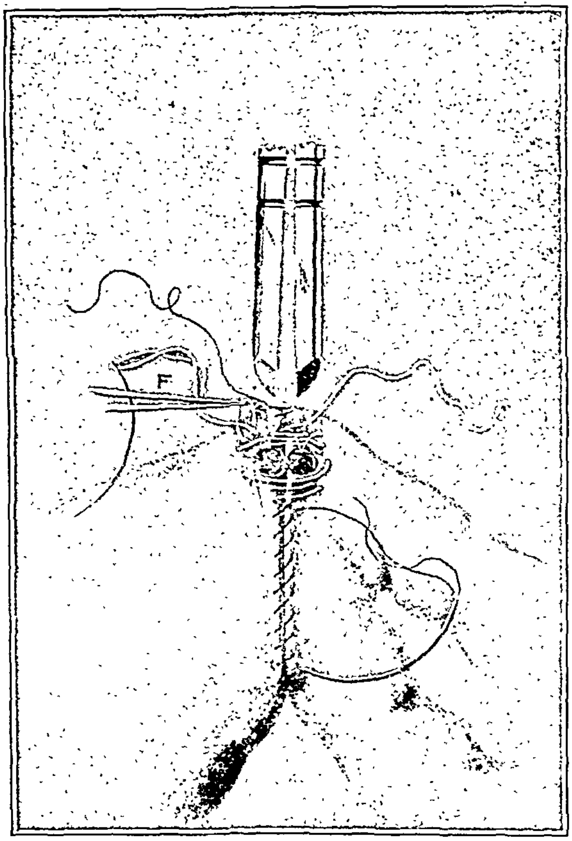

Fig. 5.—The instrument is removed. The primary puckers around each blade of the instrument, which were cut by the sharp-pointed stylet, are picked up by a dissecting forceps, F. The edges of perforation produced by the instrument are to be inverted, the stitches already placed tightened and the two ends of the silk suture tied together.

Case 2.—Mrs. L., 48 years old. Gastric trouble with vomiting for years, several times bloody. No palpable tumor. Very anemic and poor. At the operation was found a large pyloric tumor and extensive metastases in both omenta. Anterior gastro-enterostomy without entero-anastomosis with my forceps. This patient was considerably improved by the operation but had, as well during her stay at the hospital as afterwards, several attacks of circulus vitiosus. From my experience in this case I have always since combined gastro-enterostomy with entero-anastomosis.

Case 3.—Mrs. M., 60 years old. Symptoms of partial intestinal obstruction for years. Movable, palpable tumor in lower part of abdomen. Anemic and poor. Operation. Intestinal tumor as large as a fist, apparently malignant, narrowing the lumen to the size of a lead pencil and numerous metastases in mesenterium and retro-peritoneal tissue, some of them impossible to remove. Intestinal anastomosis with my forceps. Left hospital evidently cured of the symptoms of obstruction and has not been heard from since.

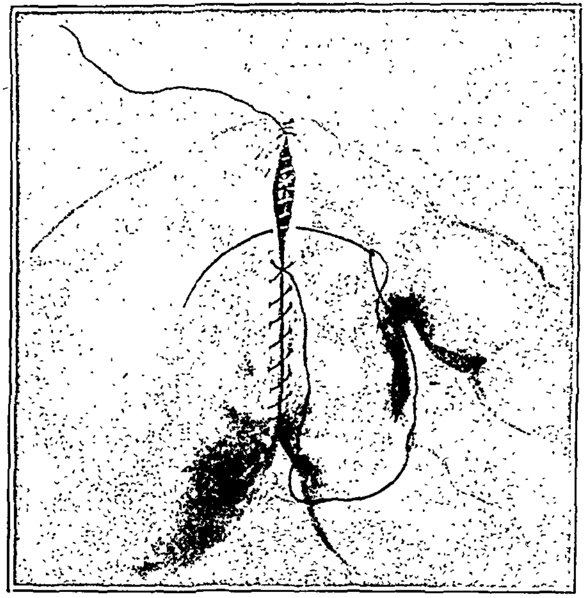

Fig. 6 shows the silk suturing completed. The last two or three catgut stitches are then finished and the two ends of the catgut tied together.

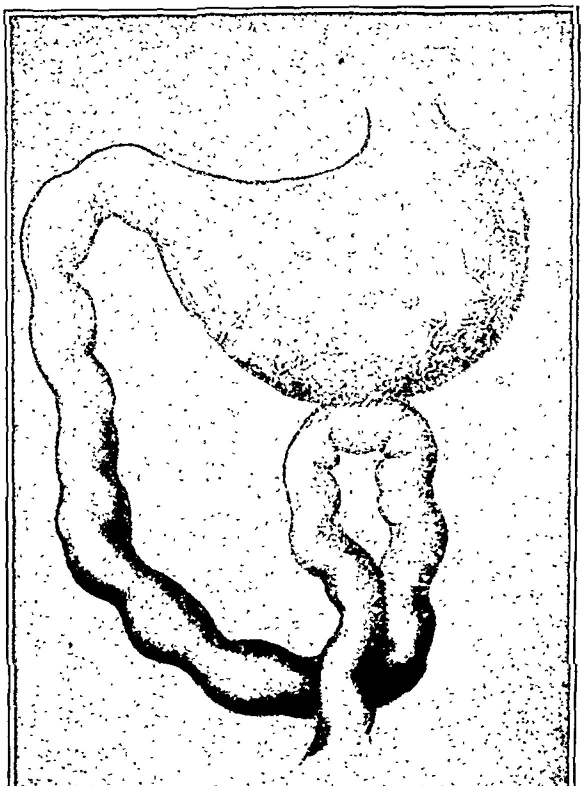

Fig. 7.—Diagram of the anastomosis completed. The intestinal anastomosis is performed in exactly the same manner as gastro-enterostomy.

Case 4.—Mr. S., 51 years old. Symptoms of pyloric stenosis and dilatation for many years. About six years before the operation I taught the patient to use the stomach tube with which he got along for awhile. He finally came back asking for relief from the fearful vomiting which kept him awake nearly every night. No palpable tumor. Somewhat anemic but not cachectic. Operation revealed a very dilated stomach with a moderate degree of pyloric stenosis. No malignant tumor. Anterior gastro-enterostomy and entero-anastomosis with my instrument. Perfect recovery. Has several times afterwards reported that he is in perfect health and follows his occupation as a farmer.

Case 5.—Mrs. O., 43 years old. Symptoms of cancer of the stomach, with pyloric stenosis. Large palpable tumor. Nearly constant vomiting. Utterly anemic and poor. Although an operation was described to her in a very unfavorable light she wished to undergo the same as a means to get relief in one way or the other. Anterior gastro-enterostomy and entero-anastomosis with my instrument, after having seen the impossibility to remove all cancerous metastases. Complete relief from all gastric symptoms and she left the hospital three weeks after the operation more grateful than any patient I ever saw before. Some time after she had left the hospital I heard that she was feeling well and relishing nearly all kinds of food.

Case 6.—Mrs. S., 43 years old. Symptoms of pyloric stenosis and palpable tumor in epigastrium. Diagnosis: pyloric cancer. Wished to be operated on to get relief. Operation revealed a pyloric cancer, making resection impossible on account of numerous metastases. Anterior gastro-enterostomy and entero-anastomosis. Complete relief from gastric symptoms. Latest news from her, about six weeks after the operation, reports everything all right.

CONCLUSIONS.

Any kind of lateral anastomosis is rapidly performed, about one-half hour being generally sufficient. The size of the anastomosis opening can be made larger or smaller, as the need may be, by pushing the blades more or less deeply into the bowel before the forceps are locked. Leakage of visceral contents during the operation is, with ordinary care, nearly impossible.

With the instrument in the bowel the sewing can be done with ease very rapidly and substantially. It leaves no foreign body in the bowel to be expelled afterwards. A surgeon with limited experience in intestinal work can, with this instrument, perform lateral anastomosis with comparative safety.

Post-operative hemorrhage from the stomach is prevented by crushing of the tissues with the forceps, by the suturing and the cauterization of the cut edges. No hemorrhage has so far occurred in any of my cases.

ETIOLOGY AND TREATMENT OF CHRONIC CYSTITIS.

A. C. STOKES, B.S., M.D.
Professor Genito-Urinary Surgery, Medical Department, University of Nebraska.
OMAHA.

Comparatively little work has been done in the last ten years on the scientific investigation of cystitis. Some, however, has been done which is very valuable, and from it I shall take the liberty of drawing very freely.

ETIOLOGY.

The etiology of cystitis is essentially a bacteriological problem. The germs most frequently found are, in order of frequency, colon bacillus, streptococcus, staphylococcus in several species, typhoid bacillus, gonococcus of Neisser, proteus vulgaris and the tubercle bacillus. The fermentation of the urine has been shown by Melchior and Muller to be rather a result of infection than a cause of cystitis, certain germs producing ammonium carbonate from urea, thus converting the urine into an ammoniacal substance, giving an alkaline reaction. The chief germs which do so are the micrococcus of urea, species of the pyogenic germs, and occasionally the colon bacillus and *Proteus vulgaris*. It will be found in a goodly number of cases—perhaps one-half—that the urine is acid and we may still have the evidences of cystitis present. In most text-books is found the statement that in chronic cystitis the reaction of urine is alkaline. Melchior's work develops that a great majority of cases of chronic cystitis are acid. Robert Tyler[1] says that "in the majority of cases urine is acid." Brown[2] of Baltimore says "contrary to the opinions expressed in the majority of text-books, a great majority of the infections of both bladder and kidney are associated with acidity of urine—i. e., are due to micrococci, which do not split up the urea." Young[3] of Baltimore holds the same opinion.

In our own experience in sixteen cases of chronic cystitis we have found the urine to give an acid reaction in ten cases and alkaline in the others. Rovsing[4] in thirty cases found only three acid and the remaining alkaline. The gonococcus, the bacillus of tuberculosis, the colon and bacillus all seem to develop and grow best in an acid urine. It is, therefore, a plain fact that since in cystitis we have various infections, it is well to study with care the bacteriologic reactions in each separate infection and the character of treatment which is most often of value to a particular infection. Before treating a case of chronic cystitis I should desire to know the reaction of the urine and the principal germ present. Occasionally there may be several infections at the same time. However, one is usually predominant and, I think, by ordinary plate growths, it can be readily segregated.

We must not forget, however, the other side of the problem, viz.: That we can have the bladder subject constantly to infection and still have no cystitis present. The urine is the avenue for excretion of many forms of infection from the tissues of the body. It is only a perfectly aseptic fluid when it is perfectly normal, and it is perhaps rare that it is perfectly normal, so that the bladder is constantly subjected to infections of all kinds, but only occasionally does the infection lodge. It is difficult for a germ to lodge and grow on the squamous epithelial cell of the fundus of the bladder and also nearly as difficult on the transitional cells of the base of the bladder. We must, therefore, have other abnormal conditions present besides the actual presence of germs.

Reymond[5] has shown that an infection may travel from the tubes and uterus and develop a cystitis. Melchior has demonstrated that they may pass from the rectum through the bowel and cause a cystitis. The presence of foreign bodies, as is well known, may cause a cystitis, e. g., stone; retention of urine as behind an enlarged prostate; a bladder which is poorly nourished; certain spinal diseases, blows, falls and injuries in the region of the bladder, all have a predisposing influence toward the production of cystitis, but these may exist and without germs we will not have cystitis. Germs may enter the bladder in several ways: *a*, from the kidneys; *b*, urethra; *c*, by unclean instruments; *d*, from tubes, uterus and rectum; *e*, by the blood; *f*, by the lymphatics.

3. Johns Hopkins Bulletin, January, 1901.
4. Blasen-Entzündüngen, Berlin, 1890.
5. Annales Mal. des Organ, 9, April, 1893.

Dividing the etiology of cystitis for purposes of description into predisposing and exciting causes, we have as exciting causes the various germs above mentioned, and as predisposing causes the mechanical and chemical irritations above tabulated.

TREATMENT.

In treating all cases of chronic cystitis we must first consider the predisposing cause or causes. If the predisposing cause is extravesical in the beginning it is hard to cure it by intravesical treatment. The external cause must be carefully considered. If we find a prolapsed bladder or an enlarged prostate we can not hope to permanently cure the resulting cystitis unless the condition producing it is removed. Belfield always claims cystitis to be only a symptom of some other disorder. This is a very good point to consider. But, when the infection once has gained a hold in a bladder it is necessary that it should be treated itself, even though the predisposing cause may have been removed, for the infection in a bladder having obtained, it is as resistant to limitation or cure as it was difficult to gain a hold in the first place.

The treatment may then be classified under the following heads: *a*, internal medication; *b*, washing bladder; *c*, instillation into bladder; *d*, topical application; *e*, stretching bladder (Young); *f*, operation.

The character of the medication must depend upon the reaction of the urine. If it is acid, a drug converting urine into an alkaline reaction is called for. Urotropin and benzoic acid are the best form of drugs for a cystitis which gives an alkaline urine, and are of very little value in a case where the urine is already acid. It is a fairly good rule to follow that if a germ lives and flourishes in an acid medium, its growth will be retarded, if not destroyed, in alkaline media, and vice versa. On this theory we must proceed in internal medication for chronic cystitis. We have not time to discuss in detail the different remedies and their use, only to condemn the indiscriminate use of urotropin in all forms of cystitis. It should be used only in those cases producing alkaline urine. Locally, it has been our custom to proceed as follows: An infected bladder is washed out with a saturated solution of boric acid until the solution returns clear. This may be done through a return current catheter. But if this can not be introduced without pain, as over an hypertrophied prostate, a rubber catheter or lisle thread catheter may be used. The latter is often the best. Fill up the bladder under hydraulic pressure of about two or three feet, until it is painful. Repeat several times until the fluid returns clear. In the cystitis of gonorrheal or pyogenic origin we then instill into the bladder a 1 to 5000 silver nitrate solution about once in three days and in bulk about 30 c.c., increasing the strength until it becomes too irritating, reaching a strength of 1 to 200 in some cases.

In infections from the colon and tubercle bacilli we have found mercuric chlorid to be a very efficient remedy to instill into a bladder which has been washed out clean by some good antiseptic. We use about 30 c.c. of a 1 to 20,000 solution, putting it into the bladder once in two or three days as the irritation seems to allow, gradually increasing in strength. This should never be used in gonorrheal cystitis nor silver nitrate in the tubercular form. In tubercular cystitis we have often obtained good results from instillation of about two drams of a 10 per cent. solution of iodoform in glycerin, used in the same manner as above. We would not recommend the use of potassium permanganate in any case in the bladder. If this method does not succeed we proceed to drain by surgical interference.

Perineal drainage is generally superior to suprapubic drainage in all cases except it be for the presence of a stone or some foreign body which can not be removed by the perineal route. In woman it is rarely necessary to drain the bladder, but when necessary it can be done through the anterior vaginal wall. Then by good drainage and the usual washings and hygienic after-treatment and perfect rest when possible, we can hope for good results.

The purpose of this paper is, therefore, to impress the value of a careful consideration of the bacteriology of chronic cystitis, and to urge a rational treatment for the same.

Clinical Report.

A UNIQUE CASE OF VESICAL CALCULUS.

Major D. C. HUFFMAN,
SURGEON, CENTRAL BRANCH, N. H. D.V.S.
AND
F. W. ROUSH, M.D.
ASSISTANT-SURGEON, NATIONAL MILITARY HOME, OHIO.

James Trimble, Co. D, 63d Pennsylvania, aged 62 years, says he was wounded at the second battle of Bull Run, Aug. 29, 1862, while in a kneeling posture, by a ball which entered the inner side of the left thigh about five inches below the groin. A puckering cicatrix verifies his statement. He says he was treated in the army hospital, where futile efforts were made to locate the ball; that the wound healed uninterruptedly, and that he was soon enjoying his usual good health.

During January, 1902, he commenced to have vesical derangement and was troubled more or less until July 30, 1902, when he was admitted to hospital with retention of urine. An attempt to catheterize him was made, but was unsuccessful; the catheter could not be passed beyond the prostatic portion of the urethra, where it met a hard resisting substance. On palpation, a hard tumor about the size of a walnut could be outlined at the base of the penis.

A diagnosis of vesical calculus was made and lithotomy decided on. Suprapubic lithotomy was performed July 31 and a calculus with a flattened lead musket ball nucleus was removed. Considerable difficulty was experienced in removing the calculus, as it was encysted in a cul-de-sac near the neck of the bladder. It could not be removed with stone forceps and had to be extricated by introducing the fingers into the bladder. When the calculus was extricated a considerable quantity of pus was liberated from an abscess cavity which had formed at the left side of the calculus. The calculus and ball weighed 580 grains.

When did the ball enter the bladder? It probably was not in the cavity of the bladder prior to the beginning of the trouble in January, for up to that time he had had no symptoms indicating its presence. It could not have penetrated the bladder wall at the time of receiving the wound, or there would have been an extravasation of urine into the pelvic cavity with dire results.

The rational conclusion is that the ball began its passage through the bladder wall at the time of the appearance of the first vesical symptoms in January and succeeded in penetrating the wall by the slow process of ulcerative absorption.

At the time of the operation, the patient was somewhat weak and emaciated, but withstood the operation very well.

This case is unique in that the time intervening between the reception of the wound and the presentation of the symptoms was forty years.

Physicians and Politicians.—If medical men paid more attention to politics politicians would pay more attention to medical men's interests.—*Alienist and Neurologist.*

SATURDAY, SEPTEMBER 27, 1902.

EPILEPSY AND RESPONSIBILITY.

As our knowledge of nervous and mental diseases has developed there has come the realization that the present popular state of feeling as to intentional malicious actions, and especially the interpretation and application of the laws with regard to crime, must undergo a decided modification, if a system of injustice in the name of right is not to be perpetuated and serious wrong done with short-sighted good intentions. This has become manifest in nothing more perhaps than in the gradual evolution of our knowledge of epilepsy. The generally accepted ideas as to the criterion of right and wrong in others' actions fall before the observed anomalies as to moral responsibility occurring in this protean disease, for the study of which modern life is providing so many opportunities that fortunately are not being neglected by our generation. From it come some of the most valuable practical lessons of modern psychiatry. Hundreds of years of study of free will in the abstract have not given so much real knowledge on this subject as the last twenty years of careful observation of the phenomena of conduct in connection with the varying diseased mental states of the epileptic. Here, as in so many other departments of anthropology, pathology has stepped in to supplement the knowledge gained from supposedly more positive sources, and has supplied a key to at least part of the mystery that was so shrouded in obscurity before.

The change of thought on this important subject has come so quietly that many of us are hardly aware of it. It constitutes, however, one of the most practically important features of modern medical progress, especially as on medical men must devolve the propaganda of the newer ideas in order that they may produce their due impression in the minds of our generation and be reflected in our legislation and the interpretation of existing laws. The legal standard of criminal responsibility so often judicially assumed even at the present time is that the knowledge of the distinction between right and wrong constitutes the essence of punishable malice when materially criminal acts are committed. This old-time criterion must give way before the declarations of psychiatrists, that the intelligence of epileptics may be unimpaired, yet the emotions and volitions be so disturbed as to be at times beyond the patient's control.

In an article[1] on epilepsy and its relation to crime, read before the Rochester Academy of Medicine, Dr. William P. Spratling illustrates by selected cases the fact that it is not the continuously insane epileptic that is liable to commit crime, but the patient who has long, perfectly lucid and responsible intervals, that may at any time, however, be interrupted by the irresponsible phase of the disease, yet without the slightest preliminary symptomatic warning to betray it. When the attacks of epilepsy, instead of being of the classic motor type, are what is known as "psychical epilepsy" or the "psychical epileptic equivalent," then the appreciation of the amount of the responsibility involved in a given act becomes one of the most difficult problems with which the alienist has to deal. Spratling does not hesitate to declare that established proof of the presence of the psychical epileptic equivalent ought to settle the absence of responsibility beyond reasonable doubt. When we consider that epilepsy must have a beginning, that it sometimes only asserts itself late in life, that not infrequently, until some great emotional strain calls out an exaggerated exhibition of the stigmata of the neurosis, it may have produced symptoms so slight as to escape the notice of any but a most expert observer in such matters, it can be seen how cautiously judgments as to responsibility must be made. How many people there are who have queer moods into which even friends do not inquire too closely. The intricacy of this problem of moral responsibility takes on additional difficulty of solution as progress of knowledge shows the increased possibilities of imperative or uncontrolled pathologic conditions assuming sway over the individual in the midst of apparent mental health.

The opinions thus expressed are an echo of what psychiatrists have been insisting on for some time. Kraepelin may be taken as the representative of progressive German psychiatry in this matter. His opinion as stated by Defendorf[2] is that "in more than half the cases (of epilepsy) intellectual activity is impaired, though proportionally to a less degree than the emotions or volitions." In a word, there is a distinct tendency to that moral insanity whose independent occurrence has often been disputed. This renders accountability almost minimal in many cases, and its recognition would do away with most of the false legal maxims that now unfortunately hamper the true course of justice.

Many of the ideas that are now confined to specialists in mental diseases will have to become common property before a change in the legal status of the irresponsible can be looked for. It is the plain duty of medical men generally to see that proper notions on these subjects become widespread in order to lead up to such modification of present-day persuasions as will be worthy of the stage of culture of our generation.

THE UNHEALTHFUL LONG SKIRT.

The German correspondent of the *Medical Press and Circular* in a recent issue tells of a Teutonic crusade against the corset and the trailing skirt, which he considers has, like the French anti-alcohol agitation, come to stay. It is encouraging to learn this, for it is not long since that we heard that in German society it was considered almost immodest for a woman to dispense with the corset. It seemed to be considered a sort of defensive armor against masculine arms. The corset has long been under medical condemnation; and we do not believe that the women of the present day suffer so severely from its effects as did their ancestresses, though the fashion-plate ideals are bad enough yet. It can even be considered in some special cases and in some of its modifications as having a utility, but it is hard to find how to say a good word for the trailing skirt. Indoors it is a somewhat perilous sacrifice of hygiene to conventional esthetics, but on the street it is in every sense an abomination. With the old-fashioned way of letting it sweep the sidewalks and crossings its untidiness was alone enough, one would think, to disgust women into its disuse. At the present time it is more the fashion to occupy one hand in holding it up behind, a very ineffectual method of securing either cleanliness or hygienic safety, and certainly inconvenient enough it would appear. Moreover, the bodily twisting it requires tends to produce deformity and should the practice continue long enough we may expect to see the female half or more of our species become generally one-sided, with hypertrophied latissimi dorsi and spinal curvature. No man, or woman either, can complacently anticipate such a result: and, moreover, there is nothing really becoming or graceful in the practice, but rather the reverse. It seems as if it might be an effect of a dissemination of a knowledge of the germ theory of disease, and perhaps we may hope that a spread of information as to the deforming possibilities of the present popular custom will be the last straw that will break the camel's back of fashionable slavery to the trailing or posteriorly uplifted skirt.

---

[1] Journal of Nervous and Mental Diseases, August, 1902, p. 481.

[2] "Clinical Psychiatry," A. Ross Defendorf. Macmillan Co. 1902.

Esthetically as well as hygienically the abbreviated walking skirt is far ahead, and this fact appears to have been appreciated in one, at least, of the two national dressmakers' conventions lately in session. It is hardly to be expected that health-considerations simply as such would carry things in such a body. A plea was made for the short petticoat, and perhaps in our ignorance we assume that this implies or includes also more brevity of the outer lower garment, on the ground of its conducing to greater gracefulness in walking. Our opinion on this point is sufficiently made clear by what has been said. and we believe most of the male sex share it: it is therefore some satisfaction to find that the professional or commercial arbiters of fashion are of a similar mind.

Of course. to us professionally the health considerations are first. but we are glad to recognize any aid that may be available for the good cause. Anything that will make less urgent the perennial cry for reform in woman's dress. especially as regards the trailing skirt, ought to be most welcome.

DISCRIMINATION IN PHYSICAL CULTURE METHODS.

The large amount of expensive advertising which is done nowadays by the propagators of various physical culture systems betokens a patronage considerable enough to pay for the outlay and probably a handsome profit besides. Considering the fact that the teachers of these various systems, either by personal direction or by correspondence, set individuals at vigorous physical training which often has no relation to the person's peculiarities or physiologic needs, it follows that not a little harm may be done, and that, therefore, the subject merits the attention of physicians who may sometimes be consulted in the matter.

It is one thing to say, as a general statement, that people do not exercise enough, but it is quite a different matter to start them on the task of building their muscular system after the model of the athletes whose pictures appear so regularly in the advertising pages of our magazines. Exercise certainly is desirable for the furtherance of active metabolism, of good repair and excretion of waste materials, but large muscles in this day and generation serve little purpose indeed. In developing an exaggerated muscular system it is quite possible to sap the vitality. Men of experience in physical training not rarely see individuals with large muscles well used and yet with poor general health. And large muscles, once obtained, must be lived up to or else, like other unused organs, by their very existence they will render one more prone to disease.

Another point open to criticism is the method itself by which is taught the attainment of athletic proportions. The much advertised systems of working without gymnastic apparatus amount largely to the scheme of offering resistance to one set of muscles by the contraction of an antagonistic set. As Dr Sargent, the well-known head of the Harvard School of Physical Training, writes in a letter, this "is anything but physiologic. How to relax antagonistic muscles, not how to contract them, is the desideratum." Whether we are desirous of attaining greater facility in the use of any given muscles or whether we are aiming at the better metabolism which increased circulation of blood and lymph brings, this statement of Sargent's seems obviously true. Then, too. the get-strong-quick phase of these advertised methods must necessarily result in the acquiring of impermanent strength and surely cause a harmful strain on any circulatory apparatus unaccustomed to much physical exertion. We do not hesitate to say that harm will be done by the methods of directing exercise on the basis of muscle measurements, especially when this exercise is taken indoors.

However, it must be confessed that through these advertised "systems" there has been aroused much popular enthusiasm for exercise among the men and women who need it most, and this of itself is good. The subject has been too little touched on by the most competent authorities in ways that might help to form safe opinions for both physician and laity.

REGULATION OF VENEREAL DISEASE.

We present this week a portion of the proceedings of the *International Conference for the Prevention of Syphilis and Venereal Disease*, recently held at Brussels, and the report will be completed in our next issue. As perhaps might have been expected, no very definite statement of policy was agreed on; the differences of opinion were not less marked than at the earlier congress three years ago. It is evident that absolute agreement as regards the questions of regulation of prostitution is still far off, and that neither this congress nor perhaps many future ones will end the discussion.

The agitation of moral questions will never be successfully suppressed, and as the world progresses they are becoming still more important factors in our civilization. There is one here involved that will not be readily downed, and which—even if regulation were an unqualified success, which admittedly it is not—would still arise to trouble its advocates. Some legal measures do seem possible, however, and it may be that both sides may yet come together in regard to some points of public prophylaxis. For example, the notification of venereal disease and the application of legal penalties for communicating disease to innocent parties are practicable to a certain extent and should be enforced.

It seems a question to us, in spite of the opinions favored in the conference, whether the ordinary restrictions of medical secrecy should apply to their full extent in case of venereal disease; at least it should be *permissible to warn innocent victims against exposure.* It does also appear that some practical police regulation and sanitation without any legal recognition of the evil might be possible and have some good effect in seaports and in connection with military garrisons, and that this might be made compatible with earnest effort to suppress it as far as possible.

Nothing should be done that will encourage a feeling of safety in immorality, and here comes the difficulty in the case. In fact, the difficulties multiply with the consideration of the conditions, and the position of the abolitionists of no compromise with the evil is really the only consistently logical one after all, whatever one may think of its practical application. There is no question, of course, as to the value of moral and educational measures, and in these we have our greatest hopes. Whatever is done should not be such as would in any way lower our moral ideals. No community is ever better than its ideal, and the lower this ideal the more probable is its moral degradation.

NASAL THERAPY FOR DYSMENORRHEA.

Five years ago Fliess published a monograph on the connection between nasal and menstrual conditions, the main thesis being that in the nose there are two "genital spots," one the tuberculum septi and the other on the inferior turbinated, which in many women show congestion and sensitiveness during menstruation. In some cases of severe dysmenorrhea Fliess found he was able to control the pain by application of cocain to these "spots," and more rarely he permanently cured the menstrual difficulty by cauterization of the same region.

The idea of relationship between the upper respiratory tract and the genital organs in woman is much older than the contribution by Fliess. Bleeding from the nose and pharynx during menstruation has often been noted, and the same periodic phenomenon has been recorded in cases of amenorrhea caused by pregnancy, the menopause, or pathologic conditions. Since the publication by Fliess of his findings the subject has been discussed at length in some Continental medical societies and has been reported on by a number of clinicians, all of whom seem to find a certain percentage of cases amenable to this treatment. Schiff found cocain effective in 35 out of 41 cases, and concluded that it was of service in those cases where the pain persists after the flow is well established. Koblanck, Ruge, Knorr and Krönig have all reported series of cases favorably affected. More lately Ephraim[1] has been successful in arresting the pain of intense dysmenorrhea in 18 out of 24 cases treated by cocain. In Amann's clinic Linder[2] has been studying this subject for the last two years on a series of 30 cases. The relief from pain has been so marked that some of the patients have returned to have other painful disorders treated.

The influence of suggestion in rendering this treatment effective has been discussed time and again and proves a difficult question to decide. Schiff carefully undertook to rule out this factor and found that applications of water were ineffective. Linder reports a special series of 16 cases selected with great care in order to test more exactly this nasal therapy. In 10 of these cocain caused cessation of pain, sometimes lasting 24 hours. When the pain had returned Linder tried a second application, this time secretly substituting plain water for the cocain solution. Two of the 10 were again favorably affected. Repetition of the cocain treatment then proved effective in all cases. Linder is forced to think that in some instances suggestion is the strongest factor in the result, although it must be remembered that even water causes physiologic effect on the nasal mucous membrane. For him the question of a nasal dysmenorrhea remains *in suspensio,* but the striking number of cases which are relieved by nasal therapy, which is harmless whether or not it involves suggestion, recommends a method which ought to be equally welcome to physician and patient for the treatment of such an obstinate disorder. The cocain is applied on a pledget of cotton through a speculum, 2 or 3 drops of a 10-20 per cent. solution, and is carefully limited to the "genital spots," so that there is no danger of intoxication. To be effective it may have to be repeated in 15 minutes. The cessation of pain, even if for only overnight, is extremely grateful to the patient. Cauteriza-

2. Münchener Med. Wochenschrift, June 3, 1902.

tion, in the experience of several men, permanently cures far fewer cases of dysmenorrhea than cocain temporarily relieves.

ANOTHER STATE SOCIETY JOURNAL.

At its last annual session the Michigan State Medical Society decided to replace the annual transactions by a monthly journal. The initial number is before us, bearing the title of "The Journal of the Michigan State Medical Society," and is a credit to the society and to the officers who have the journal in charge. There are thirty-six reading and twelve advertising pages. Dr. A. P. Biddle, the efficient secretary of the society, is the editor.

DISINFECTION VS. VACCINATION.

Last February the health officer of the city of Cleveland published his account of "How Cleveland was Rid of Smallpox," a paper that has attracted considerable attention, especially among the laity (it was published in a popular magazine as well as in a medical journal), on account of its apparent magnification of the value of disinfection in the prophylaxis of this disease. The Journal has already noticed[1] the sanitary misconceptions to which it gave rise, and more recently the Ohio State Board of Health, in its August-September bulletin, takes up the subject and shows how really inefficient the disinfection procedures were. The *Cleveland Medical Journal* for September also takes up the question, speaking with the authority of one on the ground, and shows that the local epidemic was practically at an end when the present health officer went into office. He simply gave the corpse a kick by this showing and his claims for the efficiency of disinfection. The stir that has been made over it by the anti-vaccinationists has about as much basis as that on the utterly fictitious data they sometimes use. The subsequent recrudescence of smallpox in Cleveland in spite of disinfection ought to be an object lesson, but, of course, it will weigh nothing with the extremists who will still parade Dr. Friedrich's antisepsis as a conclusive evidence that smallpox is only a filth disease and vaccination a failure. It is to be very much regretted that the Cleveland health officer does not more explicitly repudiate any intention to overvalue disinfection at the expense of vaccination; his (unsigned) letter to the secretary of the State Board of Health, while it is practically a surrender of any special claims, yet has the appearance of avoidance of direct statement to that effect. The whole affair is an unfortunate one for him and he ought to spare no pains to correct the false impressions his imprudent publication has created.

MALIGNANT DISEASE OF THE VERMIFORM APPENDIX.

It will not be denied that the one certain means of preventing recurrence of appendicitis is removal of the offending organ. There are still a considerable number of practitioners, however, who adhere to medicinal treatment for the attacks, but who also realize that recurrence may take place at any time. The difficulty of the situation and the danger from nonsurgical intervention resides in the fact that no one can determine in advance the nature of an attack and its mode of termination, so that the vast majority of clinicians have come to believe that the risk of operation is to be preferred to the uncertainty of outcome without surgical intervention. An additional factor that must be taken into consideration in this connection is pointed out by Drs. R. H. Harte and R. N. Willson,[1] namely, the possibility of malignant disease of the appendix giving rise to symptoms of inflammation of that organ. They report two cases of this character in which the disease was limited to the appendix, and refer to 16 others of the same kind, collected from the literature, and also to others in which, while the appendix was the primary seat of the disease, extension had taken place to adjacent tissues. All of the cases in which it appeared probable that the disease was limited to the appendix presented the symptoms of ordinary relapsing appendicitis, but in none was the true state of affairs suspected. In some a small tumor was present, but this was mistaken for a concretion in the lumen of the appendix until the latter was laid open. In others there was no macroscopic evidence of new growth. In one there was extensive suppuration with adhesions and a perforation in the appendix. Existing statistical evidence tends to show that malignant disease of the vermiform appendix is rare, but the large majority of the cases have been reported within recent times, so that it may be inferred that the disorder will be detected with greater frequency as the practice becomes more common of examining histologically appendices removed at operation or after death. In explanation of the formation it is suggested that it is the result of a primary inflammation long present and semi-quiescent, but breaking down the resisting power of the tissues in connection with some unusual disturbance in the general or local nutrition.

INTRAVENOUS INJECTIONS IN RABIES.

At the present time no one fully informed and free from prejudice doubts the efficacy of the Pasteur treatment for rabies. In the Pasteur Institute in Paris the number of deaths of the cases treated during the past fifteen years has been less than 1 per cent. For the year 1901 there were five deaths in 1,321 cases treated, that is, a mortality of 0.38 per cent. It is acceded by those especially interested that a more intensive method of treatment than the present is highly desirable in order to avoid the rare failures, and in order, if possible, to achieve better success than now in the cases which come under treatment a long time after the infection. Recently Krasmitski[2] has experimented with the intravenous injection of the virus of rabies used for immunization. He finds that such injections are not especially dangerous, provided that the virus is in emulsion, filtered and well diluted, and that the fluid is heated to 37 degrees. Such intravenous injections produce a more substantial immunity more rapidly than the usual means of vaccination. In the rabbit, for instance, which is the most susceptible animal, such injections may prevent death from intracranial inoculation of the virus which is otherwise always fatal. Experiments have been made also on human persons bitten by rabid animals, especially in grave cases. These experiments showed the harmlessness of the method in man and also an apparent increased efficacy. On the whole, the results seem to be distinctly encouraging, but further work and observation are necessary in order to determine the exact value of this new form of Pasteur treatment. During the summer months especially cases of fatal hydrophobia are not rare in our cities and elsewhere. These are cases that from neglect or ignorance or inability have failed to avail themselves of the opportunities offered for Pasteur treatment by various institutions in this country. No doubt a thorough study of the occurrence of hydrophobia in the United States and its fatality would reveal that the disease is more frequent and more destructive of human life than we have believed or realized. In a country so large and so rich as this there ought to be established several institutes of a public character for the treatment of rabies. France now has half a dozen such institutes scattered in various centers. The private institutions now existing in this country are doing good work no doubt, but it would hardly be expected that they should reach the highest degree of scientific efficiency without direct financial support, either by the state or by endowment. Furthermore, some sort of propaganda should be started from time to time in order to keep alive among the people the fact that after bites by animals supposed to be rabid or actually rabid safety only lies in prompt resort to the Pasteur treatment.

Medical News.

COLORADO.

Mortality.—During August 836 deaths were reported in the state, a mortality of 17.14 per 1000 per annum. Typhoid fever caused 51 deaths, diphtheria 17, and scarlet fever 2.

Typhoid Increase.—Colorado had 644 cases of typhoid fever in August, an increase of 415 over the previous month. Denver had 148 cases and Arapahoe County a total of 156 cases.

Personal.—Dr. A. A. Blackman has returned to Colorado Springs, after a visit of two months in Japan.——Dr. Claude E. Cooper, Denver, has been appointed a member of the State Board of Health, vice Dr. George E. Tyler, deceased.

Millions for the Sick.—By the will of the late W. S. Stratton $1,000,000 is left to build the Myron Stratton Home for Sick Persons in Colorado Springs, and the balance of the estate, after payment of bequests, is to be used for the maintenance of the institution.

ILLINOIS.

A Western Bloomingdale.—It is announced that Dr. Henry J. Brooks, after several years of arduous labor, has succeeded in interesting capitalists and physicians in the establishment of a great hospital for the insane, modeled on the lines of that at Bloomingdale, N. Y. A large sum is said to have been pledged and several prominent alienists of Chicago have expressed their approval of the scheme. The profits are to be devoted to the care of indigent patients.

Personal.—Dr. William G. Bechtold, Breese, had a peculiar accident, September 10, whereby he lost the terminal phalanx of his right forefinger. He was sponging his horse's mouth, when the animal sneezed, closing his teeth over the doctor's finger, completely severing it.——A farewell dinner was given by twenty physicians of Champaign and Urbana, on September 19, to Dr. J. Ora Pearman, who is about to move from Champaign to Mahomet.——Dr. Everett H. Butterfield, Ottawa, has been re-elected physician of La Salle County.——Dr. and Mrs. Frank J. Mittan, Colfax, who are about to move to California, were presented by their friends in Colfax with a set of solid silver spoons, knives and forks, September 10.

Chicago.

Midwife Fined for Practicing Medicine.—Mrs. Paulina Taeschler, a midwife, was fined $200 by a jury in Justice Everett's court, September 18, for practicing medicine without a license. The woman operated a private maternity.

Personal.—Dr. Thomas A. Woodruff, editorial secretary of the *Ophthalmic Record*, has been elected professor of ophthalmology in the Chicago Eye, Ear, Nose and Throat College.——Dr. and Mrs. Albert B. Hale have returned after a summer abroad.

Illinois Medical College Commencement.—The annual commencement exercises of this college were held at Handel Hall, September 25, a graduating class of 34 receiving diplomas. The doctorate address was delivered by Judge John Barton Payne. The annual banquet took place at the Auditorium Hotel in the evening.

Transferred to University.—The College of Physicians and Surgeons, now the medical department of the University of Illinois, has conveyed to the latter the old West Division High School property at Ogden avenue and Congress Street, which it acquired from the city last year. The consideration named in the transfer was the same as in the deed from the city, $186,000.

Typhoid Decreasing.—The typhoid mortality has fallen from 10.5 per cent. of the total mortality during the first week of September to 7.8 per cent. last week. The typhoid deaths for the three weeks of the month have been 55, 43 and 38 respectively, and although there were 18 more cases in the County Hospital at the close of the week, there is every reason to believe that, if the precautions so generally enforced during the past six weeks be continued until cold weather sets in, there will be nothing more than the usual seasonal increase of the disease during the remainder of the fall.

Comparative Mortality.—The 487 deaths from all causes reported during the week ended September 20, represent a yearly mortality of 13.83 per 1000 of population, as compared with 14.13 the week previous and 12.68 in the corresponding week of 1901. The excess, as compared with last year, was chiefly from chronic diseases unfavorably affected by low temperature. Thus Bright's disease carried off 25 victims, or nearly double the number (14) in 1901; consumption 76, as against 33; pneumonia 43, as against 32; from the same cause the deaths among the aged were also increased—92 deaths of those over 60 years last week, and 76 in the corresponding week of last year.

Alpha Omega Alpha Society.—Very recently there has been organized in the senior class of the College of Physicians and Surgeons what the organizers believe to be the first honorary society in a medical school in this country. It embodies features not unlike the Phi Beta Kappa Society in literary colleges. It resembles much more closely, however, the Skull and Bones Society of Yale because of the high general standard required. Not more than 15 juniors will be elected to membership, and the remainder to be chosen out of that class will be elected by these members in their senior year. Not more than 30 names are to be considered for election from any one class of over 200 students, and the proportion can never exceed one-sixth of the class. The constitution will allow chapters in other medical colleges of the highest standing only, and honorary members may be admitted, who shall in every case, be men or women eminent in the profession. The object of this fraternity is to maintain a high standard of thought and action in medical schools and in the profession, and to endeavor to encourage the high ideals supported by earnest students and practitioners everywhere.

MARYLAND.

Baltimore's Deaths.—For the week ended September 20, the deaths were 193. The typhoid deaths numbered 9, the same as last week, but only 71 new cases of this disease were reported. Consumption increased in mortality to 31, and pneumonia to 11.

Alleged Abortionist Imprisoned.—Dr. William B. Hawkins, who forfeited his bail by failing to appear for trial last February on the charge of causing the death of a woman here by criminal operation, was arrested September 18, in Philadelphia, and is in jail in Baltimore.

New Sanatoria.—Drs. George W. Todd and J. McFadden Dick have formed a stock company for the purpose of building a sanatorium at Salisbury, opposite the Peninsula General Hospital. This is the first institution of the sort on the eastern shore of Maryland.——The Maryland Quarter Club has collected $2300 towards the erection of a sanatorium in the mountains of Maryland for the treatment of consumptive patients.

Personals.—Dr. Howard A. Kelly has given $10,000 for the extension of the gynecologic ward of the Johns Hopkins Hospital.——Dr. J. L. Truax has gone on a trip to Newfoundland.——Dr. J. W. C. Cuddy has been appointed clinical professor of dermatology in the Baltimore University.——Drs. George J. Preston, R. B. Warfield and John H. Grimes have returned from Europe.——The Health Commissioner has appointed Dr. Albert D. Driscoll one of the health wardens.

May Start Laboratory.—Dr. Franklin P. Mall, professor of anatomy in the Johns Hopkins Medical School, Baltimore, has returned from New England where he passed the summer. During most of his vacation he was busy with professional studies on the island of Little Chebeague, in Casco Bay, where he devoted himself to study of the human embryo and investigation of the habitat of the salt-water clam. His discoveries in the latter direction are said to have a commercial bearing. Other Hopkins men who go to the same place are Drs. Harmon Morse, professor of chemistry; W. H. Howell, professor of physiology, and R. G. Harrison, associate professor of anatomy. The congregation of so many Hopkins men at one place has suggested to them the erection of a small laboratory on the island of Great Chebeague for private research during the hot weather.

MISSOURI.

Medical Students Dine.—About 150 students of the Kansas City Medical College were guests at a dinner given by the faculty, September 16, in honor of the opening of the college year.

Personal.—Dr. William H. Mayfield, St. Louis, has been in Colorado Springs, endeavoring to secure a site for a sanatorium for consumptives, to be established under the auspices of the Saturday and Sunday Hospital Society of St. Louis.——Dr. Samuel H. Headlee, St. James, celebrated his semi-centenary in medicine, September 2.

Proposes Permanent Hospital.—Dr. Leonidas H. Laidley, medical director of the Louisiana Purchase Exposition, offers the suggestion that the Stillman Infirmary idea be used in the building of the Exposition Hospital. He believes that some philanthropist might be found who would aid the plan so that the hospital could be made permanent, with its endowment, to carry out the plan of the Stillman Infirmary for sick students attending Washington University. The suggestion carries with it the inference that the World's Fair Hospital would be erected on the Washington University tract of the Exposition site, remaining there after as a corporate part of the university ground.

Levering Hospital Staff.—The medical staff of Levering Hospital, Hannibal, held a meeting September 9, and organized by the election of the following officers: President, Dr. John N. Baskett; secretary, Dr. F. Janet Reid. The following assignments were made: Consulting physicians, Drs. Stephen G. Smith, and Richard Schmidt; attending surgeon, Dr. Thomas C. Chowning; consulting surgeons, Drs. Henry L. Banks, and John J. Bourn; attending obstetrician, Dr. Henry L. Banks; consulting obstetricians, Drs. Stephen G. Smith, and F. Janet Reid; attending gynecologist, Dr F. Janet Reid; consulting gynecologists, Drs. Stephen G. Smith, and Thomas C. Chowning; oculist and aurist, Dr. Edward T. Hornback, and pathologist, Dr. John N. Baskett.

NEW MEXICO.

New Sanitarium in Santa Fe.—Sister Ursula, superior of St. Vincent's sanitarium, Albuquerque, is planning to commence the erection of a new sanitarium in Santa Fe about April 1, 1903.

St. Joseph's Sanitarium.—Albuquerque now has a model nitarium, complete in every detail, large enough to meet the quirements of a large city, and furnished with the most improved equipment for hospital service. It has been erected at cost of nearly $50,000. The operating rooms were equipped the Bernalillo County Medical Association.

Tent City for Consumptives.—A tent city for consumptives to be established in the suburbs of Santa Fe. A tract of nd has been bought in the foothills southeast of the city, ith southern exposure, whereon will be laid out a model tent ty, with water supply, electric lights, telephone, sewer, etc., be a sanitarium on a new and large scale. A number of ew York health-seekers have already applied for tents.

Sanatorium at Silver City.—The new wing of St. Joseph's ospital, Silver City, which is to be used exclusively as a sanatorium for the treatment of pulmonary tuberculosis, has just been completed. The administrative work is in the hands of Dr. Earl S. Bullock, the bacteriologist first assigned to Fort Bayard by the medical department of the United States Army, and under his guidance there has been a gradual growth of the work. The accommodations soon became limited and with characteristic energy the Sisters built the addition to the hospital just opened, which is designed for ambulant patients.

NEW YORK.

Buffalo.

Term Opens.—The medical department of the University of Buffalo will begin its fifty-sixth annual session, September 29.

Vaccination of school children began Monday. The health commissioner supplies shields to each child vaccinated. Circulars of instruction as to the care of vaccinated arms, printed in English, German, Polish and Italian, will be sent to parents.

Emergency Staff Reorganized.—Because of the death of Dr. Clayton M. Daniels the Emergency Hospital staff has been reorganized as follows: President, Dr. John H. Pryor; vice-president, Dr. William C. Krauss, and secretary, Dr. Vertner Kenerson.

Personal.—Dr. George Roberts has returned from a five months' visit in Europe.——Dr. C. Stolzenbach of Hanover, Germany, has recently visited the city.——Dr. Jacob M. Kraus has gone to Denver, Colorado, for his health.——Dr. Max C. Breuer has returned from Europe.

The August mortality was at the rate of 16.86 per 1000 per annum. There were 47 deaths from pulmonary consumption, 76 from cholera infantum, 8 from typhoid fever, and 28 from cancer. Total deaths for August were 520 as compared with 551 for the corresponding month of 1901.

New York City.

Personal.—Dr. Allen Fitch, New York City, has resigned and will spend two years abroad in the study of insanity.——Nothing has yet been heard of Dr. William H. Bates, who so mysteriously disappeared August 30.

Spitting Ordinance to be Enforced.—Dr. Joseph H. Raymond, the assistant sanitary superintendent having charge of the Borough of Brooklyn, announces that he will rigidly enforce the ordinance prohibiting expectoration on sidewalks, railway platforms and other public places.

New Hospital in Jamaica.—A new hospital is to be established in Jamaica, Queens Borough. Rev. Henry Zimmer has donated a plot of ground 125 by 125 to the Dominican Sisters of Brooklyn as a site for the new building. The present plan is to build a modern hospital, with all equipments, to cost from $25,000 to $30,000.

An Interrupted Operation.—Just as a patient in the Polyclinic Hospital had been etherized and the first incision made for some operation on the intestine, an explosion in the sterilizing apparatus put the surgical apparatus out of commission. A hurry call was sent to Bellevue Hospital for an ambulance, and the wound having been hastily dressed the man was rushed at top speed to that hospital, and the operation completed. He died, however, in a few hours.

Thief in Bellevue.—An orderly in the interne's quarters of Bellevue Hospital has been arraigned in court on the charge of stealing clothing, jewelry and surgical instruments from members of the house staff. It is said that he has carried on his thefts for months, and that these stealings represent in value over two thousand dollars. When arrested there were upwards of fifty pawn tickets on his person, and a large assortment of surgical instruments was found at his lodging. He had formerly been a patient.

The Straus Milk Charity.—For the past twelve years, through the philanthropy of Mr. Nathan Straus, the poor have been supplied in the summer from numerous milk depots with Pasteurized and modified milk for infants. The Health Department records show that the mortality among infants under five years of age has steadily decreased during these years, and it is asserted that this diminution is most marked in those districts of the city in which this milk is most freely distributed. The summer mortality has been reduced about one-half, largely, it is thought, through the good work of this charity.

Fresh-Water Doctor Fined.—Adolph Grundman, sixty-three years old, who styles himself a "fresh-water doctor," was committed to the City Prison for thirty days in the Court of Special Sessions, September 11, on the charge of having practiced medicine without a license. Grundman was arrested on August 23 on complaint of Mrs. Mary Vlack of 349 Third

Avenue, who testified that her husband had been treated during July and August by Grundman, and that he had prescribed fresh water internally and externally. He supplied the water at $5 a pail, and four pails were used. There being no improvement in her husband's condition, Mrs. Vlack became suspicious and complained to the authorities.

Rigid Medical Inspection in the Schools.—So far, although only a portion of the children attending the public schools have been examined by the medical inspectors, about two thousand have been excluded because of some form of contagious disease. This has called forth indignant protests from the parents, but the Health Department announces that it is willing, so far as it is practicable, to treat medically such of these children as are too poor to receive the proper care from private physicians. The Health Commissioner has now very greatly reduced the number of school physicians, and has increased the salary four-fold. In return for this better compensation, each of these medical inspectors is now required to look after three schools, making daily visits to each school, and each day personally inspecting all of the scholars in one of these schools. In this way all public school pupils are to be inspected once every three days. The results have already amply justified the change, as under the old régime less than one-tenth of the number of cases of contagious disease would have been detected and excluded.

OHIO.

Cleveland College Opens.—The Cleveland College of Physicians and Surgeons, the medical department of Ohio Wesleyan University, held its opening session, September 17.

Niles City Hospital.—The Niles City Hospital Company has been organized with Dr. Thomas O. Clingan, president; Dr. Charles T. Swaney, vice-president, and Dr. Curtis C. Williams, secretary and treasurer.

Post-Graduate School in Cincinnati.—A movement is on foot to establish a post-graduate medical school in Cincinnati. The faculty will be composed of members of the faculties of Miami Medical College, and the Medical College of Ohio.

Tuberculosis Commission.—The governor has appointed the following commission to investigate as to the advisability of the establishment of a state sanitarium for tuberculosis: J. H. Outhwaite, Columbus; Max Senior, Cincinnati: Dr. Charles E. Slocum, Defiance: J. M. Rusk, McConnellsville; S. S. Knabenshue, Toledo; Cady Staley, Cleveland, and J. Warren Smith, Columbus.

PENNSYLVANIA.

Latrobe Health Board.—Drs. Joseph D. Casey and Lauren C. Thomas have been appointed members of the local board of health.

Uniontown Hospital.—At a meeting of the Uniontown Hospital Association, September 18, the contract for the erection of the building was awarded. The building is to be 143 by 90 feet, will accommodate 80 patients, and will cost about $65,000.

Philadelphia.

Low Mortality.—For the week ended September 20, 336 deaths were reported. This is a lower death rate than for any corresponding period for years.

Additions to Orthopedic Hospital.—New buildings, at a cost of $150,000, are being erected as additions to the Orthopedic Hospital and Infirmary for Nervous Diseases. They include a five-story and basement hospital building, a power house and basement kitchen.

Guggenheim Increases Gift.—Meyer Guggenheim of New York has added $20,000 to his gift of $60,000 for the erection of a hospital for private patients on the grounds of the Jewish Hospital, Philadelphia. The structure will be larger than originally planned. It is expected that not only this building, but the other new buildings of the same institution, the Loeb operating building and the Eisner building for nurses will be finished by Jan. 1, 1903.

GENERAL.

Change in Army Medical School Faculty.—Col. Calvin De Witt, assistant surgeon-general, U. S. A., is detailed as president of the faculty of the Army Medical School, to relieve Col. Charles Smart, assistant surgeon-general, U. S. A.

Health of Army Improves.—The report of the surgeon-general for the year ending June 30 last shows a gradual improvement in the condition of the health of the troops, notwithstanding many were subject to exposures of tropical service in the Philippines. Concerning the health of the troops in the islands, the report says:

> The character of service in the different parts of the archipelago has varied more during the year than in any similar period since American occupation. Although a great deal of hard field service has been done and much new country occupied, there has been a decrease in sick and mortality rates, for improved conditions in peaceful provinces have more than balanced conditions where there was active service.

Yellow Fever Germ Found.—The expected announcement of the yellow-fever germ is reported in the telegraphic news from New Orleans as given by Prof. George Beyer, of Tulane University. The commission sent by the U. S. Marine-Hospital Service has for several months been at Vera Cruz studying the epidemic which was of a particularly pernicious type, the mortality at one time reaching the frightful figure of 87 per cent. The germ of the disease was definitely found, and its character and habits fixed. It is of much higher order of life than had been anticipated, being an animal, not a vegetable organism. That found in the bodies of sufferers from the disease was identical with the germ found in the mosquitoes. During the epidemic at Vera Cruz the mosquitoes were especially numerous. The authorities of the Mexican city determined to inaugurate a war against the insects and appointed a committee, with Professor Beyer at the head, to exterminate the mosquitoes. The result of the war was that the number of cases of yellow fever were reduced one-half. Professor Beyer would not say whether the germ discovered at Vera Cruz was or was not the Sanarelli germ, but the belief is that it is a germ never before discovered.

Mosquitoes on Ships.—An investigation by the U. S. Marine-Hospital and Public Health Service has just been concluded by Surgeon H. R. Carter concerning the extent to which vessels are infected with yellow fever by mosquitoes. His conclusions are summed up as follows:

> 1. Vessels aboard which yellow fever had been contracted—i. e., vessels infected with yellow fever have not been rare, at least at Southern quarantine stations.
> 2. Such vessels are much rarer since 1893, and are not very common now.
> 3. That the diminution of the number of infected vessels reaching United States ports is due mainly to the sanitary measures for avoiding exposure to infection in the foreign ports, and to the substitution of steam for sailing vessels. To some degree the falling off of the vessels from Brazilian ports is also a factor.
> 4. That a case of yellow fever developing aboard a vessel plying between Southern ports of the United States and the tropics will probably infect the vessel so that other cases can, if time be given, be contracted aboard her.
> 5. Such vessels, however, if short trip vessels, not more than ten or twelve days en route after the occurrence of the case of yellow fever, will in general be disinfected at Southern quarantine stations before any other cases have been contracted aboard, although harboring infected mosquitoes.
> 6. That a case of yellow fever so occurring aboard a vessel from a Southern port of the United States would be able to infect her or not according to whether she had acquired the mosquitoes *Stegomyia fasciata* in the tropical port.
> 7. It is, in general, then necessary to disinfect all vessels running between Southern ports and tropical ports if a case of yellow fever occurs aboard, no matter where it be contracted, while vessels running between Northern ports and the tropics may, through precautions in tropical harbors, have no stegomyia aboard, and are thus not infectable by cases of yellow fever occurring aboard.

Smallpox.

Colorado: There were 9 cases reported in July, 7 of which occurred in Prowers County.

Connecticut: During August 12 cases were reported from 6 localities.——The secretary of the State Board of Health, in the August Bulletin, discusses the vaccination question as follows:

> The question of prime importance relating to public health at the present time is the prevention of the spread of smallpox. At no time in the history of the United States has this disease been more generally prevalent. It has occurred within the last few years in every section of the country between its ocean boundaries. As the cold weather approaches and compels the closing of dwellings, schools and factories, outbreaks of the pestilence will occur with increasing frequency in the towns and cities that have neglected the only effective means of arresting its progress, *namely, vaccination.* The exceptional mildness of the prevailing epidemic is a source of danger, rather than of safety. Its victims are sometimes so slightly ill that they travel in the trains, exchange visits with their neighbors, and even the doctors dispute the diagnosis.
>
> Innumerable instances of its communication in this manner are reported. Quarantine and disinfection of such instances are wholly impracticable. The only safety of any individual is by vaccination. The only protection for a community is vaccination. The fact of its protective power is as well settled as any fact in sanitary science. The exhaustive investigation of the whole subject of vaccination by the English Royal Commission and its final verdict, the experience of over 100 years in the practice of vaccination throughout the civilized world, and especially the results in European countries where vaccination is compulsory and the law is enforced, give unanimous testimony to its safety when properly practiced, and to its protective power.
>
> The only serious objections urged by the anti-vaccinationists can be avoided by well-known means. Nevertheless by the activity of

these objectors, their unscrupulous falsification of statistics, their unblushing mendacity and their sensational appeals to the fears and the prejudices of the credulous and uninformed, they have assumed a fearful responsibility in hindering the arrest of smallpox by their opposition to vaccination.

An instance of their misrepresentations is quite recent. They have announced and widely published that in the city of Cleveland, Ohio, smallpox had been stamped out by disinfection and without vaccination. The facts are, however, that instead of being stamped out, it so increased after stopping vaccination that Buffalo and other lake cities felt so much endangered by its prevalence there, that they "seriously considered the advisability of establishing a quarantine against it," and threatened that "unless immediate action be taken and results shown, quarantine will be instituted in a most vigorous manner."

This threat communicated to the State Board of Health of Ohio aroused its attention, and the Connecticut Board was informed by letter last week, from the secretary of the Ohio Board, that vaccination is going on at the rate of 10,000 per day in Cleveland.

The general vaccination of a community is in the interest of the taxpayer. The average cost of an epidemic of smallpox in a town is often many times what it would have cost for full protection from it. And with the epidemic comes the cost of both. It is well for prudent selectmen and city councils to think of this.

Illinois: Smallpox has been reported to the State Board of Health during the past week from DuBois, Washington County, and Chandlerville, Cass County.

Indiana: In one home in Monroe County there are seven cases of the disease. Many cases are said to exist in Ridgeville.

New York: The smallpox epidemic which has been afflicting Rochester since the latter part of last April has been stamped out. The Health Department report shows that the disease was brought to the city by two tramps from Troy, N. Y., about four months ago.

There have been 142 cases and 17 deaths from the disease, and 37 persons were detained at Hope Hospital at different times as suspects. The death-rate was 11.97.. In less than six weeks more than forty thousand persons were vaccinated. Of the $50,000 appropriated by the Common Council $28,000 was expended in fighting the disease. A curious incident of the epidemic was that 92 of the 142 cases were found in 22 families, 13 cases occurring in one family which did not believe in vaccination.

Ossining had three smallpox cases last summer, and now the village trustees are confronted with bills aggregating $5,210.30. A local doctor who took charge of the cases put in a bill for $2,000 for fifty visits made in twenty-five days, $40 a visit or $80 a day. The patients were kept in a houseboat anchored in the river. The boat, it is estimated, cost about $25, but the board of health agreed to pay $225 for it. In addition to this there is a bill of $189 for the use of a sailboat, power launch and towing. Two towboats cost $84. There is another charge of $50 for rent of another boat. The grocery and meat bills for patients amounted to $337.34, besides $33.75 paid to a hotel for persons kept out of their homes by the quarantine, making the total $371.09. The patients are said to have consumed $130.50 worth of whisky, about 2½ quarts a day. The clothing bill amounted to $182.38. In addition to all this the board has a bill of about $60 for building a pesthouse that was never used. A man who earns his living by fishing put in a claim for $200 for deprivation of the use of the beach.

Ohio: The health officer of Cleveland has invited John D. Rockefeller to provide a fund to be used in the search for the germ of smallpox. He has contended for some time that cats and dogs are the worst distributers of the smallpox germs that can be found. The hair of either animal may be filled with the germs and then a child may play with the pet. The result is another new case of smallpox. If the dog is permitted to run at large the danger is more than doubled. He has accordingly issued an order. The doctor insists that in all families where smallpox is discovered and where there is a dog or a cat the animal must be killed.——The Cleveland City Council has appropriated $40,000 to be used in combating the spread of smallpox.——At a special meeting of the Youngstown Board of Health, September 19, the following resolution prepared by Dr. W. L. Buecher was unanimously adopted: "Smallpox aging epidemically in Pittsburg and Cleveland, the board of ealth considers it its duty to advise the citizens of Youngsown to abstain from visiting those cities, except on necessary usiness, and the board of health strongly condemns the unning of excursion trains from and to these cities."

Pennsylvania: More than 50 cases of smallpox have ocurred at Rock Run, near Coatesville. Eight special officers have been detailed to enforce quarantine. Aid is asked from Philadelphia.——The Johnstown board of health has decided on the erection of a municipal hospital to cost $10,000 to replace the one above Morrellville, where an epidemic of smallpox exists, for which the hospital is blamed.

United States: Investigation shows that from Dec. 28, 901, to June 13, 1902, there were in the United States 36,373 cases of smallpox and 1,154 deaths resulting from the disease. As compared with the previous year there was an increase of 8,000 cases and nearly 600 deaths. In New York there were 1,522 cases and 233 deaths; Massachusetts had 1,088 cases and 146 deaths; Indiana, 1,346 cases and only 10 deaths; Kansas, 1,885 cases and 3 deaths, and Minnesota 6,940 cases and 31 deaths.

FOREIGN.

New Medical Institution at Frankfurt.—Frankfurt a. M. is planning the erection of an Academy for Practical Medicine, with which will be connected an official establishment for testing the new drugs and artificial foods put on the market every year. A laboratory for medico-clinical diagnosis is also to be a feature of the institution.

Advantages of a Medical Mayor.—Dr. Augagneur is mayor of Lyons, France, and has banished from the public places under his jurisdiction the advertisements of persons claiming to cure venereal disease. He has also vetoed all applications for the erection of projecting signs by magnetic healers, trance healers, massage establishments, etc., and revoked all previous permits for the same.

Supervision of the Teeth of School Children in Denmark.—The town of Frederiksberg in Denmark has hired a dentist to inspect the teeth of the school children regularly twice every year. Parents are notified by a printed circular whenever the teeth of their children are found to need attention. The supervision extends to both the public and private schools, and has proved a most salutary measure, as was officially announced with details at the recent Danish dental congress.

Medical School in Cochin China.—Our exchanges state that the French government has appropriated funds to found a medical school at Hanoi for the purpose of training native physicians and for the study of tropical diseases. The faculty will have oversight over the Pasteur Institute in Annam, a laboratory for the production of vaccine and serums, and for bacteriologic research, etc. A French hospital is also to be erected at Canton for the use of the natives, and $40,000 has been sent to the consul there for the purpose.

The International "Centralbureau" for the Crusade Against Tuberculosis.—This central committee comprises 120 men prominent in the campaign against tuberculosis. As already announced, it will assemble at Berlin October 22. The chief aim of the conference is to frame a constitution and define and discuss the questions of the day in regard to the white plague. Another feature of the assemblage will be the attempt to bring into co-ordination the so-called "wild tuberculosis congresses" and have the entire movement everywhere proceed along certain regular lines.

Deaths Abroad.—Don Federico Rubio, an eminent surgeon at Madrid, founder and editor of the imposing quarterly, *Revista Ibero-Americana de Ciencias Medicas*, and at one time ambassador from Spain to England. His clinic was a focus of light for Spain and Spanish America. *El Siglo Medico* remarks that his entire life was inspired with the "purest and most beneficent of all motives, the love of posterity." He was in his seventy-sixth year at the time of his death.——E. Teinturier, Paris, a prominent neurologist and writer, connected with the *Mouvement Médical* and the *Progrès Médical* since their foundation. He was particularly interested in the interpretation of miracles by the light of modern neurologic science and his works on this subject are well known.——B. Alcina, professor of therapeutics at Cadiz.——H. Dagonet, formerly professor at Strasburg and physician in chief of the asylums for the insane in the department of the Seine, which includes Paris.——R. A. Riant, Paris.——A. Graefe, Berlin, a member of the famous Graefe family of ophthalmologists.——L. Switalsky, privat docent of gynecology at Cracow.

The Cholera Epidemic in Egypt.—A pilgrim returning from Mecca managed to conceal the fact that he was ill and was passed by the quarantine authorities at Tor and allowed to proceed to his home in a remote village in Upper Egypt as being free from disease. Soon after his return home numerous cases of sickness developed in his village, but the fact that it was cholera was not recognized until 96 persons were affected. The vigorous measures then instituted had the effect of spreading the disease broadcast, as the natives abhor disinfection, isolation, etc., and at the first intimation of sickness fled to distant villages. Even in the houses in which deaths from cholera had occurred, and which were guarded by native sanitary officials, clothing and other articles gradually vanished. Some of these officials think that cholera was invented to provide them with a salary and opportunities for making a little pocket money. The disease is now epidemic, according to a report quoted by the *Allg. Med. Ct.-Ztg.*, in sixty places and in every province. About 90 per cent. of the cases terminate fatally, and as is readily seen from the official reports given weekly on the last page of THE JOURNAL, the condition is serious and growing worse. The prospects of the first Egyptian Medical Congress, organized for December of this year, are already blighted.

Correspondence.

Gastroptosia not Gastroptosis.

NEW YORK CITY, Sept. 15, 1902.

To the Editor:—In answer to the letters of Drs. N. O'Donnel Parks and William J. Robinson in THE JOURNAL of August 23, instead of writing a long letter I wish to refer to my paper "Greek in Medicine," read before the Book and Journal Club of Johns Hopkins University and published in this year's May number of *Johns Hopkins Hospital Bulletin*, translated also into Greek, German and Dutch. The translations appeared in Cyprus, Munich and Utrecht. It shall give me pleasure to send a report of the original or some of the translations to any colleague who will honor me by writing for them.

Here are some passages which are applicable to what my opponents have said:

"Twenty years ago, in an article which appeared in the *Berliner Klinische Wochenschrift*, Virchow said: 'Is it not justifiable at the present time to remind the physicians that they should use all possible exertion to show their scientific training in all, even in apparently small things? Is it not the first characteristic of a man of science that he should understand how to employ the language of science? The first thing by which the expert demonstrates his qualification is the correct use of technical terms; this especially causes respect for him, and nothing more enhances his utility'; and he closes his remarks with the wish that his views might be generally adopted. If we address this admonition to the medical profession at large we shall have to say: Would it not be justifiable at the present time to remind the profession to prove our science by establishing a scientific onomatology? The incorrectness of many of our medical terms can not be denied, but the extent of this incorrectness is larger than most of us have ever conceived; the evil is increasing every day, and the remedies thus far suggested have only brought confusion; they are not, and have not been, taken seriously; they have only brought discredit.

"It is not necessary to enumerate all the vain attempts at reformations of our onomatology; a single one, and I select the one which is most conspicuous at present, will suffice. We shall see why they were all of no avail, but we shall also see how we really can secure scientific onomatology which will stand as long as our science is taught, and which will be beyond all criticism."

I have to refer to the paper itself about the plan I have suggested.

"The facts I have presented to the Book and Journal Club of the Medical and Chirurgical Faculty of Maryland will, I am certain, find an echo in the medical profession. There exists a well-pronounced demand by all true men of science for purity and correctness of medical language. Professor R. Kossmann of the University of Berlin, whose name as a gynecologist is familiar to you, but who is not only a gynecologist, but has also distinguished himself as a philologist, says: 'In forming our pathological and surgical technical terms we can by no means dispense with Greek, and so long as we admit that the retention and introduction of Greek synonyms for pathological and surgical expressions is a necessity, we have for the sake of correctness and beauty of language to decide to go a step further, to do away with hybrid terms and establish pure Greek synonyms in their place. Whoever has familiarized himself with classical literature will find it more and more intolerable to name a scientific conception by a Greek- or Latin-like sounding word-monstrosity, especially when he knows the real Greek name.'"

If my opponents will look up the literature on the question of atonia gastrica they will see that the agitation for correctness of medical terms has not only a scientific but an eminently practical importance.

Further, if the gentlemen will look up the voluminous literature on this question since I have introduced it—if they will read the views of some of the most prominent men of our profession, they will certainly change their ideas and will perhaps regret to have pronounced them.

A. ROSE.

ASHTON, R. I., Aug. 28, 1902.

To the Editor:—Recurring to the inane controversy about appendicitis and perityphlitis, the latter word is itself a confession of ignorance on the part of those who use it. The word means inflammation in the neighborhood of, *περί*, about the cecum, *τυφλον*. "There is an inflammation somewhere," they say, "we do not know where, but it has reference to the cecum, anyway." They ignore the appendix, a rudimentary organ which has no other apparent object than to create trouble by exciting inflammation (perityphlitis). They fight about words; mistake the effect for the cause, temporize, mistreat the case, and the patient dies.

In another case a practical surgeon, unskilled in philology, is called in. He at once pronounces the case to be appendicitis, neither knowing, perhaps, nor caring for the derivation of the word, nor casting a thought on it or its meaning. He promptly operates, removes the peccant organ, cures his patient and saves a valuable life to the world.

To those philologists who object to the word appendicitis as being mongrel I would suggest a term which I fear will not be adopted. It is ekphyoskolekociditis, *'εκ*, out of; *φύω*, to grow; *σκώληξ*, a worm, and *ειδός*, form, which is almost a literal translation of appendix vermiformis from Latin into Greek, plus "itis." I am loth to assume the parentage of this word; it is uncouth; let it *go*: let appendicitis stand.

N. O'D. PARKS.

P. S.—In your issue of August 23 you made me sign myself H. instead of N. O'Donnel Parks. The man who printed my letterheads is responsible for this. The N does really look like H.

N. O. P.

Quack Advertisements and Religious Papers.

RIDGWAY, PA., Sept. 20, 1902.

To the Editor:—This last summer I drafted and presented to the official board of the First M. E. Church of this place, being a member of the board, a set of resolutions, drawing attention to the falseness of statements and dishonesty of purpose of various advertisers of "patent" medicines, and condemning the publication of such advertisements by the publishers of our church periodicals. The resolutions were passed, but two members of the official board voting against them. I took the ground that it was detrimental to the interests of the church that the papers should receive a profit from so false a business. Copies of the resolutions were sent to the various church publications circulating in this district. If necessary this move can be followed up to the annual and general conferences.

J. C. MCALLISTER.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

SODIUM GLYCOCOLATE IN DISEASES OF THE LIVER.

SHERWOOD, MD., Sept. 12, 1902.

To the Editor:—I have received a number of letters from readers of THE JOURNAL since the publication in the August 16 number of the article by Dr. T. W. Keown of Baltimore, entitled "Sodium Glycocolate in Diseases of the Liver," in which he mentions three cases of gallstones cured by me by the use of this remedy. The letters make inquiry of the particular preparation I have used in the treatment of these cases. Dr. Keown did not state in his article that the remedy I used was not a pure salt of soda and glycocolic acid but a mixture of salts formed with soda and all the bile acids. The preparation used by me is made by Dr. Herbert Richardson of Mt. Hope Retreat, Md., from the fresh liver of the bullock, and supplied me by Hynson, Westcott & Co., of Baltimore. I have not met with success with other preparations known as glycocolate of soda in the treatment of cholelithiasis. H. Burton Stevenson.

MALARIA WITH ANASARCA.

Arkansas City, Ark., Sept. 19, 1902.

To the Editor:—Replying to the query of Dr. Morse in The Journal of September 13; the anasarca caused by malaria is common, more common, however, is edema of the feet. A hydremic condition of the blood resulting from malarial cachexia causes this condition. For literature I would refer the Doctor to Tyson's Practice, First Edition, page 70; and to DaCosta's Physical Diagnosis, Eighth Edition, pages 831 and 959. Wilson & Ashton, in Sajous' Analytical Cyclopedia, Volume IV, page 318, also describe this condition, and in Eichhorst's Practice of Medicine, Volume 1, page 382, cachexia is given under the etiology of ascites.

Very respectfully, Vernon MacCammon, M.D.

ARTIFICIAL FOODS FOR INFANTS.

Detroit, Mich., Sept. 16, 1902.

To the Editor:—Your article on "First Aid Dangers" [Editorial, August 30, page 493] touches the spot. During the past ten years I have seldom reported a birth. The various makers of baby foods seem to have no difficulty in securing the addresses of the parents of the few I have reported and they have loaded them up with samples and literature of "how to feed the baby." One New York house has issued a small "Practice of Medicine for the Use of Mothers." Of course in its preface it states "that the work is not to displace the family doctor." Yet it carefully and fully gives diagnosis and treatment (with their products) of all the diseases of childhood. A great deal of credit is due to the makers of artificial foods for infants. Still I think a number of them should confine themselves to their specialty and leave to the physician diagnosis and treatment. Respectfully, E. T. Milligan.

State Boards of Registration.

North Dakota Report.—Dr. H. M. Wheeler, secretary of the North Dakota State Examining Board, reports the examination held at Grand Forks, July 1 to 3, as follows: Number of subjects, 13; percentage required, 75; written examination; total number examined, 22; passed, 19; failed, 3.

Book Notices.

Manual of Antenatal Pathology and Hygiene: The Fetus. By J. W. Ballantyne, M.D., F.R.C.P.E., F.R.S. Edin., Lecturer on Midwifery and Gynecology, Medical College for Women, Edinburgh. Pp. 527. Price, $7.00. Edinburgh: William Green & Sons. 1902.

The author of this volume is a widely recognized authority on the anatomy and physiology of the fetus and on teratology. In this work he gives his attention mainly to fetal physiology and pathology. In its preparation he has studied nearly three hundred specimens and has mastered all the important articles which have been published by other workers. As a collector of observations Dr. Ballantyne is comprehensive and accurate, and is always careful to distinguish facts from speculations. This volume must at once take an authoritative place among medical works. Apart from its value as a storehouse of observations, it is certain to serve as stimulus to all who desire to carry on original research. The author points out the many gaps in our knowledge of fetal physiology and pathology and suggests many lines of inquiry.

Handbook of Bacteriological Diagnosis for Practitioners, Including Instructions for the Clinical Examination of the Blood. By W. D'Este Emery, M.D., B.Sc. Lond., Lecturer on Pathology and Bacteriology in the University of Birmingham. Cloth. Pp. 215. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1902.

This little book, which is in size suitable to the pocket, was written, according to the author, for the general practitioner who has not had the opportunity furnished the rising generation to familiarize himself with the modern laboratory technic. As a result the work is quite elementary, and deals more with what the practitioner can and ought to do rather than with the details of how to do it. As a work of this class it does very well, but as it is not technical, it can scarcely be criticised along this line.

Marriages.

Leon Feingold, M.D., to Miss Rosalia Richter, both of Chicago, September 17.

Ernst Stuart Albee, M.D., Oshkosh, Wis., to Miss Harriet Altschul of Lima, Ohio.

Lee Stone, M.D., Sturgis, Ky., to Miss Eva Nall of Louisville, Ky., September 17.

W. W. Wood, M. D., Angola, Ind., to Miss Merle E. Sayler of Digby, Ohio, September 2.

Edgar S. Hooper, M.D., to Miss Emma Vickers, both of Darlington, Wis., September 3.

Xenophon Olsen, M.D., Vliets, Kan., to Miss Grace E. Johnson of Frankfort, Kan., August 27.

Felix Moraux, M.D., Luxemburg, Wis., to Miss Maggie Kiley of Green Bay, Wis., September 9.

Edward Bruce McDaniel, M.D., Baker City, Ore., to Miss Ellen Carlson of Chicago, September 13.

Albert W. Shaw, M.D., Buhl, Minn., to Miss Anna Laura Purdy of Minneapolis, Minn., September 24.

Joseph Rosenthal, M.D., Sault Ste. Marie, Mich., to Miss Fannie Ochsen of Philadelphia, September 10.

Hugh Schussler, M.D., Alton, Ill., to Miss Georgia Kober of Chicago, at West Alton, Ill., September 14.

Arthur Ruickoldt, M.D., New Haven, Conn., to Mrs. Emma Wetherbee of Burlington, Conn., September 9.

Joseph E. Westerlund, M.D., Cambridge, Ill., to Miss Emma C. Wahlberg of South Moline, Ill., September 10.

Guy L. Hunner, M.D., of the Johns Hopkins Medical School, Baltimore, to Miss Isabella Stevens, at Baltimore, September 10.

Siegfried A. Van Hoefen, M.D., St. Louis, Mo., to Miss Minnie Statler of Crawford County, Ark., at Kansas City, Mo., September 3.

Newberry A. S. Keyser, M.D., Bradshaw, Md., to Miss Caroline Blanche Rumsey, at Upper Falls, Baltimore County, Md., September 10.

James R. Barnett, Jr., M.D., Neenah, Wis., son of Dr. James R. Barnett of the same city, to Miss Agnes Chapman of Watertown, Wis., September 12.

Albert Solland, M.D., Los Angeles, Cal., to Miss Dagfine Svendsen of Southern Norway, at the residence of the bridegroom's parents in Chicago, September 17.

Deaths.

John W. Hughes, M.D., died at his home in Latrobe, Pa., September 11, from catarrhal pneumonia, after an illness of one month, aged 64. He was a prominent member of the Medical Society of the State of Pennsylvania and served as major and surgeon in the Civil war with the Fifth Pennsylvania Cavalry.

George H. Moore, M.D. Transylvania University, Lexington, Ky., 1884, who served during the Civil war on the Confederate side as surgeon of the Sixth Mississippi Cavalry, died at his home in Memphis, Tenn., September 16, aged 81.

William E. Higdon, M.D. College of Physicians and Surgeons, Kansas City, Kan., 1898, of Kansas City, Mo., died from typhoid fever, September 12, at the Sisters' Hospital, Kansas City, after an illness of four weeks, aged 35.

Henry D. Grindel, M.D. New York University, 1867, died at his home in San Diego, Cal., September 14, after a protracted illness, aged 75. He was a member of the San Diego County Medical Society.

Christopher M. Bell, M.D. College of Physicians and Surgeons, New York, 1865, a New York physician who retired from practice several years ago, died at Baden Baden, Germany, September 3.

Frederick G. Ibach, M.D. Jefferson Medical College, Philadelphia, 1879, died at his home in Mauch Chunk, Pa., September 11, from acute Bright's disease, aged 44.

John B. Du Kate, M.D. Louisville (Ky.) Medical College, 1871, died at his home in Vincennes, Ind., September 12, from Bright's disease, after a short illness, aged 60.

William B. Coburn, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1901, died at his home in Waterford, Me., September 9, from appendicitis, aged 29.

Martin Brown, M.D. Medical College of Ohio, Cincinnati, 1880, died suddenly in his rooms in Anderson, Ind., supposedly from apoplexy, September 17, aged 50.

John M. Wert, M.D. Jefferson Medical College, Philadelphia, 1880, died at his home in Philadelphia, September 13, after a lingering illness, aged 51.

George Lisle, M.D., the first white resident of Labette County, Kan., and the founder of Chetopa, died at his home in that place recently, aged 88.

Frank Lindsey, M.D., an old resident of Big Stone Gap, Va., died at his home in that place, September 13, after an illness of six months, aged 61.

Elbert A. Banks, M.D. Tulane University, New Orleans, La., 1868, an old practitioner of Columbus, Ga., died in Wynnton, Ga., September 9, aged 62.

Edmund H. Cook, M.D. Bellevue Hospital Medical College, New York, 1893, died at his home in Flushing, Long Island, N. Y., September 14, aged 39.

Mathias W. Mabry, M.D. University of Virginia, Charlottesville, 1842, died at his home in Augusta, Ga., September 9, aged 80.

William D. Eastland, M.D. Tulane University, New Orleans, La., 1892, of Vicksburg, Miss., died at Meridian, Miss., recently.

Miscellany.

Labyrinthitis After Administration of Salicylates.—Scheyer reports in *Wiener Med. Presse*, 1902, 22, the case of a laundress who was given .5 gm. sodium salicylate five times a day in treatment of a second attack of acute articular rheumatism three years after the first. After a week of this treatment symptoms of an affection of the middle ear developed and persisted notwithstanding suspension of the drug, resulting in permanent deafness, complete in one ear and partial in the other.

A Contortionist and His Medical Purchasers.—A man in Massachusetts, who was famous in his day as a contortionist of remarkable flexibility, several years ago sold his body (the goods to be deliverable after death) to a Detroit physician, who was anxious to study his skeletal formation; but after paying the money the physician died, and the heirs threw away that part of the estate as of no value to them. Another deal in futures was then made with a New York physician, but he also died. The contortionist, who is now nearly eighty years old and in excellent health, is said to be looking around for another purchaser.—*Med. Record.*

Diet in Smallpox.—According to N. S. Davis, Jr., anorexia, thirst and vomiting are noteworthy symptoms at the onset of this malady. Vomiting is usually not of frequent occurrence. Cool drinks should be given; indeed, water should be administered freely in all stages of the disease, both because it adds to the comfort of the patient, and because it will help to avert nephritis, which is an occasional complication. Febrile albuminuria is common. A liquid, non-albuminous diet will lessen or stop it. During the febrile stage a liquid diet, such as is usually prescribed in acute fevers, should be given—milk, broth, gruel, etc. Often the mouth and throat are so sore from the eruption that swallowing is difficult. Food must then be given in small portions at a time. Ice and ice cream are often grateful to patients at this time. Sometimes swallowing is so painful that rectal alimentation must be resorted to. It should not be relied on longer than is absolutely necessary, for when suppuration takes place on the skin, prostration develops rapidly, and is often very great. It is, therefore, necessary to give food by the mouth as steadily and in as large quantities as possible. Rectal alimentation must occasionally be utilized in order to help maintain strength when the stomach will not tolerate or digest food enough. Milk should be the staple article of diet. Gruels, weak tea, Mellin's food, farina and similar articles may be employed for variety. If there is no albuminuria, or if it is only trifling and transitory, bouillon, broths, raw or soft-cooked eggs, custards, and such dishes may also be used. If digestion is fairly good, as it is in mild cases, milk toast, soft-boiled rice or oatmeal, cornstarch pudding, blanc mange, gelatin jellies, finely mashed potato with meat-juice squeezed on it, may be given and will be relished. In the severer cases these articles may be given only during convalescence.—From Cohen's "System of Physiologic Therapeutics," Vol. VI.

New Instrument.

A STONE PHONENDOSCOPE TUBE.

HOWARD J. WILLIAMS, M.D.
MACON, GA.

Recently while examining a patient for stone in the bladder I wished to test the conductivity of the sounds by the phonendoscope placed over the suprapubic space while the searcher was being moved about in the bladder. The results were unsatisfactory, but the idea was suggested by the experiment of attaching the phonendoscope to the searcher.

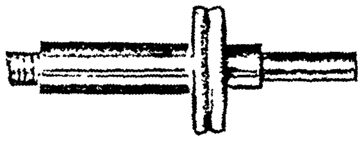

Figure 1.

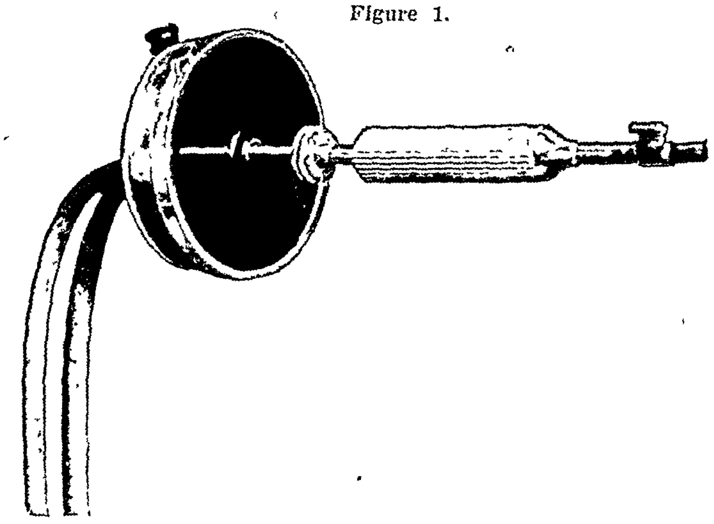

Figure 2.

A medium-sized screw was procured, the head and point of which being removed the shank fitted in the handle of a Thompson stone searcher, while the thread end caught snugly in the opening in the cardiac diaphragm of the phonendoscope. The connection being made, I repeated the examination and was rewarded by finding that the sounds were easily carried to the ear, intensified by the vibrations of the middle diaphragm of the phonendoscope.

I was so well pleased with this rough combination of the two instruments that I at once drew a design of a tube for attaching the phonendoscope to a Thompson searcher and had made the instrument illustrated in Figure 1. Figure 2 illustrates the two instruments attached by the tube ready for use.

Since the receipt of this tube, I have repeatedly tested the value of this manner of examination, both in the human bladder and by placing various foreign bodies of different characters in a rubber bag filled with water. In experimenting with foreign bodies in a bag full of water under cover, I find that not only the sounds reproduced by touching the bodies with the searcher are transmitted to the ear, but that the accentuation of the sound by the phonendoscope will reveal distinctly the physical characteristic note of each of the various bodies as the end of the searcher comes in contact with it, and further, that its size may be estimated by the duration of the sound produced as the searcher passes over it. In the human being, the rugæ of the bladder walls and the sizes of each, depending on the degree of distension of the viscus, can be noted, as the end of the searcher passes lightly over their surfaces while it is being turned about in the bladder, by a distinct muffled sound characteristic of the soft yielding mucous membrane. In the only other case of stone examined since the tube was made the characteristic click usually felt and heard in sounding was decidedly intensified by the phonendoscope and its size estimated.

I do not claim any originality in the principles on which the above instrument, if such it may be called, is made. Andrew's searcher and Billroth's sounding board attachment have long been known to the profession as acoustic aids in sounding the bladder for stone. Neither of these instruments will, however, as I know from personal experience, give the accentuated sound that the phonendoscope produces; while with either, the sound of the instrument, passing over the rugæ of a partially filled bladder, will often be mistaken for the muffled click of a soft stone. Both the phonendoscope and the Thompson searcher form part of every physician's armamentarium, while the little device above illustrated will be a material aid in the early accurate diagnosis of stone in the bladder by combining the use of two excellent instruments.

Societies.

COMING MEETINGS.

American Academy of Railway Surgeons, Kansas City, Mo., Oct 2-3, 1902.

Medical Association of District of Columbia, Washington, Oct. 7, 1902.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Birmingham, Ala., Oct. 7-9, 1902.

Idaho State Medical Society, Moscow, Oct. 9-10, 1902.

Vermont State Medical Society, Burlington, Oct. 9-10, 1902.

Mississippi Valley Medical Association, Kansas City, Mo., Oct. 15, 1902.

Conference State and Provincial Boards of Health of North America, New Haven, Conn., Oct. 28-29, 1902.

Missouri State Anatomical Society.—This body met at St. Joseph, September 12, and elected Dr. Wallace B. Deffenbaugh president and Dr. Harry S. Forgrave secretary, both of St. Joseph.

American Public Health Association.—The thirteenth annual meeting of this association will be held in New Orleans, December 8 to 12, under the presidency of Dr. Henry D. Holton, Brattleboro, Vt.

Mecosta County (Mich.) Medical Society.—The physicians of the county have met at Big Rapids and organized this society with Dr. Joseph McNeece, Morley, as president, and Dr. Franklin C. Terrill, Big Rapids, secretary.

McLeod County (Minn.) Medical Society.—Medical men of the county met in Hutchinson, September 10, and organized a county medical society with the following temporary officers: Dr. Kee Wakefield, Hutchinson, president, and Dr. Frank E. Burch, Glencoe, secretary.

Livingston County (Mich.) Medical Society.—The physicians of the county met at Howell, September 16, and organized this society, with Dr. William J. McHench, president; Dr. Abel S. Austin, Fowlerville, vice-president; and Dr. R. H. Baird, Howell, secretary and treasurer.

New Hampshire Surgical Club.—The annual meeting of this organization was held in Centre Harbor, September 6. Dr. Arthur C. Heffenger, Portsmouth, was elected president; Dr. Charles R. Walker, Concord, vice-president, and Dr. Nelson W. McMurphy, Concord, secretary-treasurer.

Paducah (Ky.) Medical and Surgical Society.—This society had its final meeting, September 10, wound up its affairs and disbanded. As soon as this had been done the members organized the McCracken County Medical Society, which will be in affiliation with the Kentucky State Medical Society.

Central Michigan Medical Society.—This society, at its meeting, held at Lansing, September 11, voted to effect a reorganization under the name of the Ingham County Medical Society. This is in accord with plan proposed by the American Medical Association for the uniform organization of county societies.

McCracken County (Ky.) Medical Society.—The reorganization of this society was completed September 10, at its meeting in Paducah, when Dr. Shandy Z. Holland, Grahamsville, was elected president; Dr. R. Holt. Ragland, vice-president; Dr. Horace T. Rivers, Paducah, secretary, and Dr. Thomas E. Moss, Jr., Woodville, treasurer.

St. Louis Medical Society of Missouri.—A special meeting was held, September 13, at which appropriate resolutions were adopted on the death of Prof. Rudolph Virchow, who was an honorary member of the society. Short addresses were delivered by Dr. Hugo Summa, on "Virchow as a Pathologist," and by Dr. Frank J. Lutz, on "Virchow in Public Life."

Caledonia County (Vt.) Medical Society.—The physicians of the county met at St. Johnsbury, September 8, and organized a society to affiliate with the Vermont State Medical Society. Dr. Lorenzo W. Hubbard, Lyndon, was elected president; Dr. Oscar E. Carter, Danville, vice-president; Dr. Walter J. Aldrich, St. Johnsbury, secretary, and Dr. J. M. Gibson, McIndoe Falls, treasurer.

Hillsdale County (Mich.) Medical Society.—Twenty-five physicians of the county met at Hillsdale, August 28, and organized this society, which will be in affiliation with the Michigan State Medical Society. Dr. Bion Whelan, Hillsdale, was elected president; Dr. Daniel W. Fenton, Reading, vice-president; Dr. Herbert H. Frazier, Moscow, secretary, and Dr. William R. Dittmars, North Adams, treasurer.

Wyoming State Medical Society.—This society held its annual meeting at Cheyenne, September 9 and 10. The following officers were elected: President, Dr. Samuel B. Miller, Laramie; vice-presidents, Drs. John H. Conway, Cheyenne, and Mortimer Jesurun, Douglas; secretary, Dr. Harry S. Finney, Rawlins, and treasurer, Dr. Joseph L. Wicks, Evanston. Rock Springs was selected as the meeting place for 1903.

Northern Tri-State Medical Association.—The annual convention of this body was held in Coldwater, Mich., September 16. Dr. William F. Shumaker, Butler, Ind., was elected president; Dr. Howard M. Byall, Montpelier, Ohio, vice-president; Dr. John R. Williams, White Pigeon, Mich., secretary, and Dr. Arthur G. Holbrook, Coldwater, Mich., treasurer. The association will next meet at Butler, Ind., in 1903.

Oakland County (Mich.) Medical Society.—The physicians of this county met at Pontiac, September 10, and organized a county society to be in affiliation with the Michigan State Medical Society. The following officers were elected: President, Dr. Franklin B. Galbraith, Pontiac; vice-president, Dr. De Witt C. Wade, Holly, and secretary, Dr. William Mc Carroll, Pontiac. The society has an initial membership of thirty.

Oregon State Medical Society.—At the annual meeting of this society held in Portland, September 10, 11 and 12, the proposed new constitution was passed and the following officers were elected: President, Dr. Henry W. Coe, Portland; vice presidents, Drs. F. W. Van Dyke, Grant's Pass; J. A. Geisendorffer, The Dalles, and James P. Tamiesie, Hillsboro; secretary, Dr. Alexander D. Mackenzie, Portland, and treasurer, Dr. Mae H. Cardwell, Portland.

Wayne County (Mich.) Medical Society.—This society held a public memorial meeting in honor of Prof. Rudolph Virchow. After introductory remarks by the president, Dr. Samuel Bell, addresses were delivered on "Gross Pathologic Work Pertaining to Tumors," by Dr. Theodore A. McGraw; "Benefits Resulting to Science as a Result of His Microscopic Research Work," by Dr. Heneage Gibbs; "Virchow as a Teacher," by Dr. Max Ballin; "Benefits Accruing to Internal Medicine," by Dr. Johann Flinterman, and "Virchow as a Public Benefactor," by Dr. John J. Mulheron.

Conference of State and Provincial Boards of Health of North America.—The next meeting of the conference will be held at New Haven, Conn., October 28 and 29, under the presidency of Dr. Henry M. Bracken, St. Paul. The following are the topics for discussion: "Presentation of a List of Diseases which are Considered as Communicable"; "Resolutions in Regard to the Control of Yellow Fever"; "Rules Governing the Transportation of Dead Bodies"; and "An Expression of Opinion in Reference to the Action Taken by the Health Officers in San Francisco in the Sanitary Control of the Plague."

Rocky Mountain Interstate Medical Association.—At the annual meeting of this association, held in Cheyenne, Wyo., September 9 and 10, the following officers were elected: Dr. Charles H. Soller, Evanston, Wyo., president; Drs. George P. Johnston, Cheyenne, Wyo., and Uhler D. McDowell, Longmont, Colo., vice-presidents; Dr. Elias S. Wright, Salt Lake City, Utah, treasurer; Dr. Henry La Motte, Salt Lake City, Utah, recording secretary, and Dr. Samuel D. Hopkins, Denver, Colo., corresponding secretary. The 1903 meeting will be held in Salt Lake City. In his annual address, the president, Dr. R. Harvey Reed, Rock Springs, Wyo., strongly advocated the establishment of an interstate board of medical examiners under national supervision, there being a board in each state appointed by the national government. This would entitle a physician practicing in one state to practice in all others where at present he must pass an examination in moving to a new state.

SECOND INTERNATIONAL CONFERENCE FOR THE PREVENTION OF SYPHILIS AND VENEREAL DISEASES.

Held at Brussels, Belgium, Sept. 1 to 6, 1902.

(From Our Special European Correspondent.)

Importance of Subject.

Without doubt one of the widest and most important subjects in the entire domain of medicine is that of the venereal diseases. Bound up in their study purely as topics of medical interest, there are many unknown and questionable problems, but when viewed in the larger social sense the complexity of their study becomes almost appalling. It is peculiarly fitting, therefore, that an international society should have been formed, and it is further a subject of great congratulation that it has had so propitious a beginning under the most generous and appreciative support of the Belgian government.

Delegates.

The representatives were gathered from all the countries of the civilized world, and the United States government was most ably represented by Drs. Valery Havard, U. S. Army, and Ezra Z. Derr, U. S. Navy. Among the members of the profession from this country were Drs. John Van der Poel, Ferdinand C. Valentine and Smith Ely Jelliffe, delegate from the American Medical Association, all of New York City. The medical profession were in the majority, but jurists, legislators, editors and delegates from benevolent and charitable societies, representatives of the police, etc., all contributed to give not only a distinctly cosmopolitan character to the gathering, but also gave the discussions a fulness and many-sidedness rarely found in such congresses. This tended to render the work of this conference less clear cut and decided than many of the members desired, but it had the advantage of showing the many-sided character of the questions under discussion and the desirability of making true progress.

The Work of the First Congress.

In the first congress, held three years before in Brussels, many preliminary subjects were discussed and settled to the satisfaction of all the members. These included the determination by:

1. General reports by leading specialists of the dangers to society of (*a*) syphilis; (*b*) gonorrhea; (*c*) the part that prostitution plays in the propagation of these maladies; (*d*) modes of dissemination other than prostitution.

2. To ascertain by joint study the condition of prostitution; the degree of frequency of venereal disease; the prophylactic measures taken to diminish these affections; the laws concerning prostitution, state, municipal, preventative or repressive; the police or medical supervision; opportunity for treatment in hospitals, and medical instruction concerning venereal maladies.

3. To consider six definite question: (*a*) *Have those systems* of official regulation which have been in vogue had an appreciable influence in the diminishing of venereal diseases? (*b*) How can the medical supervision of prostitution be made more effective? (*c*) From a purely medical viewpoint would it be of advantage to tolerate houses of prostitution or should these be suppressed? (*d*) In what manners can police regulation of prostitution be improved? (*e*). By what legal means might the number of women who try to make a living by prostitution be diminished? (*f*) What general measures can be taken to combat the spread of syphilis and venereal disease apart from those concerning the prostitute?

In the discussions held in 1899, it was shown that only by an international conference could any advance be made, and a large number of dependent issues were definitely settled. The larger questions of ways and means to be adopted effectively to combat the diseases were left, however, in as unsettled a manner as ever. Among the conclusions reached by the first conference may be mentioned the following: That municipal control of prostitution as practiced has not been a success; that the prostitution of minors, of all the forms of prostitution, is the most dangerous, both as moral and medical factors; that present modes of instruction in venereal diseases, both for the student of medicine and for the laity, are in part insufficient, unthorough and unpractical and that the statistical studies bearing on venereal diseases need to be established on more uniform lines if valuable comparisons are to be deduced therefrom.

Scope of Work.

Narrowing the field down as did the discussions of the first conference, the program of the second international meeting *specially took up three main questions.* The discussions were most active concerning that of public prophylaxis; the other questions, individual prophylaxis and statistics, were relegated to a subordinate position. The program outlined the following scheme:

Public Prophylaxis.

In that it has been a recognized function of the state to protect its citizens from the ravages of contagious diseases which by their frequency, or by the ease with which they are communicated, constitute a public danger, and further, to protect minors abandoned by their families:

A. What legislative action should be taken against venereal diseases, especially concerning 1, prostitution, (*a*) of minors; (*b*) maintenance of public peace and morality: (*c*) procurers and procuresses. 2. Apart from prostitution, (*a*) for the protection of minors of both sexes; (*b*) for the organization of free medical treatment in hospitals and by private charities; (*c*) for the control of wet nurses, of infection by midwives and nurses, of infection by arm-to-arm vaccination, of industrial infections; for the protection of servants in employment bureaus, lodging houses and hotels.

B. Should the transmission of venereal diseases be made a penal offense?

Individual Prophylaxis.
